UNLEAVENED BREAD, Use of, in the Eucharist, has long been a subject of controversy between the Latin church on the one hand and the Greek and other oriental churches on the other; with the latter of whom the reformed churches in later times have conformed in their practice of celebrating the Lord's supper. The early history of the usage is very obscure; but the western church had certainly, from a very remote date, employed *azyms*, or unleavened bread, in the consecration and distribution of the Eucharist; nor was this usage made a subject of controversy with the Latins by Photius, on occasion of the dispute between the churches, which arose during his patriarchate. In the later controversy, however, under Michael Cerularius (see Greek Church), the question of azyms became very prominent, and the diversity of practice still continues a subject of controversy between the Greeks and Latins. The principal argument alleged by the advocates of the use of leavened bread is founded on the assumption that the last supper of our Lord took place on the eve of the Passover, that is, on the 13th day of the month Nisan, on which day common bread and not the azyms, must have been used; and on this and some other grounds, some writers, even among the Roman Catholics themselves, and especially the learned Jesuit Sirmond, have maintained that the last supper was actually celebrated in leavened bread. On the other hand, however, it is contended that the last supper, being held in the evening of that day, was, in the strictest sense, our Lord's celebration of the Passover, and therefore (Exodus, xii. 8–20), that the bread can have been no other than azym, or unleavened. It must be added that all Roman Catholic writers, and the more learned among the Greeks, are agreed that the Eucharist may be *validly* consecrated whether the bread be leavened or unleavened.

UNLUCKY DAYS. See Day or Days.

UNST, the most northern of the Shetland islands, in lat. 60° 45′ n., is 12 m. long, and 5 m. in average breadth; area, 36 sq. m.; pop. '91, 2269.

UNTERWALDEN, one of the four Waldstätten, or forest cantons of Switzerland, comprising the two half cantons of Nidwald and Obwald (see Switzerland). It is 25 m. in length by 21 m. in breadth, and has an area of 295 sq. miles. In 1870 the pop. was 26,116; in 1894 it was 27,771. Unterwalden is bounded on the e., s., and w. by lofty hills, and subsidiary ridges divide it into two parallel valleys—both of which open on the n. into the lake of Lucerne. The eastern valley is drained by the Engelberger Aa, the western valley by the Sarner Aa. Great highways run up these valleys from the shores of the lake, and in several places communicate with each other; but they do not connect Unterwalden with surrounding cantons. The canton is chiefly pastoral. The capital of the Nidwald is Stanz (pop. '88, 2458), remarkable for its fine church and statue of Winkelried.

UPANISHAD is the name of those Sanskrit works belonging to the Vedic literature which contain the mystical doctrine of the Hindus on the nature of a supreme being, its relation to the human soul, and the process of creation (see India, sec. *Religion*). The word (derived from the Sanskrit prefixes *upa*, "beneath," or "near," and *ni*, "in," combined with the radical *sad*, "sit") is explained by the great theologian, *S'ankara* (q.v.), and others after him as meaning the "science of Brahman," or "the understanding of the identity of Brahman and the soul," because "in those devoted to it, this science *sets to rest* (or destroys) the world, together with (ignorance) its cause; or, in other words, because it shows to them that the world has, besides Brahman, no reality; Grammatical commentators explain its etymology as implying that "eternal bliss *reposes on it* (*upanishîdati s'reyo 'syâm*);" and Prof. M. Müller has surmised that the word "Upanishad meant originally the act of sitting down near a teacher, of submissively listening to him," whence it came to mean "implicit faith, and at last truth or divine revelation." But apart from the artificialness of all these interpretations, it deserves notice that the earliest sense of the word appears to be that of "secret" or "mystery" (literally, "that which *sits* or rests *beneath*"). Is this sense, it is mentioned by the grammarian Pân'ini; and as it is very probable that, in his time, the works bearing the name of Upanishads were not yet in existence (see Goldstücker's *Pân'ini*, etc., p. 141), it may be assumed that these works derived their name from the mysteriousness of the doctrine contained in them; and perhaps also from the mystical manner in which they propounded it.

In order to understand the origin and purport of the Upanishads, as well as the relation in which they stand to the Vedas, properly so called, it must be borne in mind that, though the Vedic hymns are based on the worship of the elementary powers, and the Brâhman'a portion connected with them is chiefly concerned in legendary and ritual matter relating to that worship, yet in both these portions of the Vedas, and especially in the Brâhman'as, the beginnings of a period become already visible when the poets raised the questions as to the origin of the world and the true nature of the gods. See INDIA, sec. *Religion*. A first attempt at a systematic answer to these questions was made in works which bear an intimate relation to the Brâhman'as; and so great was the awe in which, on this account, these works were held, that they had to be read in the solitude, where the mind could ponder in perfect calmness over the mysterious problems in which they are engaged. These are the *Aran'yakas* (from *aran'ya*, a forest.) But as the style and contents of the Aran'yakas are extremely obscure, and as, through the close alliance of these works to the Brâhman'as, of which some of them form part, the theological questions of which they treat are much overlaid with ritual and other matters which properly belong to the Brâhman'as, a further progress made in the same direction, led to the composition of works and treatises, the diction of which is somewhat clearer and less entangled with subjects extraneous to the problems they intend to solve. Such works and treatises are the *Upanishads*. Their object, like that of the Aran'yakas, is to impress the mind with the belief in one supreme spirit (*Brahman*, as a neuter, and different, therefore, from the same word as a masculine, which is the name of the first god of the *Trimûrti*, q.v.), to show that this supreme spirit is the creator of the world; that the world has no reality if thought of besides Brahman, and that the human soul is identical in nature with that same spirit whence it emanates. The reward the Upanishads hold out to the believer, who understands their doctrine, and firmly adheres to it, is freedom from transmigration (q.v.), and consequent eternal bliss. The object and aim of the Upanishads are therefore the same as those propounded in the philosophical systems (see SANSKRIT, sec. *Literature*); and the Upanishads may therefore be looked upon as the forerunners of these systems themselves—those Upanishads, at least, which we may call the older Upanishads; for as to the more recent ones, and those which bear the stamp of a sectarian character, their claim to be ranked among the Vedic writings is extremely doubtful, if at all admissible.

Though agreeing in the main points of their doctrine, it is easily understood that works of this nature, ranging over different periods of Hindu religion, will also differ from one another both in the manner and detail in which they deliver their subject-matter, and in the degree of completeness with which they treat of it. Thus, in some, the legendary narrative, and even ritual detail, are still considerably blended with the theosophical speculation—and these stand nearest, therefore, the Aran'yakas, probably also in time; in others, more philosophical, the nature of Brahman and the human soul is the only subject of inquiry, in others, the process of creation is also enlarged upon, with detail which harmonizes more or less either with the ulterior views of the Vedânta (q.v.) or those of the Sa'nkhya (q.v.) philosophy; some Upanishads, again, especially emphasize the inefficiency, for the attainment of eternal bliss, of the performing religious acts and of worldly studies—the knowledge of Brahman being the only means that leads to this end; others, on the contrary, in conformity with the Yoga (q.v.) doctrine, assign a prominent place to the exterior means, by using which the soul would qualify itself for union with the supreme spirit; while the sectarian Upanishads, which identify this spirit with Vishn'u and S'iva, have, besides, the tendency of reconciling the popular with the philosophical creed.

Of the older Upanishads, a typical instance is furnished in the Chhândogya Upanishad of the Sâmaveda, the framework of which is legendary throughout, and its contents allegorical and mystical. Other shorter Upanishads, freer from narratives and allusions to the mysterious import of ritual acts, aim at a more intelligible exposition of the doctrine of the soul. Of their mode of treatment, the following passage from the *Kât'haka* Upanishads will serve as an example; *Nachiketas*, the son of Vâjas'ravas, having come to the abode of Yama, the judge of the dead, and obtained from him the grant of three boons, asks of him, for his third boon, an answer to the following question; "There is this doubt: some say that (the soul) exists after the death of a man (in connection with another body than this); others say that it does not. This I should like to know, instructed by thee." And Yama, after some hesitation, explains to him that the soul and Brahman are one, but that a man attains immortality only by understanding this unity, and that, to arrive at this understanding, he must free his mind from sensual desires, and get a correct knowledge both of the nature of Brahman and of the soul. "Know the soul as the rider, and the body as the car; know intellect as the charioteer, and *manas* (the organ of volition) as the rein. The senses, they say, are the horses, the objects (their) roads; and the enjoyer (i.e., the rider) is (the soul) endowed with body, senses, and manas. Thus say the wise. If he (the charioteer) is unwise, and his manas is always unbridled, his senses are uncontrolled like vicious horses; but if he is wise, and his manas is always bridled, his senses are controlled like good horses. He who, always impure, is unwise, and whose manas is unbridled, does not attain *that* abode (of immortality), but comes to the world (of birth and death), he, however, who, always pure, is wise, and whose manas is bridled, he attains *that* abode whence he is not born

again. The man who has a wise charioteer, and whose manas is bridled, reaches the other shore of the road (of the world), the highest abode of Vishn'u. Higher (i.e., subtler), indeed, than the objects are the senses; higher than the senses is manas; higher than manas, intellect; and higher than intellect, the great one, the soul. Higher than the great one is that which is unmanifested, and higher than the unmanifested is Purusha, the supreme spirit. But higher than Purusha there is nothing; he is the goal, the highest resort. This highest spirit is the soul hidden in all created beings; it is not manifest, but is beheld by those who can see what is subtle with an attentive, subtle intellect." The coincidence between the allegory, in the foregoing passage, and that in Plato's *Phædrus*, imparts an additional interest to this Upanishad, which is valuable, moreover, on account of the evidence it affords as to points of agreement and difference between its views of the development of the world and those expounded in the Sânkhya (q.v.). The *Mun'daka* Upanishad is important for the relative position which it assigns to the teaching of the Vedas, and the doctrine of the Upanishads. "Two sciences," it says, the knowers of Brahman tell us, "must be known, the higher and the inferior. The inferior is (the knowledge of) the R'igveda, the Yajurveda, the Sâmaveda, and the Atharvaveda, the knowledge of pronunciation, the ritual, grammar, explanation of Vedic texts, prosody, and astronomy. But the higher knowledge is that by which that imperishable Brahman is comprehended. That which is invisible, unseizable, without descent (or origin), without either color, eye, or ear, without hand or foot, eternal, manifold (in creation), all-pervading, very subtle, undecaying—the wise behold it as the cause of created beings." And in another place the performers of the sacrificial rites ordained by the Veda are said to attain, indeed to Indra's heaven in virtue of their pious work; but this state of bliss is declared to be unstable and perishable, and these "fools . . . . drop (from their heaven) as soon as this heaven (the reward of their acts) has faded away. Fancying that pious acts, ordained by the Vedas and codes of law, are the highest (object of man), these ignorant people do not know that there is something else which leads to eternal bliss. Having enjoyed (the reward of their deeds) on the happy summit of paradise, they enter again this world, or one that is (even) lower. Those, on the contrary, who practice penance and faith, and, with subdued desire, live in the forest, under the vow of a religious mendicant, they, free from sin, enter through the sun to that abode where resides that immortal spirit, that spirit, indeed, of undecaying nature."

The *Talavakâra*, or *Kena*, Upanishad, which, being one of the shortest, is in form one of the most philosophical treatises of this kind, puts in clearer language, perhaps, than any other Upanishad, the doctrine that the true knowledge of the supreme spirit consists in the consciousness which man acquires of his *incapacity* to understand it, since the human mind being capable only to comprehend finite objects, cannot have a knowledge of what is infinite.

The Upanishads are not supposed to have been revealed in the same manner as the Vedic hymns. See VEDA. Nevertheless, with the exception of a few confessedly modern Upanishads, they are not assigned to human authorship, but looked upon as inspired writings, to which the term *S'ruti* (q.v.) applies. In several Upanishads, no special mention is made of their divine origin; in some, however, this is done. Thus *Chhándogya* Upanishad, in its concluding section, relates: "This (knowledge of the soul) Brahman (the god of the Trimûrti) imparted to Prajâpati (a lord of creation—the patriarch Kas'yapa, as S'ankara explains); Prajâpati imparted it to Manu, and Manu to mankind; the *Br'ihadâranyaka* Upanishad which on three occasions gives long lists of teachers who handed it down to their pupils, always ascribes itself, in the last instance, to the authorship of "the self-existent Brahman (the supreme spirit); and in a similar manner the *Mun'd'aka* Upanishad says that it was Brahman (the god of the Trimûrti), the creator of the universe, who first taught the science of the supreme spirit to his eldest son, Atharvan. As in the case of most ancient works of Sanskrit literature, the date of the Upanishads also still remains quite uncertain, and, wherever given, is purely conjectural. According to the native system, they are classified as belonging to one or the other of the four Vedas, with which they are held to stand in immediate connection. There are Upanishads, consequently, of the R'ig-, Yajur-, Sâma-, and Atharvaveda. But this classification has no reference whatever to chronology. For a fuller account of these works, see Prof. Weber's *Indische Studien*, vols. i. ii. (Berlin, 1850–53), and his *Akademische Vorlesungen über Indische Literatur-geschichte* (Berlin, 1852); Prof. M. Müller's *History of Ancient Sanskrit Literature* (Lond. 1860); John Muir's *Original Sanskrit Texts*, vol. i.–iv. (Lond. 1858–63); and the edition and translation of several of these Upanishads by E. Roer, *Râjendra Lâla Mitra*, and E. B. Cowell, in the *Bibliotheca Indica*; also Raja Rammohun Roy's *Translation of several Principal Books, Passages, and Texts of the Veds* (Lond. 1832). The names of 149 Upanishads, as compiled from various sources by Prof. M. Müller, may be found in the *Zeitschrift der Deutschen Morgenländischen Gesellschaft*, vol. xix. p. 137, ff.

UPAPURAN'A. See PURÂN'A.

U'PAS (the Malay word for *poison*) is the name given to a number of vegetable poisons in the Eastern archipelago and the Philippine islands. The most celebrated poison of this kind is produced by the *antjar* (*antiaris toxicaria*), a tree which grows in the Sunda and Philippine islands. It attains a height of upward of 100 ft., and belongs

to the natural order ARTOCARPACEÆ (q.v.), the same order with the bread-fruit. The leaves are lanceolate. The female flowers are solitary; the male flowers congregated beneath them in numbers upon the receptacle, which has a long stalk, and is of the shape of a watch-glass. The fruit is a kind of drupe, covered with fleshy scales. From the milky juice of this tree (called in some of the islands *pohon-upas antjar* in Java and *ipo* in the Philippines), mixed with black pepper, and the juice of galanga root and of ginger, the Malays prepare a poison for their arrows, which proves speedily fatal to men and to the larger mammalia. The only hope of relief is by means of severe vomitings and the excitement of profuse perspiration. Although the fresh juice of this tree, brought into contact with the skin, acts as a poison, the story of a poison-vale in Java, in which the exhalations of numerous poison trees extinguish all animal life, and even all other vegetable life, is a mere fable. There is a narrow valley in Java where neither animal nor vegetable life can subsist, but this is owing to carbonic acid gas emitted from the ground, as in the *Grotto del Cane*, near Naples, and the upas-tree is as incapable of living there as any other. It is found in forests, and does no harm to the other trees around it. The prepared upas or antjar poison is kept in close tubes of bamboo, and is of the consistence of molasses. The flesh of animals killed by this poison may be eaten with perfect safety; although the virulence of the poison is shown by its extremely rapid action. It is not perfectly known what the substance is which gives to the juice of the upas tree its poisonous properties, but it appears to be an alkaloid. The fiber of the bark of the upas tree is sometimes made into cloth, but unless the fiber is thoroughly cleaned, garments made of it produce a painful itching. A still more powerful poison than the upas antjar, employed in the same part of the world, is the *upas tjettek* or *upas tieute*, which is prepared in a similar manner from the root of the *strychnos tieute* (see STRYCHNOS). It abounds in strychnine.

UPHAM, CHARLES WENTWORTH, 1802–75; b. St. John, N. B.; graduated at Harvard college, 1821, and at the divinity school, 1824; ordained colleague pastor with rev. John Prince of the First Unitarian church, Salem, Mass.; relinquished the ministry on account of loss of voice in 1844. He edited the *Christian Review* and *Christian Register;* was mayor of Salem, 1852; several times member of the legislature; president of state senate, 1857–58; member of congress, 1853–55. He published *Letters on the Logos; Lectures on Witchcraft; Life of Sir H. Vane; Life of J. C. Fremont; Prophecy as an Evidence of Christianity.*

UPHAM, THOMAS COGSWELL, D.D., 1799–1872; b. N. H.; graduated Dartmouth college, 1818; Andover theological seminary, 1821; assistant teacher of Hebrew; colleague pastor of the Congregational church, Rochester, N. H., 1823–24; professor of mental and moral philosophy, and instructor in Hebrew, Bowdoin college, 1825–67. He published, *Elements of Mental Philosophy; Treatise on the Will; Principles of Interior or Hidden Life; Ratio Disciplinæ; Treatise on Divine Union; The Life of Faith.* His writings are deeply spiritual, and though their philosophy tends to mysticism, are quickening and suggestive.

UPHEAVAL or **UPTHROW OF STRATA,** the change in stratified rocks from their original horizontal position to one more or less inclined, produced by an expansive subterranean force, or other power, like the pushing forward of the crust itself, as in the case of the Appalachian mountains (q.v.). In slight changes of level, the continuity of the rock is unbroken; but frequently immense cracks are formed, into which igneous rocks penetrate, and form a backbone for the upraised mass, or dikes penetrating the strata.

UPHOLSTERY, that branch of trade which relates to the furnishing of a house with curtains and other kinds of hangings. It is also applied more generally, and is made to include bedding, carpeting, and the covering of chairs, couches, etc.

UPJOHN, RICHARD, 1802–78; b. England. He emigrated to the U. S., 1829, and soon became known as an architect; settled in New York, 1835, where his best work was done. He designed the cathedral at Bangor, Me., Christ church and the church of the Pilgrims in Brooklyn; and in New York, Trinity church, the Trinity building, Grace church, and St. Thomas' church, besides planning numerous private residences. For a time he was pres. of the American institute of architects.

UPOLU', one of the richest and most beautiful of the islands of the Pacific, belongs to the Samoan group, lying about 60 m. w. of Tutuila. It is 140 m. in circumference, and has 16,000 inhabitants. The island has been a mission station for many years, and the English consul was till 1875 the son of Mr. John Williams, the missionary, whose melancholy fate is well known. Many of the inhabitants are Christians. The chief harbor is Apia, a civilized-looking place, with many edifices on the European model.

UPPER DARBY, a township in Delaware co., Pa.; traversed by the Philadelphia, Wilmington, and Baltimore railroad; contains the villages of Fernwood and Landsdowne. Pop. '90, 4773.

UPPER SANDUSKY, village and co. seat of Wyandot co., O.; on the Sandusky river and the Columbus, Hocking Valley, and Toledo and the Pennsylvania Co.'s railroads; 60 miles s. of Toledo. It occupies part of the site of the home of the Wyandot Indians, and has an old Indian mission cemetery, electric lights, national and state banks, nearly a dozen churches, and foundries, machine shops, carriage factories, brewery, and casket, gas engine, plow point, and feed mill works. Pop. '90, 3572.

UPSALA or UPSAL, a district or län in Svealand, Sweden, situated on the gulf of Bothnia, 2051 sq. m.; pop. '95, 123,015. The surface is rugged and barren in the n. but has a fertile soil elsewhere; cattle are largely exported. Iron ore is found in large quantities. The best mines are those of Dannemora. Capital, Upsala.

UPSA'LA, an ancient and beautiful t. of Sweden, on the Fyrisa, a navigable stream 45 m. n.w. of Stockholm. The eastern part of the town stands on a wide and fertile plain; the w. part, containing the chief buildings, occupies a high range of ground looking over an apparently boundless plain to the n. and east. Upsala is the seat of an archbishop, who is the primate of the whole country. The great attraction is the cathedral, once a beautiful structure, and handsome still, though disfigured by restorations. It is in the Gothic style, built of brick, was founded in 1258, and completed 1435; is 370 ft. long by 128 broad, and 92 ft. high, and contains the tombs of Linnæus, and of Gustavus Vasa and several other Swedish kings. The university of Upsala—the chief institution of the kind in the country—founded in 1477, is attended by about 1700 students, taught by 122 professors and other teachers. The library contains 275,000 vols. and 12,000 MSS., several of which are very valuable. Pop. '95, 21,428, the mass of whom are dependent upon the university for their livelihood.—Two miles n. of the town is Old Upsala, now a village, which during the heathen period was the seat of the Odin worship, with a splendid temple and sacred grove, which have now disappeared. Also about 4 m. from Upsala are the famous Mora-stones, where in the middle ages the election and crowning of the Swedish kings took place.

UP-SAR-O-CA, or ABSAROKA. See CROWS.

UPSHUR, a co. in n.e. Texas; 520 sq. m.; pop. '90, 12,695, chiefly of American birth, includ. colored. Co. seat, Gilmer.

UPSHUR, a co. in central West Virginia, containing the head-waters of the Monongahela river; 350 sq. m.; pop. '90, 12,714, chiefly of American birth, with colored. Co. seat, Buckhannon.

UPSON, a co. in central Georgia, having the Flint river for its s. boundary; 321 sq. m.; pop. '90, 12,188, chiefly of American birth, includ. colored. Co. seat, Thomaston.

UPTON, a co. in w. Texas; created in 1887; unorganized, and attached to Midland co. for judicial purposes; 1140 sq. m.; pop. '90, 52.

UPTON, EMORY, b. N. Y., 1839; graduated at West Point, 1861. In the war of the secession he served as aid to Gen. Tyler, was wounded at Bull Run, and took part in the battles of South Mountain, Antietam, Fredericksburg, Chancellorsville, and Gettysburg. At Spottsylvania he was again wounded, but was present at the battle of Cold Harbor, the siege of Petersburg, the Shenandoah campaign, and elsewhere. He was promoted through the various grades, and at the end of the war had the brevet rank of maj.-gen. His treatise on *Infantry Tactics* was adopted in 1867. He d. 1881.

UR, a city in n. Mesopotamia, mentioned in the Bible, as the place from which Tarah, the father of Abraham, emigrated to Canaan. Its ruins, discovered by Rawlinson on the site of Mugheir, on the right banks of the Euphrates, contain the remnants of a large temple built in honor of the moon-god Sin, the tutelary deity of Ur.

U'RACHUS, THE, in the adult human subject, is a small fibrous cord formed by the obliteration of a tubular canal, which in the embryo runs from the apex of the bladder to the umbilical cord. In other mammals it remains open, and is continuous with one of the fetal membranes; and it has been found pervious in the human subject at birth.

U'RAL, a river of Russia, called *Rimna* by the ancients, later, *Jaik*, and since 1775 by its present name, rises in the southern section of the Ural mountains, near the e. frontier of the government of Orenburg. It flows s. through the district of Troitzk, past the town of Virchni-Uralsk, to its confluence with the Kisil; and in this region its course is over hilly meadows, and its current is very rapid, owing to its narrow and uneven bed. At the town of Orsk the river bends westward, and runs in that direction as far as the mouth of the river Tchagan, after which it flows directly s., and falls into the Caspian sea. It is deep enough for navigation; but owing to the scarcity of wood for ship-building, and the number of sandbanks that bar the river, no navigation can be carried on. This loss, however, is compensated by the fisheries of the river, which abounds in the most highly esteemed varieties of fish. The Ural has long served as the frontier separating Russia from the Kirghis steppes, and many forts have been erected, and a settlement of Cossacks — known as the Ural Cossacks — established along the river. The direct length of the Ural is estimated at 550 m.—with windings, 1040 miles. The principal affluents are the Kisil and Sakmara, on the right, and the Ore and Ilek on the left.

URAL MOUNTAINS (probably the Tartar word *ural*, belt), the *Hyperborean mountains*, or *Rhipæi montes*, of the ancients, form part of the boundary between Europe and Asia, and separate European Russia on the w. from Siberia on the east. The chain extends s. from the Kara sea, an arm of the Arctic ocean, to the middle course of the

Ural river, or from lat. 70° to that of 50° n., and is 1333 m. in length, with a breadth varying from 16 to 66 miles. Although the Ural mountains form really a single uninterrupted chain, geographers have agreed to consider them as divided into three sections—the northern, middle, and southern Ural. The northern Ural separates the basins of the rivers Petchora and Ob, is for the most part rocky, does not rise higher than 3,000 ft., and is commonly called *Poustoi* (empty), because it is extremely poor in ore. The middle Ural, commonly called *Roudnoi* (metalliferous), the principal seat of the mineral riches of the whole chain, comprises the highest peaks, as the Kanjakovski Kamen, rising to 5,000 ft.; but in some places the height is so insignificant, and the slope so gentle, that travelers can scarcely distinguish it from the lowlands. The southern Ural divides itself into three branches, two of which extend to the e. of the Ural river, and gradually disappear in the Uralo-Caspian deserts, while the third branch extends along the right—the western—bank of the Ural. The chain is composed chiefly of crystalline and metamorphic rocks, granite, gneiss, porphyry, chloritic, and micaceous schists. The Ural mountains, especially the middle and the n. part of the southern Ural (the governments of Perm and Orenburg), abound in mines of gold, platinum, copper, and iron. These mines, or *zavods*, are partly the property of the state, partly that of private individuals. Of the latter, the chief are the Nijni-Tagilsk, belonging to the Demidoff family; the Verchisetsk and Neviansk, belonging to the Takosleff family. The gold diggings occur on both slopes of the mountains, and gold is sometimes found in nuggets of considerable weight—the heaviest ever found in the chain being about 80 English lbs. in weight. In 1893, 26,352 lbs. of gold were extracted from the Ural mountains. The platinum found is chiefly obtained from the Nijni-Tagilsk mines. The richest copper ores in the Ural mountains are malachite and azurite; but the metal is extracted also from pyrites. Coal to the extent of 242,000 tons was extracted in 1894. The total amount of copper found in 1893 was 2789 tons. The amount of pig-iron extracted in 1895 was 542,000 tons. Among precious stones the most notable are the emerald, found on the eastern slope in the district of Ekaterinburg. Other precious stones are found, as the beryl, topaz, amethyst, and diamond, the last discovered in accordance with the prediction of Humboldt, but of small value. Malachite and jasper also occur. Rock-salt is abundant.

URALSK, a Russian t., capital of the province of the same name, stands on the right bank of the Ural, 150 m. s.s.e. of Samara. It was founded in 1622 by the Ural Cossacks, and was till 1775 known under the name of Jaitsk. A good trade is carried on—the principal articles being fish, isinglass, caviare, tallow, cattle, hides, and a variety of imported goods. Pop. '91, 27,036.

URANIA (i.e., "the heavenly muse") was a daughter of Zeus and Mnemosyne. She was regarded as the muse of astronomy, and was represented with a celestial globe, to which she points with a little staff.

URANIUM (sym. U, atomic weight–new system, 240–sp. gr. 18.33) is a very hard but moderately malleable metal, resembling nickel or iron in its luster and color; but in a finely comminuted state, occurring as a black powder. It is not oxidized by exposure to air or water at ordinary temperatures; but if heated in the air, it burns brilliantly, and is converted into oxide. It is a comparatively rare metal, which never occurs native; its sources being *pitch-blende*, which contains nearly 80 per cent of black oxide; *uranite*, which contains a hydrated double phosphate of lime and uranium; and *chalcolite*, which is a similar phosphate of copper and uranium. Uranium forms two principal oxides, a *dioxide*, UO_2, and a *trioxide*, UO_3. These can combine to form others. The dioxide is basic, while the trioxide is an acid-forming oxide. For the methods of preparing these oxides, the reader may consult any of the larger chemical text-books. The black oxide, U_2O_5, is of much value as a pigment for coloring porcelain; and compounds of the trioxide (or peroxide) with the earths are employed to communicate a peculiar yellow tint to glass. The salts of the dioxide have a green, and those of the trioxide a yellow color. None of them are of any special importance. The metal is extracted from pitch-blende; and its isolation in a pure form is due to Peligot in 1841; Klaproth's supposed metal (which he discovered in 1789) turning out to be the protoxide. The metal was not obtained in the compact form till 1856.

U'RANOS, or Cœlus, in mythology (a Greek word signifying heaven), son and husband of *Gæa* or *Terra*, the earth, and father of the Titans, Cyclopes, Hecatoncheirians, etc. He confined his children from their earliest infancy in Tartarus, but was overthrown and dethroned by Cronos, the youngest, at the instigation of Gæa. Out of the drops of his blood sprang the Gigantes, and Aphrodite rose out of the foam of the sea which gathered around him. He was succeeded on the throne of heaven by Saturn and Jupiter.

URANUS. See Planets.

URBAN, the name of eight popes, of whom the following deserve to be specially noticed.—Urban II., a Frenchman by birth, and originally a monk of Clugny, was elected in a council held at Terracina, in the year 1088, during the schismatical pontificate of the anti-pope Guibert, styled Clement III. Urban's name was Otho, and he had been bishop of Ostia. Soon after his election he resumed possession of Rome, the for-

tresses of which had been occupied by the anti-pope, whom he compelled to withdraw. Guibert, nevertheless, was still supported by his patron, Henry IV. of Germany, who had long been at feud with the papal see; and Urban, in concert with the celebrated countess Matilda, having formed a strong party in Italy, Henry once more led an army thither, and excited in Rome against the pope a party, whom he induced to recall Guibert—Urban establishing himself at Anagni. The revolt of Conrad, the eldest son of Henry, against his father, and his coronation as emperor at Milan in 1093, and still more the successful appeal of Henry's queen, Adelaide, turned the tide of affairs in Italy. A great council was held at Piacenza in 1095, in which the anti-pope and his adherents were excommunicated. In the same council the crusade was proclaimed; and in the following autumn, Urban, in a council held at Clermont, made the well-known appeal on the same subject, which called forth that enthusiasm which was destined to lead to the long series of efforts for the recovery of the Holy Land, which forms so striking a characteristic of mediæval history. In his later pontificate Urban pursued the same course, and, in the end, succeeded in driving Henry IV. out of Italy. The most important event of the last years of his pontificate was the holding of a council at Bari in 1098, in which many Greek bishops were present, and in which the addition of the words *filio que* to the creed was discussed. Thence he returned to Rome, of which he obtained full and undisturbed possession; and he died in the close of 1099, just at the time when the first crusade which he had organized terminated in the successful occupation of Jerusalem.—URBAN V. (originally William de Grimoard) is remarkable as practically the last of the popes who resided at Avignon, and the one by whom the papal seat was for a time re-transferred to Rome. He was a native of France, and had been abbot of St. Victor at Marseilles. On the death of Innocent VI. in 1362, he was elected at Avignon, where he continued to reside, sending his legate, cardinal Gil de Albornoz, to reduce the rebellious subjects of the papal see in Rome. After various alternations of peace and contest, Urban took the resolve of returning in person to the ancient seat of the papacy. He set out in 1367; and, landing at Corneto, proceeded first to Viterbo, and in the end to Rome, which he reached in Oct., 1367. He found the papal city in a condition all but ruinous, and the whole of Italy overrun by bands of mercenaries, and a prey to intestine divisions of the worst character. He endeavored, in concert with the queen of Naples, Joanna, in the following year, and of the emperor Charles IV., to repress these disorders, but with little success; and in 1370 he resolved once again to repeat the experiment of a withdrawal of the papal residence from Rome. He set out in September of that year; but only outlived his return to Avignon by a few weeks, and died in Dec., 1370, leaving the reputation of great personal piety, disinterestedness, and zeal for the interests of religion and morality.—URBAN VI. deserves a special notice as being the pope under whom the great western schism had its origin. His name was Bartolomeo Prignano, and at the time of his election he was archbishop of Bari. On the death of Gregory XI. (1378), who had finally returned from Avignon to Rome, and died in that city, Prignano was elected in a conclave held at Rome under circumstances of great excitement, owing to the apprehension, on the part of the populace, of an intention to elect a French pope, and again abandon Rome. The cardinals in the conclave numbered 16, of whom 12 were French, and 4 Italians. Prignano, although not a cardinal, was elected, April 8, 1378; and after the election had been made, the populace having broken into the hall, the cardinals dispersed; on the following day, however, they returned, confirmed the election, Prignano assuming the title of Urban VI., under which name he was crowned, April 18, in the presence of the 16 cardinals. In July of the same year the 12 French cardinals assembled at Anagni, and evoked the election of Urban, in which they declared that they had been acting under the fear of violence. To this course they are said to have been led by the rigor and the intemperate severity with which Urban was proceeding in the reforms of discipline, and especially of the simony and the irregular life of the clergy, including the cardinals themselves. They were joined by three of the Italian cardinals (one of them having died). On Sept. 20 they proceeded to elect the cardinal bishop of Cambray (born count of Geneva) pope, under the name of Clement VII. Clement took up his residence at Avignon. Urban, remained at Rome, where he appointed 26 new cardinals, and excommunicated Clement and his adherents. This conflict of claims was the origin of the Western Schism (see SCHISM, WESTERN). Urban was recognized as the lawful pope by one portion of the west, Clement by the other, and each maintained his claim by measures of the most extreme character. Urban especially, although his title seems to have been best founded, weakened his cause by his excessive violence. Having engaged in a dispute with Charles, king of Naples, whom he had himself crowned, he was besieged by that prince at Novara, whence he withdrew to Genoa, taking with him, as prisoners, the cardinals of his party with whom he had quarreled, and several of whom he is said to have put to death. In 1389, while he was on his way to Ferentino, he fell from his horse, and, having been conveyed to Rome, died from the injuries thus sustained in October of that year.—URBAN VIII. was the successor of Gregory XV. His family name was Maffeo Barberini. He was born at Florence in 1568; and after a long series of brilliant services both in the domestic administration and in foreign nunciatures, he was elected pope in Sept., 1623. In the difficult position of Roman affairs, as complicated between France, Austria, and Spain, in the war of the Valtellina, to which he succeeded on his

first election, he acquitted himself with much dexterity. His pontificate was also signalized by the acquisition to the holy see of the duchy of Urbino (q.v.) in 1626. Urban died in 1644. His memory has suffered through the imputation of nepotism; but his administration was, on the whole, vigorous and enlightened. He was the founder of the celebrated college of the Propaganda, and to him Rome is indebted for many public works, including large and important additions to the Vatican library. Some of the early stages of the Jansenist controversy (see JANSEN) fall within this pontificate.

URBANA, city and co. seat of Champaign co., Ill.; on the Cleveland, Cincinnati, Chicago, and St. Louis, the Illinois Central, and the Wabash railroads; 50 miles e.s.e. of Bloomington. It is the seat of the university of Illinois: contains five large modern public school buildings, Crystal Lake park, Deaconess home for orphans, co. poorhouse, public library, and the main shops of the C. C. C. and St. L. railroad; and has electric lights and street railroads, good sewerage and water supply, national and private banks, foundry and machine shop, planing mills, tile factories, and weekly newspaper. Pop. '90, 3511.

URBANA, city and co. seat of Champaign co., O.; on the Cleveland, Cincinnati, Chicago, and St. Louis, the Erie, and the Pittsburg, Cincinnati, Chicago, and St. Louis railroads; 40 miles w. by n. of Columbus. It is the seat of Urbana university (Swedenborgian), and has a high school, convent, public library, children's home, Soldiers' monument, electric lights, waterworks on the Holly system, national banks, about a dozen churches, railroad car works, straw-board works, woolen mills, broom factories, tannery, egg case factory, and daily and weekly newspapers. Pop. '90, 6510.

UR'BI ET OR'BI (Lat. to the city and the world), a form used in the publication of papal bulls, for the purpose of signifying their formal promulgation to the entire Catholic world, as well as to the city of Rome. By the canon law one of the conditions required in order that any new law shall be held to have force is "promulgation;" but a very celebrated controvery arose in the 17th c. as to the kind of promulgation which should be regarded as sufficient. In ancient times the practice of the popes had been to send copies of their bulls to the primates, metropolitans, and other ecclesiastical heads of the several churches, to be by them communicated to their suffragan bishops; but in progress of time the practice of publicly proclaiming or of posting up the decree in the Campo dei Fiori in Rome was substituted for this transmission; and decrees addressed URBI ET ORBI, and published in this way, were held to be thus sufficiently promulgated to the various churches, and to be thenceforth of full force. The French jurists of the 17th c. strenuously controverted this view.

UR'BINO, an old town in central Italy, province of Urbino e Pesaro, situated 25 m. s.w. of Pesaro, and between the rivers Metauro and Foglia. Its walls date from the 14th c.; it has a magnificent palace, once the residence of the dukes of Urbino, where was the famous library of the Della Rovere family, afterward removed to the Vatican. Another handsome palace is that of the Albini, belonging to an Albanian family escaped from the ferocity of the Turks and subsequently settled in Urbino, where they became rich and powerful and gave a pope to the church, who took the name of Clement XI. A university founded in 1564 is still in existence. Its manufactures and agriculture are flourishing. It is the birthplace of Raphael. Pop. '81, commune, 16,812. Urbino was a *municipium* under the Romans, and during the middle ages became the seat of a race of independent dukes, who existed up to 1626, when on the death of Francesco, the last duke, Urban VIII., took possession of the duchy as a vacant fief; and it continued to form part of the papal states till 1860, when it became part of the kingdom of Italy.

URCHIN, SEA. See ECHINIDÆ.

URE, ANDREW, M.D., a distinguished chemist, was born at Glasgow in 1778, educated at Glasgow university, subsequently prosecuted his medical studies at Edinburgh and returned to Glasgow, receiving the degree of M.D. in 1801. In 1802 he became professor of chemistry and natural philosophy in the Andersonian institution (see ANDERSON, JOHN), took an active part in the establishment (1809) of an observatory at Glasgow, and was appointed its first astronomer. In 1813 he made his appearance in the literary world as the author of a *Systematic Table of the Materia Medica*, which was followed in 1818 by *New Experimental Researches on Some of the Leading Doctrines of Caloric*, a memoir which, read before the royal society and printed in the *Philosophical Transactions*, brought Ure prominently into notice as a natural philosopher. Several papers on chemical subjects, the fruits of his accurate and extensive researches, followed. In 1821 appeared his *Dictionary of Chemistry;* in 1822 a paper *On the Ultimate Analysis of Animal and Vegetable Substances*, one of the earliest contributions to organic analysis, and a translation of Berthollet on *Dyeing;* and in 1829 a *System of Geology*, in which the hypothesis of a general flood was maintained. In 1830 Ure removed to London, and in 1834 was appointed analytical chemist to the board of customs. The products of his pen from this time assume more of a technological character, as the *Philosophy of Manufactures* (1835), *The Cotton Manufacture of Great Britain Compared with that of other Countries* (1836), and *Dictionary of Arts, Manufactures, and Mines* (1839). He died in 1857.

URE'A, $CO(NH_2)_2$, is an organic matter which derives its name from its having been originally discovered in the urine, of which it forms the most important and characteristic ingredient. It was until recently regarded as an organic base or alkaloid; but during the last few years it has been placed amongst the *amides*, a group of neutral, and for the most part crystallizable compounds, of the *ammonia type* (see TYPES, CHEMICAL), in which one of the three equivalents of hydrogen is replaced by the radical of an organic acid. For example, if R represent the radical, $\left.\begin{matrix}R\\H\\H\end{matrix}\right\}N$ represents the corresponding amide; and the character of the type is not affected by doubling the entire number of molecules, or changing it into $\left.\begin{matrix}R_2\\H_2\\H_2\end{matrix}\right\}N_2$. Now, if in this formula we substitute CO (carbonic oxide or carbonyl, as it is now often termed) for R_2, we obtain $\left.\begin{matrix}CO\\H_2\\H_2\end{matrix}\right\}N_2$, which is identical with $CO(NH_2)_2$, and possesses the advantage of showing the probable grouping of the elements in urea. Pure urea, which has been allowed to crystallize slowly, occurs in white, glistening, streaked, four-sided prisms; but when the crystallization is rapid or disturbed, it separates in small white silky needles. It is devoid of smell, has a coolish, bitter taste, like that of saltpeter (which it closely resembles in its external form), and is very slightly deliquescent. It is readily soluble in water and alcohol, but only slightly in ether. When heated to about 248° F. (120° C.), it fuses, evolves ammonia, and becomes completely decomposed. A solution of pure urea in distilled water may be kept for a long time, and may even be boiled without undergoing decomposition; but if heated in a close tube to about 284° F. (140° C.), each equivalent combines with four of water, and is converted into carbonate of ammonia, according to the formula—

$$\overbrace{CO(NH_2)_2}^{\text{Urea.}} + 2H_2O = \overbrace{(NH_4)_2CO_3}^{\text{Carbonate of Ammonia.}}$$

A similar change takes place slowly at ordinary temperatures in the urea contained in the urine, the mucus of the bladder acting as a ferment, and thus rendering urine ammoniacal after it has been kept for a few days.

The following are some of the most important of the compounds of urea: *Nitrate of urea*, $CO(NH_2)_2 \cdot HNO_3$, and *oxalate of urea*, $2CO(NH_2)_2 \cdot H_2C_2O_4$, are readily crystallizable salts, formed by the direct addition of the respective acids to a moderately strong solution of urea. As nitrate of urea requires eight parts of cold water, and is still more insoluble if an excess of free nitric acid is present, and the oxalate is more insoluble than the nitrate, while urea dissolves in its own weight of water, these salts may be employed to test for and approximately determine the quantity of urea. Among the compounds of urea with metallic oxides, those which it forms with the oxides of mercury are especially interesting, and have been completely examined by Liebig. A result of his researches is his celebrated method, which is now in universal use, of determined the amount of urea volumetrically.

Urea occurs as the main and characteristic ingredient of the urine of man and mammals, being most abundant in that of carnivorous, and least so in that of vegetable feeders. The average quantity excreted by the human subject is mentioned in the article URINE. It is also a constituent of the fluids of the eye, of the sweat, and (in minute quantity, of the blood, and of the liquor amnii (of the fetus). There can be no doubt that it is a final product of the regressive metamorphosis of the living tissues, or of their disintegration into simpler compounds, by means of which the final elimination of the worn-out structures is facilitated. Thus, we find that urea may be obtained by oxidizing agents from uric acid, creatine, allantoine, etc., in the laboratory, and there is every reason to suppose that similar changes may occur in the system. Whether, when an excess of food is taken, a portion of it may be formed in the blood into urea, and then at once separated without ever having entered into the structure of the higher tissues, is a point which is scarcely decided.

Until the discovery by Liebig and Wöhler of the artificial formation of urea, its only source was the urine, from which, after evoporation, the nitrate was separated, purified by animal charcoal, and the urea liberated by the addition of carbonate of baryta, and finally extracted by alcohol, from which it was allowed to crystallize. It is now known that there are many different ways of forming it, as (1) by the action of chlorocarbonic oxide or phosgene gas, $COCl_2$, on dry ammonia; or (2) by heating a mixture of ethyl carbonate, $(C_2H_5)_2CO_3$, and an alcoholic solution of ammonia to about 356° F. (180° C.), in a closed tube (both of which methods show that urea is truly the *amide of carbonic acid*); but the best practical method is essentially the original one of mixing watery solutions of potassium cyanate and ammonium sulphate, and evaporating the solution, which leaves a residue consisting of urea and potassium sulphate, the former of which may be extracted by alcohol.

URE'AS, THE COMPOUND, include a large class of singular organic bodies, for the knowledge of which chemistry is mainly indebted to Prof. Hofmann. Compounds of this kind are most readily formed by the action of cyanic acid on the amines or amidogen

bases of the alcohol radicals, such as methylamine, ethylamine, etc. (the methylia, etc., of Miller and other chemists), instead of on ammonias. Thus, while ordinary urea is formed by the action of this acid on ammonia, methyl-urea, ethyl-urea, etc., are formed by its action on methylamine, ethylamine, etc., as shown in the following formula:

Ammonia.		Cyanic Acid.		Urea.
NH_3	+	$HNCO$	=	$CO(NH_2)_2$
Methylamine.		**Cyanic Acid.**		**Methyl-urea.**
$CH_3 \cdot NH_2$	+	$HNCO$	=	$CO(NH_2)(NHCH_3)$
Ethylamine.		**Cyanic Acid.**		**Ethyl-urea.**
$C_2H_5 \cdot NH_2$	+	$HNCO$	=	$CO(NH_2)(NHC_2H_5)$

These are the simplest forms of these compounds ; among the more complicated ones are ethyl-methyl-urea, $CO(NH_2)(N \cdot CH_3 \cdot C_2H_5)$, phenyl-ethyl-urea, $CO(NH_2)(N \cdot C_2H_5 \cdot C_6H_5)$, etc. All these compound ureas combine like ordinary urea with acids, and form crystallizable salts.

URE'DO, a genus of minute parasitic fungi, of the order *coniomycetes*. The original genus uredo has been divided into many genera, forming a group called *uredineæ*, which contains a multitude of species, parasitic on phanerogamous plants of almost every natural order, and in all parts of the world, at the equator and at the extreme limits of arctic and antarctic vegetation. Different plants have their own peculiar parasites of this kind, or the same *uredineæ* are at least confined to plants nearly allied. A few species occur on ferns, but not very frequently. Every external part of plants, except the roots, is liable to be infested with these fungi, and some of them attack the inner tissues, their spores at length breaking through the outer strata of cells. Submerged parts of plants are never affected by them, for fungi dislike water; but the floating portions of aquatic plants are not exempt; and in all cases a moist atmosphere seems to be favorable to their development. Rank luxuriance of growth is often attended by their appearance. A plant once attacked is afterward subject, if perennial, to the same parasite, even if removed to another situation. There is reason to believe, from experiments made by Fée, that the spores of the *uredineæ* are taken up by the roots of plants from the soil, and find their way with the sap to the place proper for their growth. See Brand, Bunt, Mildew, Rust, and Smut.

URE'NA, a genus of herbaceous plants of the natural order *malvaceæ*. The bark is very fibrous; and the fiber of *U. lobata* and *U. sinuata*, weeds common in most parts of India, is used as a substitute for flax. It is strong, and tolerably fine.

U'RETERS (Gr. *ouron*, urine, and *tērein*, to keep), the canal by which the urine is conveyed from the pelvis of the kidney (see Kidneys) on either side to the base of the bladder. Each ureter is about 18 in. in length, and enters the bladder in so slanting a direction as to prevent regurgitation.

When a concretion is formed in the kidney, the ordinary and most favorable event is that it should descend through the ureter to the bladder. The passage of a stone through this tube gives rise to a series of violent symptoms, which are thus summed up by Druitt: "The patient complains of sudden and most severe pain, first in the loins and groin, subsequently in the testes (in the male) under the thigh. The testes are also retracted spasmodically. At the same time there are violent sickness, faintness, and collapse, which may last two or three days, and are only relieved when the stone reaches the bladder."—*The Surgeon's Vade-mecum*, 8th ed., p. 594. The treatment consists in the warm bath, and the inhalation of chloroform, or opium in large doses (both of which serve to allay spasm and deaden pain), the free use of diluents to wash down the concretion, and if the sickness is very severe, an occasional tumbler of hot water containing half a tea-spoonful of carbonate of soda.

URE'THRA is the term given in anatomy to the canal by which the urine is discharged from the bladder. Its most common affections are the special inflammatory condition of its mucous lining, known as gonorrhœa (q.v.), and stricture (q.v.).

URFA, or Orfa, the modern name of Edessa (q.v.).

URGA, a town, capital of northern Mongolia, on the river Tola, at the height of 4370 ft. above sea-level, 350 m. s.e. of Irkutsk. In one of the suburbs of the town is a college of Mongolian priests, which is the seat of the Lama of the Mongols. See Lamaism. The college or convent covers an extensive area, and includes the dwellings of the priests. The population is made up of a colony of Chinese and about 25,000 Mongols, 10,000 of whom are priests. Each family educates one of its children to be a priest. The buildings of the college have of themselves more the appearance of a town than the other quarters of Urga. The number of the inhabitants is estimated at 30,000.

U'RI, one of the Waldstätten or forest cantons of Switzerland, forms part of the hill country (see Switzerland) which surrounds the lake of Lucerne, and is bounded on the w. by the cantons of Unterwalden, Bern, and Valais. It has an area of 415 sq. m.

and its pop. in '70 was 16,107; in '94, 17,249. It consists of one valley, that of the Reuss, about 30 m. in length, and inclosed on all sides by lofty mountain chains, which also include the south-eastern bay or reach of the lake into which the river falls. A great high-road passes through the valley, and terminates on the south at the St. Gothard pass which connects Uri with Ticino, and forms part of one of the great routes into Italy. It is traversed by the St. Gothard railroad. Uri is almost entirely pastoral, and its products are those of its herds and flocks. Goats are very numerous. In the low grounds, there are a few fields of corn and potatoes, and gardens and orchards, but even this cultivation is limited. The population speak a Swiss-German dialect and are Roman Catholic. Uri sends one member to the national council. It joined with Unterwalden and Schwyz in the 13th century to form the Swiss confederation. It was the scene of various conflicts between the French, Russians, and Austrians in 1799, and became a canton in 1803. Altorf, the capital, is a small town, with about 3000 inhabitants. A fountain, surrounded by stone statues of Tell (q.v.) and his son, marks, according to tradition, the spot where the former took his aim, and another that where the boy stood with the apple on his head.

URI, BAY OF, or **LAKE OF**, or **URNER SEE**, in Switzerland, the s.e. arm of Lucerne lake with a length of about 8 m.

U'RIC or LITHIC **ACID**, $C_5H_4N_4O_3$, derives its names from its being a constituent of urine and of urinary calculi respectively. In a state of purity, it occurs in the form of a loose white powder or scales consisting of minute crystals, devoid of smell or taste, only very slightly soluble in water (1 part requiring about 15,000 parts of cold, and 1800 of boiling water), and quite insoluble in alcohol and ether. This acid is, however, soluble without decomposition in strong sulphuric acid, and it may be thrown down from this solution by the addition of water. It is also soluble in the carbonates, borates, phosphates, lactates, and acetates of the alkalies, extracting from these salts a part of their base, with which it forms acid urates. Litmus paper is reddened by its moist crystals, or by a hot watery solution. This acid is not volatile, and by dry distillation is decomposed into carbonate of ammonia, urea, cyanuric acid, hydrocyanic acid, etc. On heating a mixture of uric acid and water, with gradual additions of peroxide of lead, which is a strong oxidizing agent, the uric acid becomes oxidized, takes up water, and becomes converted into urea, allantoine, and oxalic acid, as is shown by the equation:

$$\overbrace{2C_5H_4N_4O_3}^{\text{Uric Acid.}} + \overset{\text{Oxygen.}}{O_2} + \overset{\text{Water.}}{5H_2O} = \overbrace{2CO(NH_2)_2}^{\text{Urea.}} + \overbrace{C_4H_6N_4O_3}^{\text{Allantoine.}} + \overbrace{2H_2C_2O_4}^{\text{Oxalic Acid.}},$$

the lead being left in combination with the oxalic acid. This is a most important result in its physiological bearing, since it shows how uric acid is a probable stage toward the formation of urea, and as explaining a probable source of the oxalic acid, which is often present in the urine in cases of deficient respiration and aeration; and this view is confirmed by the experiment of introducing uric acid into the stomach or veins of an animal, when the presence of oxalate of lime, and the augmentation of urea, are very soon perceived in the urine.

Uric acid is a very weak bibasic acid, forming with bases two series of salts, the neutral and the acid, of which the former are the more soluble. Among the most important of these urates are—(1) *neutral urate of potash*, which occurs in the form of a white granular crystalline powder, difficult of solution in water (requiring 44 parts of cold, and 35 of boiling water), but readily soluble in an excess of potash, from which solution carbonic acid throws down the *acid urate of potash* in the form of a transparent jelly, which sometimes falls in the form of a powder; (2) two *urates of soda*, each of which is less soluble than the corresponding potash salt; (3) *acid urate of ammonia;* (4) *acid urate of magnesia;* (5) two *urates of lime;* and (6) *urate of lithia*, which is more soluble than any other urate; and hence lithia water is an important therapeutic agent in converting uric acid and the more insoluble urates into a soluble salt in the living body.

Uric acid is widely distributed throughout the animal organism. It occurs not only in the urine of man and carnivorous animals, but is the chief constituent (either free or in combination) of many calculi occurring in the kidneys or bladder, and of numerous urinary sediments. The urinary secretion of birds and reptiles consists almost entirely of urates, which are also found in the excrements of caterpillars, butterflies, beetles, etc., and of many mollusks. Moreover, in very minute quantities, it occurs as a urate in healthy blood, in which fluid it has been found in excess in gout and Bright's disease, and is a constituent of the aqueous extract of the spleen, liver, lungs, pancreas, and brain. The *chalk-stones* occurring about the smaller joints, and in the lobes of the ear of gouty patients, consist mainly of urate of soda.

The best and most ready mode of obtaining pure uric acid is from the semi solid urine of serpents, which consists almost entirely of urates. The mass is boiled with

potash, which expels any ammonia that is present, and a stream of carbonic acid is then passed through the strained potash solution, which throws down acid urate of potash. This precipitate is dissolved in water, and decomposed by hydrochloric acid, which throws down the uric acid in minute crystals. The form in which this acid crystallizes is liable to great variations. Sometimes we have flat tablets resembling whetstones, or sections with a double knife through biconvex lenses; at other times, more or less perfect rhombic tablets, and sometimes hexagonal plates, barrel-shaped prisms, and toothed crystals. If there is any doubt as to the nature of the crystals, they should be dissolved (under the microscope) in a little potash solution, and a drop of hydrochloric acid then added, when sufficiently characteristic forms are sure to appear.

The marvelous researches of Wöhler and Liebig on the products of decomposition of uric acid by nitric acid, constitute an epoch in organic chemistry. The most important products, some of which are obtained directly, and others indirectly, are: (1.) *alloxan*, $C_4H_2N_2O_4$ (which, under the influence of various reagents, yields *alloxanic acid*, *mexoxalic acid*, *mykomelinic acid*, and *dialuric acid*); (2) *parabanic acid*, $C_3H_2N_2O_3$ (which yields *oxaluric acid*); (3) *alloxantine*, $C_8H_4N_4O_7 + 3H_2O$ (which yields *alloxan*, *allituric acid*, *uramel*, *thionuric acid*, *oxaluric acid*, and *murexide*); (4) *murexide*, $C_8H_4N_5O_6 \cdot NH_4 + H_2O$ (which yields *murexan*, or *uramel*, and *alloxan*); and (5) *urea*, which breaks up into carbonic acid and ammonia. Moreover, by boiling oxaluric acid with water it is decomposed into oxalic acid and urea. Of these substances, we shall only notice *murexide*, which has two special claims to notice. It is used as a pigment in dyeing, being probably the old *Tyrian purple* (see MUREXIDE), and it affords a ready test for a mere trace of uric acid. In using it for the latter purpose, the substance supposed to contain uric acid is heated on a slip of glass with a drop of nitric acid, and carefully evaporated to dryness. If uric acid is present, the residue has a red color, which is converted by vapor of ammonia into a fine crimson, and the addition of a drop of a solution of potash develops a splendid purple tint, which disappears on the application of heat.

Uric acid must be regarded, like urea, as a product of the disintegration of the tissues; and it is far from improbable that all the urea which is secreted may have pre-existed in the form of uric acid—a view which is supported by the fact, that whatever (like excessive exercise or water-drinking) increases the amount of urea, decreases that of uric acid, and *vice versâ*. See URINE.

URICO'NIUM, an ancient Roman city of Britain, the site of which is about 4 m. to the e. of Shrewsbury, and is partly occupied by the village of Wroxeter. The original name seems to have been *Viroconium*, which was changed in the later Roman-British period to Uriconium. It is mentioned by Ptolemy as existing in the beginning of the 2d c. A.D. The remains of the city show it to have been a place of much importance. The wall can still be traced near the banks of the Severn, forming an irregular oval rather more than 3 m. in circumference. It appears that one of the principal streets of the city occupied the line of the *Watling street road*. The remains of Uriconium have recently been explored by an association formed for the purpose at Shrewsbury, and many curious relics of antiquity have been discovered, throwing great light on Roman civilization in Britain. The human remains found in the excavations which have been made, affording proof of death by violence or by suffocation, show that the city did not slowly decay, but was sacked and burned by enemies, which probably took place about the 5th century. Of this, however, there is no certain historic record. The ruins seem to have remained with little change, except the gradual process of decay, till about the 12th c., when they were used as materials for other buildings. Some of the churches of the neighborhood were built of the old Roman bricks. The walls of buildings are now found, perfect as far as the previous accumulation of earth rendered it difficult to remove the bricks of which they were constructed. The most remarkable relic of antiquity in Uriconium is the *old wall*, a great mass of Roman masonry, which appears to have been the side of a great edifice, remains of Mosaic pavements having been found near it, and apparently connected with it. The edifice to which the old wall belonged is supposed to have occupied a corner at the junction of two principal streets. The excavations which have been made, however, leave it very difficult to explain the character and purpose of the remains discovered. Several inscriptions have been found at Uriconium, but none of great interest. A museum has been formed at Shrewsbury, in which most of the antiquities from this spot are collected. Hair-pins, combs, and rings are particularly numerous among them.

U'RIM AND THUM'MIM (Heb.), a mysterious contrivance in or on the high-priest's breast-plate, either consisting of the four rows of precious stones upon which the names of the 12 tribes were engraved, or of two images personifying—most probably—"Truth" and "Revelation." Luther's translation, "light and truth," has no more real foundation than that of the LXX. and the Vulgate, which is "utterance and truth." To this translation, the fact of the picture of "Truth" (Aletheia)—in sapphire or other precious stones—being suspended from the Egyptian high-priest's breast, had probably given rise. The etymology of the two words, which, derived from Arabic roots, would indicate "brilliant amulet," "perfect light," etc., is in reality no more satisfactory than the account of the manner in which the contrivance was used for oracular purposes, or of the time when, in reality, it ceased to act. It is never mentioned after Solomon's time.

U'RINARY SEDIMENTS is a general term which includes all those substances which occur in a non-dissolved state in the urine. Most of these sediments are not formed until after the urine has been discharged and has cooled; some, however, are formed in the urinary organs, and under favoring conditions may give rise to urinary concretions. Hence it is a point of importance to ascertain whether a sediment occurring in a specimen of fresh urine has been formed before or after its discharge.

The chemical and microscopical character of these sediments has a double bearing on the detection of disease: (1.) "From the investigation of these sediments," says professor Vogel, "we can draw sure conclusions regarding special changes that are going on in the general nutrition of the body. They show us that an excessive quantity of certain substances (as for example, uric, hippuric, or oxalic acid) is being discharged with the urine, and has therefore been produced in the body; and we thus often obtain at a glance information of great importance, which could otherwise only be procured by a tedious process; and (2) they point out to us certain local diseases of the urinary system. Thus, from a sediment containing pus, we infer that suppuration in going on in some part of that system; and the presence of cylindrical casts or tubes in the sediment informs us of certain morbid changes in the structure of the kidneys; and if the ordinary symptoms reveal the presence of stone in the bladder, we can ascertain its probable nature from the character of the sediment or gravel."

The mode of formation of morbid sediments is well illustrated by a sketch of the changes which healthy urine undergoes after prolonged exposure to the air. In the course of two or three days, the acidity of the urine is found to have increased, and this condition of *acid fermentation* will frequently continue for some weeks, giving rise to the deposition of (1) free uric acid; (2) acid urates (chiefly urate of soda); and (3) oxalate of lime. In a few weeks, or often much sooner, the urea becomes alkaline, or *alkaline fermentation* is established, in consequence of the urea being converted into carbonate of ammonia. The urine now becomes paler, while the red or yellow crystals of uric acid are replaced by white amorphous granules and colorless refracting prismatic crystals. In other words, the former precipitate is replaced by (1) phosphate of ammonia and magnesia (commonly known as triple phosphate); (2) phosphate of lime; and (3) urate of ammonia. In certain forms of disease, these changes take place much more rapidly, and the second change—the alkaline fermentation—may occur without a pre-existing acid fermentation, and even within the bladder. In addition to the above-named substances, which arise from the decomposition of healthy urine, others occur in various morbid conditions of the system; and we may divide the urinary sediments generally into the two great groups of (1) the unorganized and (2) the organized deposits. The unorganized sediments include uric acid, the urates (chiefly urate of soda), hippuric acid, oxalate of lime, earthy phosphate (viz., phosphate of lime, and triple phosphate), crystine, xanthine, pypoxanthine (formerly known as guanine), and tyosine; while the organized sediments include mucus and epithelial scales, blood corpuscles, pus corpuscles, cancerous and tubercular matter, fibrinous casts of the tubes of the kidney, spermatozoa, fungi, infusoria, etc. Of the unorganized sediments uric acid, the urates (excepting urate of ammonia), hippuric acid, and crystine occur only in acid urine, and urate of ammonia, triple phosphate and phosphate of lime, in alkaline or neutral urine. Oxalate of lime and the organized sediments occur both in acid and alkaline urine; but alkaline urine is the more natural *habitat* for fungi and infusoria. It is comparatively seldom that a sediment consists of a simple ingredient. Most of our knowledge on this important subject is due to the labors of English physicians, among whom the names of Prout and Golding Bird are especially deserving of notice. For details regarding the mode of treatment suitable in the most important of the sediments, we may refer to the articles Lithic Acid Diathesis, Oxaluria, and Phosphatic Diathesis, in this work, and to Dr. G. Bird's *Urinary Deposits and their Treatment;* while for details regarding their chemical and microscopical characters, Neubauer and Vogel, *On the Urine,* translated under the auspices of the New Sydenham society, may be consulted.

U'RINE is the fluid which is secreted or separated by the kidneys from the blood, and it is the principal means of removing the worn-out tissues, especially the nitrogenous and saline matters, from the system. It is a very complex fluid, and its composition varies considerably in different classes of animals, and mainly in accordance with the nature of the food.

Healthy human urine, when freshly discharged, is a clear fluid of a bright amber color, a bitter, saltish taste, and a peculiar aromatic odor. Its normal reaction is acid, and its specific gravity ranges from 1.015 to 1.025. From a table published in Day's *Physiological Chemistry,* p. 352, it appears that an adult man of ordinary weight (about eleven stones) secretes in 24 hours about 52 fluid ounces (or rather more than two pints and a half) of urine, the range extending from 40 to 70 ounces; and that these 52 ounces yield, on evaporation, 935 grains of solid constituents, the remainder being water, which is expelled by heat. Of these 935 grains, 520 (or more than an ounce) are composed of urea (q.v.), and 266 of chloride of sodium (or common salt); while the remaining 149 grains are made up of uric acid (q.v.), hippuric acid (q.v.), sulphuric acid, 32 grains; phosphoric acid, 54 grains; earthy phosphates, 15 grains; ammonia (in the form of hydrochlorate), 11 grains; with smaller quantities (in most cases mere traces) of creatinine

(q.v.) and creatine (q.v.), xanthine, hypoxanthine, coloring matters, mucus (from the walls of the bladder), iron, silica, and fluorine. The fluid also holds an undetermined quantity of gases (carbonic acid and a little nitrogen) in solution. The most characteristic and important of these ingredients is the *urea*, the daily excretion of which is modified by various circumstances. On a purely animal diet, Lehmann found that he secreted two-fifths more urea than when he was living on an ordinary mixed diet; while on a mixed diet there was secreted almost one-third more than on a purely vegetable diet; while finally, on a non-nitrogenous diet, the amount of urea was less than half the quantity secreted during a mixed diet. The free use of common salt increases the daily excretion of urea, in consequence, doubtless, of its augmenting the rapidity of the destructive action always going on in all the tissues; while alcohol, tea, coffee, and tobacco (whether smoked or chewed) diminish the daily quantity. The only medicine which increases its quantity to any marked degree is *liquor potassæ*. The daily quantity is increased in many diseases (typhoid fever and many other acute diseases, especially inflammation of the membranes of the brain), while in Bright's disease and a few other disorders, it is diminished. The daily amount of excreted *uric acid*, like that of urea, varies with the nature of the food. Thus, for instance, Prof. Haughton found that the mean daily quantity of uric acid excreted by meat-eaters and wine-drinkers was 4.5 grains, while vegetarians yielded an average of only 1.48 grains, part of which, moreover, was hippuric acid. As an excess of uric acid is likely to give rise to gravel or stone, it should be generally known that the free ingestion of water diminishes its excretion, while at the same time it increases the amount of urea, into which the uric acid is probably transformed by oxidation. The daily amount is diminished by strong bodily exercise, and increased by repose; the reverse of what holds good in relation to the urea. The amount is increased when the digestive functions are disturbed, as after the use of indigestible food or excess of alcoholic drinks; in those conditions of the system which are associated with much disturbance of the functions of respiration and circulation; and in disorders accompanied with severe febrile symptoms, such as acute rheumatism. Its entire absence seems compatible with perfect health. With regard to *hippuric* acid there has been much discussion, not only as to the quantity in which it occurs, but as to whether it actually exists in healthy urine. Thus, Weissman, a German chemist, finds that on a mixed diet he secreted more than 40 grains of this acid daily, and on a purely animal diet, only 12 grains. Duchek and Höfle deny that it is a constant ingredient of healthy human urine; and Prof. Haughton only met with it once in the urine of ten men. Dr. Bence Jones, a very trustworthy chemist, found that a man, A, weighing 152 lbs., and a man, B, weighing 202 lbs., living on a mixed diet, excreted daily, on an average, 4.9 and 6.5 grains of hippuric acid, the corresponding quantities of uric acid being 7.7 and 12.6 grains. In cases of jaundice, no traces of hippuric acid are present, even after the administration of benzoic acid,* which is usually converted in the system into hippuric acid. Hence it may be inferred that a healthy condition of the urine is essential to the formation of this acid in the system. Nothing is known with certainty regarding the diseases in which this acid is secreted to excess. The only other characteristic ingredient of the urine is its *coloring matter*. Prof. Harley believes that he has isolated the normal urine-pigment, to which he applies the term *urohæmatin;* and from its always containing iron, and on other grounds, he regards it as modified hæmatin or blood-pigment. Mr. Schunck has also shown that indigo-blue, in very small quantity, is almost always present.†

It has been already stated that fresh healthy human urine presents an acid reaction. This reaction mainly depends upon the presence of acid phosphates of the alkalies and earths, although the presence of free acids, such as free hippuric, or possibly lactic acid (which, however, is not a normal ingredient), may occasionally contribute to increase the acidity. To determine the acidity of the collective 24 hours' urine, we take a solution of oxalic acid of known strength, and ascertain the relative quantities of a solution (of definite strength) of caustic soda which are required to perfectly neutralize equal volumes of the urine and of the oxalic acid solution. In this way it is found that the total quantity of free acid in the daily urine of a healthy man corresponds in neutralizing power to about 36 grains of oxalic acid. The degree of acidity varies in different parts of the day. Dr. Bence Jones mooted the idea (in 1849), that the respective acidities of the secretions of the kidneys and stomach stood in an inverse relation, and that urine may even become alkaline during stomachal digestion. Dr. Roberts of Manchester, who has subsequently investigated this point, finds that the effect of a meal on the acidity of the urine begins to show itself in the second hour afterward, is most marked during the next three hours, and disappears by the end of the sixth hour, the fluid being almost always positively alkaline during the third and fourth hours. Independently of this periodic alkalinity, the urine may be made alkaline at will by the administration of caustic alkalies, their carbonates or their salts, with organic acids (citrates, tartrates, etc.; such

* Duchek found that when 1 gramme (15.44 grains) of benzoic acid was taken, 0.714 of a gramme of hippuric acid was excreted; when 2 grammes were taken, 1.857 grammes of hippuric acid, and 0.421 of benzoic acid, were excreted; and the ingestion of 4 grammes was followed by the excretion of 1.714 of hippuric acid and 2.500 of benzoic acid. Hence the limit of conversion had been already exceeded.

† He failed to detect it in only one case out of forty. He only succeeded in obtaining *one grain* by working for several weeks on the urine of two persons. The urine of the horse and cow yielded comparatively large quantities.

as occur in many fruits); while after the administration of acids the acidity is much increased.

In disease, the urine may either contain only its ordinary ingredients in abnormal proportions, or it may contain ingredients not occurring in the healthy fluid. Thus there may be an excess or diminution of urea, an excess of uric acid, a diminution of chloride of sodium, which, in cases of inflammation of the lungs, may fall from 266 grains to a mere trace, and, by its daily diminution or augmentation, tells with certainty whether the disease is gaining or losing ground; an excess of coloring matter or of mucus, etc.; or, on the other hand, the urine may contain albumen, sugar, oxalic acid (in combination with lime), fat, leucine and tyrosine, bile-pigment, biliary acids, etc. The subject of "the urine in disease," is, however, so wide a one that we must refer our readers for details to Lehmann's *Physiological Chemistry*, 3 vols. (translated for the Cavendish society), to Dr. Parkes's excellent work on *The Urine*, and to the various works of Dr. Beale.

We conclude with a few remarks on the urine of mammals generally. The urine of the carnivora is clear, of a light-yellow color, a disagreeable odor, a nauseous taste, and an acid reaction. It contains much urea, little pigment, and little or no uric acid. The urine of the herbivora is turbid, yellow, of a less unpleasant odor, and alkaline. In addition to urea, it contains hippuric (but no uric) acid, alkaline lactates, carbonates of potash and of the earths, oxalate of lime, and a small quantity of phosphates. By reversing the natural food of these classes, we reverse the characters of the urine.

The urine in many forms of disease becomes turbid on cooling, and soon deposits a sediment; and even healthy urine, after a few days's exposure to the air, loses its clearness, and throws down a deposit of mucus and various kinds of crystals. The investigation of the nature of the deposits thrown down by comparatively fresh urine in disease, is noticed in the article URINARY SEDIMENTS.

URINE, INCONTINENCE OF, or ENEURESIS, is a troublesome affection, far more common in childhood than in more advanced life. The child may have no bad symptom of any kind that can be detected, but it is in the constant habit of discharging its urine in bed during sleep. It sometimes wakes with a consciousness that it is performing the act, but most commonly it is not disturbed. The act may take place once, or several times, during the night, and sometimes there is an interval of a night, but seldom more. The child may often be broken off this unpleasant habit by proper domestic management, as withholding any excess of fluids before going to bed, and by waking it, and making it discharge the contents of the bladder at the time when the elder members of the family retire to bed. When such means as these fail, recourse must be had to medical advice. Blisters to the sacrum, which prevent the patient from lying flat on the back, and consequently prevent the urine from gravitating toward the most irritable part of the bladder, are often useful; and cold douches to the spine, combined with the internal use of chalybeates, are frequently serviceable. The most certain remedy, however, is extract of belladonna, given at first, according to the age of the patient, in doses varying from $\frac{1}{16}$ to $\frac{1}{8}$ of a grain, twice daily, and increasing it, if required, till it gives rise to marked constitutional disturbance.

The various forms of mechanical pressure that have been suggested, with the view of preventing the passage of the urine, cannot be too strongly reprobated.

URNER SEE. See URI, BAY OF.

UR'QUHART, DAVID, b. Scotland, 1805; educated at St. John's college. In 1835 he was secretary of legation at Constantinople, but opposed Palmerston's eastern policy and therefore resigned his position. He sat in parliament as conservative member for Stafford, 1847–52. He is the author of *Turkey and its Resources*, *The Mystery of the Danube*, and other books bearing on the eastern question. **He d. 1877.**

URQUIZA, JUSTE JOSÉ DE, 1800–70; b. Entre Rios; of Spanish and Indian descent. In the La Plata war he was general of division under Rosas. In 1840 he led the Uruguay invasion, and in 1845 won the victory of India Muerta. In 1857, then being governor of Entre Rios, he became involved in quarrels with Rosas, head of the Argentine confederation, raised an army from Brazil, Paraguay, and Uruguay, routed Rosas at Santos Luzares, and made himself dictator of the Argentine republic. From 1854 until his death he was engaged in war with Buenos Ayres, and was generally unsuccessful. He was assassinated April 11, 1870.

URSA MA'JOR, "the Greater Bear," and URSA MINOR, "the Lesser Bear," are two celebrated constellations in the northern hemisphere of the heavens. *Ursa Major* was distinguished as early as the time of Homer by the names *Arktos*, "the Bear," and *Hamaxa*, "the Wagon," the vivid imagination of the Greeks discovering a fanciful resemblance between these objects and the group of brilliant stars in this constellation. The Roman name Ursa was a translation of the Greek *Arktos;* the Romans also called its seven bright stars the *Septemtriones*, "the seven plowing oxen," whence the adjective *septentrionalis* came to signify north. The common names throughout Europe for these seven stars are "the Plow," "Charles's Wain," "the Wagon"—evidently derived from the classical epithets above mentioned. When the constellation of Ursa Minor was generally recognized, the adjective *megale*, "great," was annexed by the Greeks, and *major*, "greater," by the Romans, to the name of this constellation. The remarkable

group of stars in the hinder part of the Great Bear being within 40° of the north pole, never sinks below the horizon of any place in a higher n. latitude than 40°, a peculiarity alluded to by Ovid in his *Metamorphoses*. It contains a considerable number of stars, 17 of which are easily visible by the naked eye; but of these, only one (α) is of the first magnitude, two (β and γ) of the second, and eight (among whom are δ, ε, ζ, and η) of the third. Of the seven stars constituting "the Plow," α and β are known as "the Pointers," from their use in detecting the *pole-star* (q.v.). A line drawn from the pole-star through η of the Great Bear, and produced its own length, passes close to the star Arcturus of the first magnitude.—*Ursa Minor* is less prominent in the heavens. It was also *Arktos* and *Hamaxa* among the Greeks, and *Arctus* and *Ursa* among the Romans, from the close resemblance of its chief star-group to that of Ursa Major; but was, besides, distinctively denominated *Kynosoura* or *Kynosouris*, and *Cynosura*, "the Dog's Tail," from the circular sweep, resembling the curl of a dog's tail, formed by three of the stars in it. The star α in the extremity of the tail of the Little Bear, at present the pole-star (q.v.), is the brightest in the constellation, though only of the third magnitude.

According to the later mythical stories of the Greeks, Ursa Major was the metamorphosis of Callisto, one of Diana's nymphs, who, having violated her vow, and being transformed by her indignant mistress into a bear, was slain by her son Arcas, and afterward transferred to the heavens as a constellation by Jupiter; Arcas being at the same time metamorphosed into Boötes, the Arktophylax, "Bear-warden," of the Greeks. According to the other but less common legend, which represents the seven stars of Ursa Major as the oxen of Icarius, Arktophylax became *Boötes*, "the Ox-driver."

URSIDÆ. See Bear.

URSON, *Erythizon dorsatum*, a quadruped nearly allied to the porcupine, and often called the Canada porcupine. The genus *erythizon* differs from *hystrix* (porcupine) in the flatter head, the shorter and not convex muzzle, the longer tail, and in having the quills short and half hidden in the hair. The urson is about the size of a small hare. It is found as far s. as Virginia and Kentucky, and as far n. as lat. 67°. Its quills are dyed by the Indian women, and worked into ornamental articles of various kinds.

URSULA, St., a celebrated saint and martyr of the Roman calendar, especially honored in Germany, and particularly at Cologne, which is the reputed place of her martyrdom. The legend substantially, in its present form, can be traced as far back as the end of the 11th or beginning of the 12th c., as it is found in the revised edition of the Chronicle of Sigebert of Gemblours (Pertz, *Rerum Germanicarum Scriptores*, viii. 310), which was made between 1106 and 1111. According to this writer, Ursula was the daughter of the British king Deonatus; and on account of her distinguished beauty, was sought in marriage by the son of a heathen prince who was originally named Holofernes, but afterward, when a christian, was called Ætherius. Her father was forced to yield to the demand; but Ursula made it a condition that her suitor should become a Christian, and that she should be allowed a space of three years, during which she proposed, in company with her maidens, to each of whom should be assigned a thousand companions, and a three-oared galley to convey them, to make a voyage of pious pilgrimage. The conditions were accepted; the maidens, to the number of 11,000, were collected from all parts of the world; and at length the expedition set sail from the British coast. Arriving at the mouth of the Rhine, they sailed up the river to Cologne, and thence upward to Basel, where, leaving their galleys, they proceeded by land to visit the tombs of the apostles at Rome. This pilgrimage accomplished, they descended the river to Cologne, which, however, had meanwhile fallen into the hands of an army of Hunnish invaders, under the headship of a chief, who, although not named, is plainly the Attila of history. Landing at Cologne in ignorant security, the pious virgins fell into the hands of these barbarous heathens, by whom they were all put to the sword with the exception of Ursula, who, for her beauty's sake, was reserved as a prize for the chief. She, too, however, as well as another maiden who had at first concealed herself in terror, demanded to join her companions in martyrdom; and thus the full number of 11,000 victims was made up. Heaven, however, interposed. A host of angel warriors smote the cruel Huns; Cologne was again set free; and in gratitude to their martyred intercessors, the citizens erected a church on the site still occupied by the church now known under the name of St. Ursula. Such is the legend as told by Sigebert, although it has undergone some modifications in later hands. The improbabilities and anachronisms of this legend were early observed; and it became the subject of an animated controversy soon after the reformation. On the one hand, the centuriators of Magdeburg exposed its weak points with unsparing severity; on the other, a Jesuit father, Crombach, devoted an entire folio volume to the vindication of the substantial truthfulness of the narrative. Many suggestions have been offered as explanations of its most startling improbability—viz., the alleged number of the martyred victims, 11,000. One of these is, that this belief arose from the name of a virgin who was really the companion of Ursula's martyrdom—*Undecimilla*. The record of the martyrdom in the calendar thus being "Ursula et *Undecimilla VV.*, "Ursula and Undecimilla Virgins," was easily mistaken for "Ursula et *Undecim millia VV.*," "Ursula and *eleven thousand virgins.*"

Secular inquirers into the origin of the Ursula legend deny that it has the slightest foundation in any historical facts. They find the first traces of the reverencing of these

virgins in martyrologies and missals of the latter half of the 9th c., in which mention is made either of a very small number of virgins whose names are given, or a larger indefinite number without names. In one metrical martyrology of this period, by Wandalbert, a monk of Prüm, they are already spoken of as thousands; and after the end of the 9th c. the number of 11,000 is found in the calendars. The name of Ursula, however, does not occur till after the 10th c.; and it was not till the 12th c. that the reverence for Ursula became predominant over that of the associate virgins. With the 12th c. begins the discovery of the sacred bones. The *ager Ursulinus* was revealed by a vision in 1106; and at first, single skeletons were raised with the greatest solemnity; but beginning with 1155, the digging up of the field was carried on systematically for nine years, in the course of which thousands of skeletons were found, male as well as female, besides coffins, stone tablets with inscriptions, and the like. What the several relics were was revealed to a nun named Elizabeth, then living in the diocese of Trier, to whom the holy martyrs appeared in visions. In this way were identified a pope of the name of Cyriacus, an archbishop, several cardinals, bishops, and priests, and also Ætherius, Ursula's bridegroom, along with whose title the cross, a crown, and other royal insignia were represented. It was also explained how all these men came to be in the company of the pious virgins. Even the children's bones found among the others were accounted for by revelations made forty years later to an abbot at Arnsberg, which confirmed and supplemented those of Elizabeth. The numerous human remains found in the Ursulan field at the north side of the city have been accounted for by antiquaries, by making it out to have been the burying-ground of the ancient Roman *Colonia Agrippina*. The origin of the legend is accounted for by Schade in his work *Die Saga von der Heiligen Ursula* (Han. 1854), on the theory that it is a Christianized relic of old German paganism, in which Ursula has taken the place of the ancient goddess worshiped by the Scandinavians as Freyja (q.v.), and still remembered by the German people under the names of Berchta (q.v.), Hulda (q,v.), etc., and in Sweden by the very title of "Old Urschel."

But without pursuing further this curious inquiry, it will be enough to say, as concerns the Roman Catholic view of the matter, that while the most learned of the Catholic hagiographers, putting aside the idea of a directly and intentionally invented narrative, have traced the origin of the legend to a real historical massacre of a very large number of Christian maidens, which took place during the invasion of Attila, and soon after the celebrated battle of Chalons in 451, all the modern writers of that church are agreed in regarding the details of the narrative, the number, the pilgrimage to Rome, the interposition of the heavenly host, etc., as legendary embellishments of the mediæval chroniclers.—See, for the full exposition and vindication of the history, Crombach, *Ursula Vindicata* (fol. Coloniæ, 1647); and for a more critical exposition of the historical foundations on which it rests, Binterim's *Calendarium Eccles. Germ. Colon.* (1824); *Zeitschrift für Phil. u. Kathol. Theologie* (1850); Kellerhoven, *La Légende de Sainte-Ursula* (1862).

URSULINES, a religious order of females in the Roman Catholic church, taking their name from the saint and martyr who forms the subject of the above article. They take their origin from Angela Merici, a saint of the modern church, b. according to the more received account, at Desenzano, in the latter part of the 15th century. She formed at Brescia an association of young females who bound themselves by a vow to labor for the tending of the sick, the instruction of children, the relief of poverty, and other such works of charity. After a time, a rule, in twenty-five chapters, was projected by Angela, and finally approved by the bishop of Brescia, cardinal Francis Cornaro. Angela was herself chosen as the first superior, in the year 1537, the community even at that time numbering as many as 76 sisters. During the lifetime of Angela, and for more than twenty years after her death, which occurred in 1540, the congregation was confined to the diocese of Brescia; but in the year 1565, a house was opened at Cremona; and with the approval of popes Gregory XIII. and Clement VIII., it was spread over many dioceses of Italy. It was warmly encouraged by St. Charles Borromeo, and at his death there were no fewer than 28 convents of the order in his diocese, comprising above 600 nuns. Soon afterward, it was established in France, where one of its most distinguished members was the celebrated sister, Madeleine de St. Beuve. It was in France that the sisters, although from the beginning they had been engaged in teaching, first formally added to their religious vows that fourth vow to devote themselves to the instruction of female children, which has since formed the great characteristic of the order. They were introduced into Savoy by St. Francis de Sales in 1635; and in 1639, a convent was opened in Quebec, in Canada. About the same time, they were introduced into Germany—at Vienna in 1660, and at Freiburg, Kitzingen, and Prague soon afterward—where they have continued to teach with great success; and their convents in various parts of Germany, but especially in Austria, at present number 36. The Ursuline sisters have several educational establishments in Ireland, in England, and in the United States, and may fairly claim the merit of having been mainly instrumental in maintaining among Catholics the education of female youth of the higher order through the 17th and 18th centuries. They have found many competitors among the younger sisterhoods of modern times.—See *Journal des Illustres Religieuses de l'Ordre des de Ste. Ursule*, 4 vols. 4to (1690); *Chroniques de l'Ordre des Ursulines*, 2 vols. (Paris, 1676).

URTICA'CEÆ, or URTI'CEÆ, a natural order of exogenous plants, consisting of trees, shrubs, and herbs, natives of almost all parts of the world. According to many botanists, the order includes about 600 known species; while others, restricting it by separating from it several distinct orders, reduce it to about half that number, of which the common nettle may be regarded as the type. The leaves of all are alternate, furnished with stipules, and generally very rough, sometimes with stinging hairs. The inflorescence is various; the perianth usually divided, but sometimes a mere scale; the stamens inserted into the perianth, equal in number to its segments, when it is divided, and inserted at their base; the ovary free, one-celled, containing a single ovule. The fruit is a kind of nut, surrounded by the persistent and sometimes fleshy perianth, sometimes winged; and sometimes the fruits are variously aggregated. Under this description are comprehended *cannabinaceæ* (q.v.), *ulmaceæ* (q.v.), *moraceæ* (q.v.), and *artocarpaceæ* (q.v.), as well as the restricted urticaceæ, which have filaments curved in bud, and turning backward elastically when the anthers are bursting, the fruit an unopening nut. The juice of the restricted urticaceæ is watery, not milky; the wood in the arboreous or shrubby species, which are all tropical, is remarkably soft and light. The fiber of the bark of some is valuable. It is among the restricted urticaceæ that species covered with stinging hairs are found. See BŒHMERIA, NETTLE, NEILGHERRY NETTLE, and PELLITORY.

URTICA'RIA. See NETTLE-RASH.

URUGUAY', otherwise BANDA ORIENTAL DEL URUGUAY—i. e., "the eastern bank of the Uruguay," is a small South American state, bounded on the n. and n.e. by Brazil, on the e. and s.e. by the Atlantic, on the s. by the Rio de la Plata, and on the w. by the Uruguay. It is nearly square in shape, and its greatest length and its greatest breadth are over 300 miles. Area, 72,110 sq. m.; pop. '95, (est.) 792,800. Uruguay is divided into nineteen provinces. In the south, all along the Rio de la Plata, and as far north as the Rio Negro, the country is a sort of terraced upland, with a bold, broken treeless coast-line, possessing some excellent harborage; while the shores facing the Atlantic are low and sandy. Further east, rises a woody plateau; but high, bare, grassy plains, traversed by ranges of low hills, seem to be the predominant feature. The climate is mild; rain falls pretty copiously in winter, but is rare in summer. The most important rivers are the Rio Negro, the Daiman, the Arapey, the Yaguaron, and the Sebollati. The wild animals embrace the tapir, deer, ounce, monkey, paca, rabbit, and fox; and large packs of wild dogs infest the plains. Although the soil is naturally fertile, agriculture is in a backward condition, and the chief industry of the country is the raising of cattle and sheep. The lands are, for the most part, held in large estates, and the owners are content with the revenues derived from the large flocks and herds. Where wheat is grown the crops are excellent, but not much attention is devoted to raising it. Alfalfa is among the leading feed crops and grows abundantly. Manufactures are not important, nor is the foreign trade of Uruguay considerable. Of late years much attention has been given to grape growing, and the annual yield is on the increase. The imports consist largely of manufactures and food products, and the exports of animals and animal products. With the United States the export trade in 1896 amounted to about $742,000, and the import trade to about $857,000. The constitution of Uruguay was formed in 1830. The form of government is republican, the executive being vested in a president, chosen for four years, and the legislative in a parliament of two houses.

Uruguay was originally colonized by Spanish settlers from Buenos Ayres, on the other side of the La Plata; but the territory which forms the natural limit of Brazil on the south was claimed by Portugal, and a war ensued between the two nations for its possession which terminated in favor of Spain. Uruguay was now attached to the viceroyalty of Buenos Ayres, and received the name of *Banda Oriental*—i.e., as has been explained above, the country on the eastern bank of the Uruguay. Its independence was secured by treaty in 1828, when it took the title of *Republica del Uruguay Oriental;* but, like most of the South American republics, it has suffered frequently from internal discords.

URUGUAY RIVER, in South America, rises in the province of Santa Catharina, Brazil; after a course of about 70 m. n., increased by the Pelotas, the Pepiri-Guaçu, and other streams, turns s.; flows between the Argentine provinces of Entre-Rios and Corrientes, and the Brazilian province of São Pedro; is joined by the Ibicui, by the Quaraim, which is 160 m. long, and separates Uruguay and Brazil. At this point the Uruguay is 1500 yards wide; and from here to its mouth is the boundary line between Uruguay and the Argentine republic. It is joined by numerous tributaries, of which the Rio Negro is the largest, and in lat. 34° unites with the Parana to form the Plata. It is navigable for flat-bottomed steamers for about 500 m., and has a total course of about 1000 miles.

URUMEYAH, a t. of Persia, province of Azerbaijan, 70 m. w.s.w. of Tabriz, in a wide and fertile plain. Extensive fruit and vegetable gardens are situated both within and without the walls. The houses of the better classes are lofty, spacious, and sumptuously furnished; and many of those of the poorer classes are tastefully adorned with flowers and vines. Urumeyah has a flourishing Protestant mission; it has a pop. of about 25,000, a large number of whom are Nestorian Christians and Jews. Urumeyah was anciently known as *Thabarma*, or *Thebarmæ*, and was held in great veneration by the

Persians, by reason of the legend which fixed it as the birth-place of Zoroaster (q. v.). In 624 A.D. the town, including a magnificent fire-temple, was destroyed by the emperor Heraclius.

URUME'YAH, URUMIJAH, URMEA, LAKE, called also the *lake of Maragha* (q.v.), *lake of Tabriz*, and by the neighboring peoples *Kapauta* (Armen. *kapoit*, blue), the principal lake of Persia, is situated in the west of Azerbijan, about 64 m. s.w. from Tabriz. The lake, which is 4320 ft. above sea-level, is about 80 m. in length from north to south, has an average width of 25 m., and contains about 1420 English sq. miles. It is one of that class of lakes which receive but do not emit streams; and despite the fact that its feeders include such rivers as the Aji-su, 180 m. long; the Jage-tu, 140 m. long; and the Ta-tu, 90 m. long, it has only an average depth of 12 feet. The water is largely impregnated with saline substances (according to one authority, the salts constitute 25 per cent of the whole weight), and is so heavy as to be little ruffled by the strongest wind. No fish or mollusca are found in it. Six large isles, and a multitude of islets and rocks, show themselves just above its surface, being mostly grouped together near its center. The lake is fast drying up, leaving a gradually widening beach of thick saline incrustation, which supplies with salt the whole of Kurdistan. The lake was known in ancient times as *Matiana*, or *Mantiana*.

URUMTSI, a city at the base of the Thian-Shan mountains, in the Chinese province of Urumtsi in central Asia; pop. about 140,000. It was formerly the center of a great trade with the surrounding country, with Russia, Persia, etc. Its commercial importance was ruined by the Dungans, a Mussulman nation in n. China, who revolted in 1862, on account of excessive taxation, and entered s. Mongolia, taking possession of Urumtsi.

U'RUS, a great animal of the ox kind, which anciently inhabited the forests of central Europe, and is described by Cæsar (*Bell. Gall.* vi. 28) as common in the great Hercynian forest; as scarcely less than an elephant in size—an evident exaggeration—but otherwise resembling an ox, of great strength, of great swiftness, and of great fierceness. He mentions that the horns were very different from those of the oxen of Italy—large, spreading, and sharp. This character is found in the wild cattle of Chillingham and other parks in Britain, and in some of the Highland breeds of oxen; and the probability seems to be that the urus was the wild original of the domestic ox, and not a bison, nor any now extinct species, although some authors maintain a contrary opinion. See a monograph by Storer on the *Wild Cattle of Great Britain* (1879).

URVAS'Î. See PURÛRAVAS.

USAGE, in law, is generally employed to denote that long and uniform practice in mercantile transactions or trade, which will be regarded by courts in construing the meaning of contracts. To have such weight the usage must be uniform, certain, reasonable, and not contrary to law; but need not be "immemorial." By the aid of the principles of usage, words and expressions of doubtful meaning may often be explained, but courts are very cautious in accepting the existence of an alleged usage.

USBEGS, or USBEKS, a people of Turkish race, who, at the close of the 15th c. of the Christian era, invaded and conquered the numerous principalities into which Turkistan was at that time divided, and have ever since maintained dominion over the country. At the present day they are for the most part a settled people, occupying themselves in the cultivation of the soil and in trading, and are scattered over Russian, Independent and Chinese Turkistan. The most probable supposition regarding their origin is that they immigrated from Kiptchak (q.v.), and assumed the name of Usbegs, from Usbeg, one of their chiefs. The Usbegs of Khiva, Bokhara, Khokan, and of Chinese Turkistan differ from each other in language, manners, and customs. Those of Khiva speak a dialect of the Turkish, are honest and generous, and destitute of the treachery and duplicity which are so characteristic of oriental civilization, are passionately fond of music and poetry, and though zealous Mohammedans, still retain many of their ancient heathen usages. They pride themselves much on the purity of their Usbeg descent, but most of them show evident traces of an admixture of Iranian blood. The Usbegs of Bokhara have become largely mingled with the Tajiks, and have consequently lost many of their national characteristics. Those of Khokan are very different from the two previous, and are as much Kirghis, Kiptchaks, and Kalmucks as they are Usbegs; the fact that the Usbegs have been the dominant race in Turkistan for three centuries and a half, having given the name such a prestige of nobility and good breeding, that it is generally assumed by such members of other races as settle in cities.

USE AND OCCUPATION is the technical name given in the law of England to the beneficial enjoyment of premises by a tenant, who occupies the real property of another, such as houses and farms. In all cases where a person has had use and occupation of another's premises, with the assent of the owner, an action lies for the value thereof, which value corresponds to rent under an ordinary lease. Hence, where it is doubtful whether there has been a valid lease executed between the parties, the landlord can nevertheless recover rent under the head of use and occupation.

USEDOM, an island belonging to Prussia, lies at the mouth of the Oder, and together with the island of Wollin, shuts off the Stettiner Haff from the Baltic. It is of very

irregular shape, being much indented by branches of the Haff, is 34 m. in extreme length, and 15 m. broad. Area about 148 sq. miles. On its n.e. side is the port of Swinemünde (q. v.); on the s. side is the small town of Usedom.

USES, in the law of England, is the old name for trusts, which has superseded the other in most respects. Uses and trusts correspond to the *fidei commissum* of the Roman law. A use was a confidence reposed in another who was tenant of the land, or *terre-tenant*, that he should dispose of the land according to the intention of the *cestui que use*, or him to whose use it was granted, and suffer him to take the profits. See TRUST.

USH'ANT (Fr. *Ouessant*), an island in the Atlantic ocean, belongs to France, and is included in the dep. of Finisterre, from the w. coast of which it is distant about 20 miles. It is the largest of a small group of islets called the *Iles d'Ouessant*, has an area of 7 sq. m., and contained, '91, 2490 souls. The coasts are escarped and difficult of access; the soil is fertile. The inhabitants are employed in fishing, and in rearing cattle and horses.

USHAS (from the Sanskrit *ush*, "to shine, to burn," and kindred with the Greek *ēōs* or *heōs*, and the Latin *aurora*), "the dawn," is one of the female deities of the Vedic religion of India (see INDIA, sec. *Religion*), and among these is invoked with special predilection by the poets of the R'igveda hymns. The invigorating influence which the dawn exercises on body and mind, and the luminous and other phenomena connected with the beginning of the day, form the subject of some of the best portions of Vedic poetry; and out of them Ushas arises as one of the most pleasing goddesses of the ancient Hindu pantheon. She is invoked as "the affluent," as "the giver of food," and "the bringer of opulence;" she is asked to bestow on the pious "riches with horses and cattle," "posterity and troops of slaves;" and she is praised for the many boons she has showered on the worshipers who were liberal to her. She is the goddess "endowed with an excellent intellect," and the "truthful," or fulfiller of her promises. "She animates the diligent;" when she appears, "bipeds and quadrupeds (are in motion)," "the winged birds flock around from the boundaries of the sky," and "men who have to earn their bread quit their homes." She rides in a "golden chariot," which is "ample and beautiful;" and the Sanskrit word *go* meaning a cow (or, as a masculine, an ox), and also a ray of light, she is not only "the mother of the rays of light," or attended by them, and rays of light are her banner, but her chariot is drawn by "ruddy *kine*," or, as they are sometimes called, "ruddy oxen." Less frequently she is spoken of as traveling with horses; for the horse, as a symbol of light, is more especially appropriated to the god of the sun. The relation of Ushas to other Vedic deities is of a twofold, a physical and a ritual, character, inasmuch as the phenomena of dawn are connected with other phenomena of nature, and as certain religious ceremonies are performed at daybreak. On these grounds, she is frequently addressed as "the daughter of heaven;" and when her "parents" are spoken of, the commentator explains this word as implying "heaven and earth." She is further called the daughter of night (night being the precursor of the dawn); but, on other occasions, she is also spoken of as having night for her sister. She is, besides, the sister of the two luminous deities *Bhaga* and *Varun'a*, and the faithful wife of *Sûrya*, the sun. According to an old commentator (*Yâska*), she would in one passage of the R'igveda also be the deity "who has the sun for her child," "either because the sun is her companion, or because he absorbs the moisture (i.e., the frost);" but as *rus'advatsâ*, the word, so interpreted, admits also of another rendering, it is doubtful whether she bears this epithet, the more so as in another passage the sun is said to follow Ushas as a man follows a woman. The As'wins being the luminous twin-gods, who probably represent the transition from darkness to light, and therefore that intermingling of both which becomes inseparable (see John Muir's "Contribution to a Knowledge of the Vedic Theogony and Mythology," in the *Journal of the Royal Asiatic Society*, new series, vol. ii., 1866), Ushas is called their "friend"—according to Sâyan'a, also their sister; she "follows their luster," and "awakes" them to partake of the soma prepared for them; and in their turn they are asked "to unite with the dawn." Another god, who originally on physical grounds is associated with Ushas, is *Indra* (q.v.), the ruler of the bright firmament. He "generates (i.e., causes to appear) sun and dawn," and "appoints them to their office," which is that of dispelling darkness; but though, "when (in the morning), desiring (the soma), he honors the dawn," his ascendency during the day becomes fatal to her; for then "he slays her," "breaks her chariot;" and "her shattered chariot reposing on (the banks of) the river Vipás', she departs from afar." Most of these deities become, in consequence, associated with Ushas also as sharers in certain sacrifices which are offered to her; and besides these, Agni, the god of fire, who carries the offerings to the gods, and Soma (q.v.). Like many of the most poetical deities of the Vedic creed, also Ushas is excluded from the Hindu pantheon of the classical period. Her place is there taken by *Arun'a* (the ruddy), whom the epic poems and the Purân'as make the son of the patriarch Kas'yapa and his wife Vinatâ, and the younger brother of Garud'a, the bird-vehicle of Vishn'u. According to the *Mahâbhârata*, he was appointed by the gods to the office of charioteer of the sun, in order to intercept his fiery heat, when the sun, angry with the gods for being exposed to the enmity of Râhu (q.v.), it was feared, would consume the world. Where repre-

sented, *Arun'a* is therefore seated before the sun on his chariot, driving his horses; but as the legends deprive him of his legs, his body is seen perfect to his knees only.

USHER, James, Archbishop of Armagh, and by common consent the most learned prelate that ever adorned the Irish Protestant church, belonged to one of the oldest Anglo-Irish families, and was born in Dublin, Jan. 4, 1580. His father, Arnold Usher, one of the clerks in chancery, was a gentleman of good estate, and his uncle, Henry Usher, preceded him in the archbishopric of Armagh. At the age of 13 he entered Dublin college, where his predilection for history soon revealed itself. Having resolved to devote himself to the service of the church, he proceeded, after the solid fashion of the times, to read up the entire literature of ecclesiastical antiquity—a task which occupied him from his 20th to his 38th year! In 1601, he was ordained deacon and priest, and was shortly after appointed preacher of Christ church, Dublin. In 1607, he was chosen to the chair of divinity, a post which he held for 13 years. In 1609, he made one of his numerous visits to England, in the course of which he made the acquaintance of the most distinguished scholars of the age. In 1613, his first publication appeared, entitled *De Ecclesiarum Christianarum Successione et Statu*, which was designed as a continuation of Bishop Jewell's *Apology*. The work was divided into three parts, of which only the first, reaching to the period of Hildebrand, and part of the second, were finished. In 1615, he was appointed, by a convocation of the clergy held at Dublin, to draw up a series of articles (the number amounted to 104) relating to the doctrine and discipline of the Irish Protestant church, in which the doctrines of predestination and reprobation (of which Usher was an unflinching apologist) found prominence. These and other views, such as, that bishops were not a different *order* from presbyters, that the Sabbath should be strictly enforced, that no toleration should be granted to Catholics, laid him open to the charge of Puritanism; but as his loyalty to the principle of monarchy was undoubted, he suffered no diminution of the royal favor; on the contrary, king James promoted him to the bishopric of Meath in 1620; and in 1623, constituted him a privy-councilor of Ireland. Two years later, he was raised to the highest ecclesiastical dignity in the kingdom, the archbishopric of Armagh, and in his official capacity "vigorously" opposed the toleration of popery and the spread of Arminianism. In 1632, Usher published *Veterum Epistolarum Hibernicarum Sylloge*, a collection of letters out of several ancient MSS., concerning the state of the Irish church from 592 to 1180; in 1638, *Emmanuel, or a Treatise on the Incarnation of the Son of God;* in 1639, *Britannicarum Ecclesiarum Antiquitates*, which is said to contain "a most exact account of the British church; from the first planting of Christianity, twenty years after our Saviour's crucifixion, down, both in Britain and Ireland, to the end of the 7th c.;" in 1641, *The Judgment of Dr. Reynolds concerning the Original of Episcopacy defended; The Original of Bishops; The Power of the Prince and the Obedience of the Subject*, etc. When the civil war broke out, Usher, who was in England at the time, espoused the side of the king, refused to sit, when nominated, among the assembly of divines at Westminster, and made himself very obnoxious to the parliament by the sermons which he preached at Oxford. When the fortunes of the king began to decline, Usher left Oxford; his property and revenues in Ireland were seized, and after a residence in Wales and elsewhere, he came to London in 1647, where, in spite of his royalist sympathies, he was chosen by the benchers preacher of Lincoln's Inn, a post which he retained till his death, March 21, 1656. Cromwell, who had a great respect for his learning, ordered his remains to be interred with great magnificence in Erasmus's chapel in Westminster abbey. Usher was a man of undoubted ability and of enormous erudition, pious and free from worldly ambition; but he lacked force of character, real insight and intellectual power, hence, though pronounced by Dr. Johnson "the greatest luminary of the Irish church," he exercised less influence over the course of contemporary events than the humblest of Cromwell's Ironsides. Nor can it be shown that posterity is very deeply indebted to him for more than the example of a virtuous and studious life. Usher's chief works, besides those already mentioned, are his edition (1644) of the *Epistolæ* of Polycarp and Ignatius; his treatise *De Romanæ Ecclesiæ Symbolo* (1647); *Dissertatio de Macedonum et Asianorum Anno Solari* (1648); and *Annals of the Old Testament* (1650–54), a chronological work. After his death, there were published (from his numerous MSS.), *Chronologia Sacra*, etc. (Oxford, 1660), by which and his *Annals* he is most widely known; a volume of *Sermons; Historia Dogmatica Controversiæ inter Orthodoxos et Pontificios de Scripturis et Sacris Vernaculis* (Lond. 1690); *A Collection of three hundred Letters written to James Usher, Lord Archbishop of Armagh*, to which is prefixed a life of the archbishop by his chaplain, Richard Parr, D.D, (Lond. 1686). A collected edition of Usher's works, in 16 vols., with a new biography, was published at Dublin in 1841, by Dr. Elrington.

USHER of the **BLACK ROD**, one of the officers of the Order of the Garter (q.v.), coeval with the institution of the order, and originally called "Hostiarius capellæ regis infra castrum de Windsor." The rod from which his title is derived is of ebony, mounted with gold 3½ ft. in length, having at the top a lion sejant, holding before him in his forepaws a gold shield charged with the royal cipher in gold surrounded with the garter. He has a mantle like that of Garter King of Arms, and his badge is a gold knot surrounded with the garter, and ensigned with the royal crown. It is the practice to unite this office with that of the king's first gentleman usher daily waiter at court, who is one of the

chief officers of the house of lords. In this capacity it is one of the functions of the Gentleman Usher of the Black Rod, or of his deputy, who is known as the Yeoman Usher of the Black Rod, to desire the attendance of the commons in the house of lords when the royal assent is to be given to bills by the sovereign or lords commissioners; also to execute orders of commitment for breach of privilege and contempt, and to assist at the introduction of peers, and other ceremonies of the upper house.

USHER OF THE **GREEN ROD**, one of the officers of the Order of the Thistle (q.v.), whose duties consist in attendance on the sovereign and knights when assembled in chapter, and at other solemnities of the order. The rod from which the title is taken is of green enamel, three feet in length, ornamented with gold, having on the top a unicorn of silver, holding before him an escutcheon charged with the cross of St. Andrew.

USKUP, or SCO'PIA, a t. of European Turkey, capital of the vilayet of Kasavo, on the Vardar, 120 m. n.w. of Salonica. The town, which is built on hilly ground, contains a number of mosques, with black domes and minarets, interspersed among fruit trees. Here are the ruins of an ancient Roman aqueduct, consisting of 55 arches. Leather is manufactured. Pop. estimated at 28,000.

USNEA, a genus of lichens, having a much-branched thallus, with an elastic thread in the center. Some of the species are natives of America. They grow on trees, and are generally pendulous. They contain the vegetable principle called *usnine*, which, however, is also found in many other lichens. They are sometimes used in dyeing, like archil and cudbear. From their appearance, many of the species of usnea receive the popular name of BEARD-MOSS. See illus., MOSSES, ETC., vol. X.

USTILA'GO. See SMUT.

U'SUFRUCT, in Scotch law, is adopted from the Roman law, to denominate one of the three personal servitudes, which were use, usufruct, and habitation. Usufruct is better known under the name of life-rent (q.v.), or estate (q.v.) for life.

USURY. See INTEREST.

UTAH, a western state of the U S., between lat. 37° and 42° 10′ n. ; long. 109° and 114° w. ; bounded on the n. by Idaho and Wyoming; on the e. by Wyoming and Colorado ; on the s. by Arizona, and on the w. by Nevada ; average length from n. to s., 350 m. ; average breadth, 260 m. ; land area, 82,190 sq.m. ; gross area, 84,970 sq.m., or 54,380,800 acres.

HISTORY.—The state, which derives its name from the Utah or Ute Indian tribe, was originally a part of Upper California; was acquired by the U. S. from Mexico by treaty in 1848; and was first explored by the Spaniards about 1540. The Mormons, driven from Illinois and Missouri, emigrated hither in 1847–48, and established themselves in what was then almost an unknown region, which they named Deseret. Under the superintendence of their high-priest, Brigham Young, Salt Lake City was soon founded; in March, 1849, a convention was held and the state of "Deseret" organized. Admission was refused by congress, and in 1850, Sept. 9, a territorial government was formed, over which Young was appointed governor. The territory at that period included parts of Colorado, Nevada, and Wyoming, and had an area of more than 220,000 sq. m. In 1857, however, Young set at defiance the federal authority, and it became necessary for the U. S. government to send an armed force into the territory to compel obedience. In 1862 the Mormons formed a state constitution, and demanded admission to the union as the "state of Deseret." The refusal caused further unpleasant relations. The opening of mines in the territory brought about the emigration of many "Gentiles" to Salt Lake City and the surrounding region, which to some extent worked a change in Mormon authority. The enforcement of the "Edmunds bill" (see MORMONS), which was passed by congress in 1882, providing for the suppression of polygamy, and disfranchising polygamous Mormons, met with stubborn resistance, and was followed by a bill in 1887 restricting the suffrage and escheating a vast amount of Mormon property, real and personal. This led the Mormons in 1890 to pledge themselves to discontinue the practice of polygamy. In 1886 the Mormons made another futile attempt to secure statehood; but it was not till after their full agreement to obey the laws of congress that that body sanctioned admission as a state, which was accomplished Jan. 4, 1896.

TOPOGRAPHY.—Utah is an immense basin 4000–5000 ft. above the level of the sea, surrounded by mountains, which at some points reach the altitude of 8000–13,000 ft. The Wasatch range, about 12,000 ft. in altitude, crossing from n.e. to s.w., divides it into two portions. Another important range, the Uintah Mts., lies near the Wyoming border, and to the w. of the Wasatch chain are numerous peaks, ridges, and isolated hills. In the s.e. lofty plateaus of great extent are found. Excepting the Green and Grand rivers in the e. and s.e., which unite to form the Colorado, and their tributaries, the streams as a rule flow into the Great Salt lake in the n.w. part of the state, or similar inland bodies of salt water. Great Salt lake (q. v.) is about 80 m. long and from 30 to 50 broad. Its area is 3000 sq. m. and its waters are 22 per cent. salt. Utah lake (q. v.) has an area of 130 sq. m., and is connected by the Jordan river with Great Salt lake. Sevier lake, another large sheet of water, has no outlet, but receives from the N. Sevier river, 150 m. in length. A portion of the great cañon of the Colorado is in Utah. Salt and thermal springs are numerous.

GEOLOGY AND MINERALOGY.—The rocks are mostly primitive, and rich in granite, jasper, syenite, porphyry, and quartzes, showing everywhere evidences of volcanic action.

AREA AND POPULATION OF UTAH AND COLORADO BY COUNTIES.

LIBRARY
UNIVERSITY OF ILLINOIS

There are also ridges of carboniferous limestone containing calcareous spar; and near Salt Lake City occur boulders of serpentine, fine gray granite, sandstones, conglomerates, talcose and striated slates, gypsum, limestone, and marble of every hue in large masses. Gold, silver, and lead ores exist in large quantities, and iron ores of all rich qualities are very abundant. In Iron co. there are rich deposits of hematite and magnetite. Other deposits of large extent have also been found in the Castle valley region and in the n. part of the state. There are great quantities of bituminous coal, also copper, zinc, sulphur, alums, rock salt, asphaltum, borax, and petroleum.

Zoölogy and Botany.—The antelope, black-tailed deer, Rocky Mountain sheep, wolf, panther, grizzly bear, beaver, fox, and porcupine are found, over 170 species of birds, and the swan, pelican, goose, quail, grouse, etc. Perch, bass, pike, and large salmon trout are taken in the rivers or lakes. Generally, vegetation is not luxuriant, and timber, except pines and firs in the mountains, scarce. The country has good grass for grazing, and some wild fruits.

Soil, Climate, and Agriculture.—The soil of the lowlands is somewhat alkaline, extremely sandy in portions, and very dry. Much of it, however, has been reclaimed by irrigation and rendered profitably productive. The precipitation of rain on the highlands is sufficient for vegetation. The mean annual temperature in spring is 46.20°; in summer, 73.57°; in winter, 30.38°; the average annual rainfall is 15.10 inches. Agriculture and mining are the principal industries, the chief localities of the former being the valleys of Sanpete, Weber, Salt Lake, Jordan, Tooele, Malade, Rush, Sevier, and Rio Virgin. The mountains and high valleys produce an abundance of nutritious grasses, in consequence of which a large live-stock industry has been developed. In 1890 the farm acreage was 1,323,705, and the value of farms, with buildings and fences, was reported at $28,402,780, or more than double that of 1880, an improvement attributable in large measure to extensive irrigation. The principal cereal productions are wheat (nearly 3,000,000 bushels), oats (nearly 1,000,000 bushels), corn, barley, and rye. The potato crop exceeds 800,000 bushels, and the hay crop is about 500,000 tons. The total value of the crops enumerated is over $5,000,000. The farm and ranch animals exceed $10,500,000 in value, and the most numerous are sheep (about 2,000,000), cattle (over 400,000), and horses.

Manufactures and Mining.—In 1890 there were 531 manufacturing establishments, with an aggregate capital of $6,583,022, and employing 4980 hands. The wages paid amounted to $2,715,805, and the value of products was $8,911,047. The chief manufactures are flour and grist mill products, planing mill products, packed meat, brick and tile, woolen goods, foundry and machine shop products, lumber mill products, salt, malt liquors, and cigars. Mining in Utah has become exceedingly profitable. Rich carbonate strikes have been made at Eureka, 90 miles south of Salt Lake City, and the onyx vein on the west shore of Utah lake is said to be one of the most valuable in the world. The mines of Utah, however, are not always worked to the greatest advantage. Between 1871 and 1891 the total product was valued at $150,000,000, two-thirds of which was in silver, a little less than one-third in lead, and the balance in gold, copper, mixed antimony, cinnabar, and sulphur. The total value of the mineral productions in 1896 was estimated at $15,897,266, of which silver, gold, unrefined lead, and copper were the most important. This was a slight increase over the total of the previous year, when the silver output had a coining value of over $9,500,000, and the gold over $1,350,000. The production of silver in 1897 was estimated at 8,100,000 fine ounces, an increase of over 600,000 ounces in a year, and of gold, 97,906 fine ounces, an increase of about 31,500 ounces. There are a number of natural gas and oil wells near Salt Lake City.

Transportation.—The state is crossed by branches of the Union and Southern Pacific railroads, and has over 1400 miles of through and local roads. The latter have a capital of about $20,000,000; funded debt, nearly as large; total investment $40,000,000; and net earnings, over $750,000. The cost of local roads and equipments exceeds $35,500,000.

Banks.—On Oct. 31, 1896, there were 11 national banks in operation, with capital $1,900,000, deposits $2,624,924, and reserve $1,013,096; 9 state banks, with capital $1,165,000, deposits $924,710, and resources $2,456,627; and 8 stock savings banks, with capital $800,000, deposits $2,655,356, and resources $3,874,155.

Religious Denominations, Education, etc.—In 1890 there were reported 427 church organizations; 280 church edifices; 157 halls used for religious purposes; 128,115 communicants; and church property valued at $1,493,791. The church of Jesus Christ of Latter-day Saints (Mormon) had 192 church buildings, 118,201 members, and property valued at $736,916. The completion of the great temple at Salt Lake City (q.v.) in 1893 increased the value of Mormon church property by several millions. Other denominations, in their order, are the Roman Catholic, Methodist Episcopal, Protestant Episcopal, Presbyterian, and Congregational. The state constitution provides that the public school system shall include kindergarten schools, common schools of primary and grammar grades, high schools, a state university, a state agricultural college, and such other schools as the legislature may establish. The state institutions include a university at Salt Lake City, agricultural college at Logan, state school for the deaf and dumb

and blind at Ogden, and state industrial school at Ogden. The public school population exceeds 86,000; enrollment, 62,000; average daily attendance, 40,000; school houses, 900; value of school property, $2,350,000; annual expenditure, $900,000.

GOVERNMENT. — The state constitution decrees the complete separation of church and state; guarantees perfect toleration in matters of religion; gives to women the rights to vote and hold office; condemns polygamy; and provides that eight jurors may sit in judgment, and six may find a verdict. The legislature meets in biennial sessions, limited to 60 days; members receive not more than $4 per day and mileage limited to ten cents a mile. The executive department consists of a governor, secretary of state, auditor, treasurer, attorney-general, and superintendent of public instruction, each to hold office for four years. The supreme court consists of 3 judges till 1905, when the number may be increased to 5; terms, after the first, 6 years each. The governor, justices of the supreme court, and attorney-general constitute a board of pardons; the governor, secretary of state, and attorney-general, a board of state prison commissioners; the governor, treasurer, and auditor, a board of insane asylum commissioners; and the governor, attorney-general, and superintendent of public instruction, a board of reform school commissioners. For immediate needs the state was divided into 7 judicial, 27 representative, and 12 senatorial districts.

POPULATION. — In 1850, 11,380; 1860, 40,273; 1870, 86,786 (excluding Indians); 1880, 143,963 — 501 Chinese, 807 civilized Indians; foreign born, 43,994; male, 74,509; female, 69,454; dwellings, 26,710; families, 28,373; persons to sq. m., 1.7; territorial population, 1890, 207,905. There are 27 cos.; for pop. 1890, see Census Tables, XV. In 1890 the principal cities and towns, with their population, were, Salt Lake City, 44,843; Ogden, 14,889; Provo City, 5159; Logan, 4565; Park City, 2850; Springville, 2849; Mount Pleasant, 2254; Spanish Fork, 2214; Brigham City, 2139; Payson, 2135; and Nephi, 2034. The civilized Indians in the state number about 600.

UTAH, a co. in central Utah, bounded on the n. by Salt Lake co., and containing a portion of the Wasatch range; also Utah lake. The Southern Pacific and the Rio Grande Western railroads intersect, 1986 sq. m.; pop. 1890, 23,768, chiefly of American birth. Co. seat, Provo City.

UTAH LAKE, in Utah co., Utah, 4499 ft. above the level of the sea; 130 sq. m.; 25 m. long, 13 m. wide. It is a body of fresh water without islands, having the Wasatch mts. on the e., the Oquirrh range 10 m. distant, and the Lake and Tintic mts. on the w. Its tributaries flow from the e. It is fed by Corn creek, Hobble creek, the American fork, the Spanish fork, and Provo river. It has an outlet at the n. extremity by the river Jordan, 40 m. in length. It abounds in water-fowl and various kinds of fish.

UTAHS, or UTES, a tribe of American Indians living in Utah, Nevada, Colorado, and New Mexico. They belong to the Shoshone family. Those bands living in Utah were originally friendly to the Mormons, but afterward became hostile. The most important bands are the Yampa, Mohuache, and Capote in New Mexico and Colorado, and the Uintah, Sanpitches, and Pahvants in Utah. The Capotes made a treaty in 1855. The Mohuaches would not help the Mormons fight the United States. In 1865 some of the bands made cession of large tracts of land, agreeing to go on reservations. Black Hawk, chief of the Pah-Utes, fought against the whites, aided by Sanpitch, chief of the Sanpitches, who was arrested, and afterward killed. In 1866 the Mohuaches were defeated by col. Alexander. Rich mineral deposits were afterward found on the Ute reservation in Colorado, and, in accordance with an act of congress in 1872, the reservation Indians ceded 4,000,000 acres.

UTICA, city and co. seat of Oneida co., N. Y.; on the Mohawk river, the Erie canal, and the Delaware, Lackawanna, and Western, the New York Central and Hudson River, the New York, Ontario, and Western, the Rome, Watertown, and Ogdensburg, the Unadilla Valley, and the West Shore railroads; 52 miles e. of Syracuse. The city is built on ground rising from the river to a height of from 410 to 523 feet above sea level; is regularly and handsomely laid out; and has more than a dozen public parks and squares. It is lighted exclusively by electricity, and has several electric street railroads, waterworks belonging to a private corporation, and excellent drainage. Among the noteworthy buildings and institutions are a U. S. government building, state, city, St. Luke's, Homœopathic, and Faxton hospitals, Masonic home, St. Vincent's protectory, orphan asylum, home for the aged, home for the homeless, Y. M. C. A. building, state armory, public library, Oneida co. historical society, young ladies' seminary, academy of the Assumption, conservatory of music, school of music, business colleges, Forest Hill cemetery, and about 50 churches. In 1890 the U. S. census reported for Utica, 565 manufacturing establishments, employing $14,332,510 capital and 12,598 persons. The principal manufactures are men's clothing, cotton goods, boots and shoes, foundry and machine shop products, hosiery and knit goods, cigars, flour and grist mill products, and steam fittings and heat-

ing apparatus. Utica is the center of a noted dairying and hop-growing region, and is one of the largest cheese markets in the United States. There are national, state, and savings banks, and numerous daily, weekly, and monthly periodicals. The city occupies the site of Fort Schuyler, erected at the fording-place of the river about 1758; was settled by colonists from England, and New England after the revolutionary war; was incorporated as a village in 1798; and received a city charter in 1832. Pop. '90, 44,007.

UTICA, an ancient city of Africa, near the bay of Carthage, and a little n.w. of the site now occupied by Tunis. Tradition gives the date of its founding by the Tyrians as 287 years before that of Carthage, of which it was an ally against Rome; but in the third Punic war, Utica, by early submission to Rome, obtained the grant of part of Carthage's territory. The city became prominent during the civil war, for, after the death of Pompey, Cato marched his army there and joined the force under Scipio, Pompey's father-in-law. When Cæsar won the battle of Thapsus, Cato who had remained at Utica tried to reunite the fragments of the defeated army, but, failing in this, gave up all hope of resistance and killed himself. From the circumstance of his death he was surnamed Uticensis. Utica became a free city under Cæsar and it received further concessions from Augustus, but the capital was transferred to Carthage, which was rebuilt and extended by Cæsar and his successor. It was destroyed by the Arabs toward the end of the 7th century. Its ruins lie west of the river known to the ancients as Bagradas. The site of the city was anciently on the shore of the northern part of the Carthaginian gulf and about 27 Roman miles n.w. of Carthage, but on account of changes in the coast-line, caused by the river Bagradas, its site is at present inland.

UTILITA'RIANISM, the name of the peculiar theory of ethics, or of the ground of moral obligation, that adopts, as the criterion of right, the happiness of mankind. The word "utility" was employed, in this acceptation, by Jeremy Bentham; the form "utilitarianism" was first used by John Stuart Mill.

The doctrine of utility is opposed to all those theories that refer us to some internal sense, feeling, or sentiment, for the test of right and wrong; a test usually described by such phrases as a moral sense, and innate moral distinctions. See Ethics. Whence utility is sometimes termed the *external* or objective standard of morality. It is also opposed to the view that founds moral distinctions on the mere arbitrary will of God.

The utilitarian theory has been maintained both in ancient and in modern times, although with considerable variation, not merely in the mode of stating it, but in important peculiarities. Thus, in ancient times, it was held by Epicurus, but in a purely self-regarding form; each person's end was his own happiness exclusively, the happiness of others being instrumental and subordinate. The modern phase of the theory may be said to begin with Hume. He employed, as the leading term of his system, not utility, but benevolence; whereby he gave especial prominence to the disinterested side of moral actions. He strenuously maintained, what must be regarded as the essential feature of the utilitarian doctrine, that no conduct is to be deemed worthy of moral approbation unless, in some way or other, it promotes human happiness; and that actions ought to be visited with disapprobation, exactly according as they have the opposite tendency.

Jeremy Bentham is, more than any other person, identified with the theory of utility, which was, in his hands, not merely the foundation of ethics, but also the basis and justification of political and legal reforms. Having in view the state necessity of sacrificing smaller interests to greater, or, at all events, of not sacrificing greater interests to smaller, he described the ethical end as "the greatest happiness of the greatest number." He illustrated the doctrine by setting it in opposition to *asceticism*, which he interpreted to mean, that pleasure is forfeited, and pain incurred, without yielding a compensating amount of good, either to the agent or to other persons.

Paley advocated a form of utility. He made the will of the Deity, enforced by future rewards and punishments, the impelling motive to duty; but in determining what that will was, in particular cases, he included a reference to the beneficial tendency of actions.

James Mill maintained substantially the views of Bentham. Sir James Mackintosh, while differing in some points from Bentham and from Mill, in the main adhered to utility as the ultimate standard of right. John Austin, in his *Province of Jurisprudence Determined*, has contributed a lucid exposition and a powerful defense of the principle. John Stuart Mill has devoted a separate work to the subject. Samuel Bailey, in his *Letters on the Human Mind*, vol. iii., has discussed the ethical problem fully, and pronounced upon the utilitarian side. Herbert Spencer ranks among the upholders of the theory; and likewise Bain, in his edition of Paley (Chambers's series), and in *The Emotions and the Will*.

Before stating the arguments for and against the principle of utility as the basis of morals, it is proper to inquire what sort of proof an ethical system is susceptible of. Ethics is a practical science (see Sciences), and, as such, involves an end; having the peculiarity of being the final or comprehensive end of all human conduct. See Teleology. Now, in the speculative or theoretical sciences, *ultimate* principles cannot be proved; it is the nature of proof to rest one doctrine on some other doctrine, so that we

must come at last to what is taken without proof; we cannot prove our present sensations; nor can we demonstrate that what has been will be; we must take these things for granted. And so it is with ultimate ends in the practical sciences: we cannot prove that each person should seek his own happiness; we must assume it as an ultimate fact, and trace the consequences. The final end of all conduct cannot be reasoned; it must be gathered from the actual conduct of men; we must find by observation what ends men actually pursue, and, if we can, generalize them into one comprehensive statement. The function of argument in the case is to show where inconsistency has crept in, or to make professions accord with practice. Thus it is that the supporters of utility aver that men, even although refusing the theory, still proceed upon it in their conduct; and that the doctrine cannot be impugned consistently with the admitted motives of human action. Human beings, as a rule, have no other end in life but happiness, either for themselves or for others; and morality belies human nature if it does not accord with this universal object of pursuit.

Although utilitarians hold that good and evil, right and wrong, are properly determined by a calculation of the consequences as regards human happiness, they do not all maintain that past or existing systems of morals have been on all points framed on this principle. Bentham and James Mill appear to have thought that the rule has always been kept in view, though often badly applied. But others, equally earnest in regarding it as the only legitimate rule, are of opinion that, in the past and existing ethical precepts, men have been guided partly by utility, and partly by sentiment—that is, liking or disliking for the act itself, irrespective of any further consequences. Thus, the veneration of the Hindu for the cow, on which ethical duties are founded, is an instance of sentimental liking; the Jewish or Mohammedan prohibition of the pig is a matter of sentimental dislike. In the ceremonial rights of ablution, so widely prevalent, there is a certain show of utility, mixed up with the fancy of cleanliness or purity. In the doctrine of the sacredness of kings, there is a combination of utility and sentiment.

The following are the chief objections to the utilitarian scheme, with the arguments in reply :

I. It is maintained that happiness is not, either in fact or in right, the sole aim of human pursuit; that men actually, deliberately, and by conscientious preference, seek other ends. For example, virtue is an end in itself, to be sought whether it yield happiness or not, and even if it should be productive of the greatest misery. The qualification, however, is always added, that virtue, in the long run, without intending it, and all the more for not intending it, is the unfailing source of happiness.

To which the supporter of utility answers:

1. It is quite true that men seek other ends than immediate happiness to themselves and to others, and that, in particular, they cultivate the virtues as ends in themselves, without always thinking of them as means to happiness. But, then, this is by the operation of a familiar law of the mind, whereby what was originally of the nature of means comes at length to be valued as an end; such is the well-known case of the love of money. The virtues of justice and veracity are essential to human society, just as money represents the basis of subsistence; and by frequent association, the regard that we pay to the end is transferred at last to the means.

2. It may be shown in many ways that the great social virtues derive their worth, in our estimation, from their subservience to human happiness, and not by any absolute title of their own. Take, first, veracity or truth, which, of all the moral duties, has most the appearance of being an absolute and independent requirement. A little consideration will show that even this is not, in our eyes, an unlimited or unqualified virtue. Men have always approved of deception practiced toward an enemy in war, to a madman, or a highway robber; also secrecy or concealment, even although misinterpreted by others, is generally allowed—unless it leads to some pernicious results; while, if the divulgence of truth were attended with harm, it would be universally reprobated. But an absolute standard of truth is incompatible even with secrecy or disguise; in departing from the course of perfect openness, or absolute publicity of thought and action, in every possible circumstance, we renounce ideal truth in favor of a compromised, qualified veracity—a following of truth only so far as is expedient.

Again, as regards justice, the presence of considerations of utility is equally obvious. There is no absolute rule of justice that does not bend to circumstances. If justice be defined, giving every one his own or what he is entitled to, there is the show of an absolute rule; but, in reality, nothing is determined. The meaning is to give to each what *law* and *custom* have declared to be a man's own. It is declared just for an elder son to receive a larger share of the parental estate than all the rest of the children put together; but it is clear that whatever justice there is in this must be founded on some ground of expediency. (See on this subject, J. S. Mill's *Utilitarianism*, chap. v.)

II. It is further objected to the adoption of utility as the standard of right, that the full consequences of actions are too numerous, involved, and complicated to be reduced to calculation; and that even where the calculation is possible, people have seldom time to make it.

To this it is answered, first, that the primary moral duties refer to conduct that can be fully calculated to the satisfaction of any reasoning mind. Thus, to revert to the

two leading examples, truth and justice: the habitual disregard of these duties would soon bring a society to utter confusion and ruin; without them there could be no social co-operation; man would fall below the condition of the gregarious animals; the race could hardly be saved from extirpation. On the other hand, the observance of these duties, in a high degree, raises to a corresponding degree the means of human happiness. The balance of advantages is all on one side—there is no case for the other side at all.

There have always been moral rules or enactments where the calculation of consequences was much less easy; for example, the indissolubility of marriage is maintained in some countries and not in others; and there have been considerable differences as to the forbidden degrees of affinity in marriage. In these usages there are both advantages and disadvantages, and the preponderance is variously estimated by different calculators. In such cases the utilitarian would say: Do not make a compulsory enactment restricting liberty, which restriction is an evil in itself, unless the balance of advantages is unquestionable and great.

As to the argument that it is impossible to make the calculation of consequences every time we perform a moral act, the reply is, this is unnecessary; the calculations as to the various duties have been already made, and are embodied in rules, which rules we remember and apply without thinking of the process gone through in arriving at them. The navigator at sea does not need to compute the *Nautical Almanac* every time he determines his longitude; he carries it to sea with him ready for use.

III. A third objection is that men in all ages have distinguished between the right and the expedient, that is, the useful; the two are in most languages put in opposition or contrast. The reply is that the expedient, when thus opposed to the right, commonly means what is expedient for the agent at the time, but is not expedient for people generally, or even for himself in the long run. It is sometimes expedient, in this sense, to tell a lie, to rob, or to murder; but such actions are not expedient in the sense of general utility, or the greatest happiness of mankind.

It is further to be remarked in this contrast of the expedient and the right, that the expedient may mean simply an addition to our conveniences or comforts, something that it is well for us to have, but that we might do without. Thus it is highly expedient to possess cheap postage, railways, and electric telegraphs. On the other hand, the right points to the essentials of our existence; without the fulfillment of contracts, respect to life and property, obedience to law, society would be dissolved. The distinction was expressed in one of Cromwell's speeches, by the contrast of a nation's being and its well-being; what secures the one is emphatically the right, the promotion of the other is the expedient. Right is the highest and most imperative form of expediency.

IV. A fourth objection against the utilitarian scheme is that all useful things are not made obligatory; it may be useful to have railways, but it is not a duty of every man to make them. But the utilitarian, while contending that nothing should be made a moral duty but what contributes to the happiness of mankind, does not hold the converse, that whatever promotes human welfare is a moral duty.

So much for the objections. The positive ground of utilitarianism is that men actually recognize happiness as their paramount consideration, or highest end. This, as a general rule, is too obvious to require proof. Each one's plan of life is principally made up of ideas of happiness to self or to others. All our good wishes to one another are repetitions of the one idea, "May you be happy." The seeming exceptions have been noticed above.

One of the strongest confirmations of the doctrine is derived from the usual inducements to right conduct, common to all moralists. We find that no one can preach morality without making use of its bearings upon happiness. The very meaning of the terms expressive of the highest virtues—love, goodness, mercy, compassion, fidelity, honesty, integrity, justice—is something that relieves the pains and augments the pleasures of sentient beings. To love is to make the object happier, and love is the fulfilling of the law.

Although there be duties occasionally imposed upon men that have no obvious tendency to increase happiness, but rather to diminish it, as the labors of some cumbrous ceremonial system like Hinduism, those duties have to be upheld by the fear of punishment or the hope of reward, still testifying to the predominating motives of the human mind. It is not, however, by reference to traditional observances that the happiness motive is most clearly tested. The proper plan, as remarked by Mr, Samuel Bailey, is to try it upon some fresh case, some entirely new enactment, when it will be found that the interest or happiness of the community is the *sole* consideration appealed to. If a new law of inheritance is proposed, or a new government board constituted, nobody advances any other criterion but expediency, or the good of certain persons now or in the future; unless such expediency can be shown, no one will move in the matter at all; and the earnestness of the promoters will be in exact proportion to their sense of the resulting good. We may, through blind conservation, keep up usages not only destitute of utility, but productive of harm; but we should not now deliberately set up for the first time any practice that we did not regard as conducive to somebody's well-being. Traditional associations excepted, the strength of our approbation or disapprobation always follows our estimate of happiness or misery produced.

It is worthy of remark that utility, or the promotion of human welfare, as it is the very meaning of the work of a public benefactor, expresses the sum of the labors of all the best men that have ever lived.

UTO'PIA (Gr., *ou*, not; and *topos*, a place, equivalent, therefore, to "Nowhere") is the name given by Sir Thomas More (q.v.) to the imaginary island which he makes the scene of his famous political romance, *De Optimo Respublicæ Statu, deque Nova Insula Utopia* originally published in Latin, at Louvain, in 1516, and translated into English by Bishop Burnet. This island, which More represents as having been discovered by a companion of Amerigo Vespucci, is the abode of a happy society, which, in virtue of its wise organization and legislation, is free from the harassing cares, inordinate desires, and customary miseries of mankind. More's romance obtained a wide popularity, and the epithet *utopian* has since been applied to all schemes for the improvement of society which are deemed not practicable—e.g., to those of St. Simon (q.v.) and Fourier (q.v.). Everything, however, is not utopian that is called such. All the great changes that have taken place in the world have had to pass through a "utopian" phase.

U'TRAQUISTS (Lat. *utraquistæ*, from *utrâque*—i.e., *specie*, in both kinds), a name at first given to all those members of the western church, in the 14th c., principally followers of John Huss, who contended for the administration of the eucharist to the laity under both kinds; but in later times restricted to one particular section of the Hussites, although all the members of that sect alike claimed this as a fundamental principle of their church discipline. The name may be said to date from 1415, when the followers of John Huss, in Prague, and elsewhere in Bohemia, adopted "The communion of the cup" as their rallying cry, and emblazoned the cup upon their standards, as the distinguishing badge of the association. In 1417 the university of Prague, by a formal decision, directed that all the laity should communicate in both kinds; and the council of Constance, in consequence, prohibited students from any longer resorting to Prague for the purposes of study. The Hussite party, on the contrary, made the demand one (the second) of the four points upon which they insisted as the condition of their submission to the church. Their demands were rejected by the council of Constance; but the council of Basel, in 1433, acceded to the demand for the cup, under the condition that, whenever communion was so administered, the ministering priest should accompany the ministration with a declaration that Christ was contained whole and entire under each species. A portion of the Hussite party was content with the explanation of this and the other points offered by the council, but the more violent held out. See Huss. The former were called Utraquists, and continued to be so designated. During the reformation troubles, this division was still maintained. The Utraquists were favorably regarded by the imperial party; and after the battle of Mühlberg, in 1547, they alone were formally tolerated in Bohemia and Moravia. One of the most celebrated leaders was Jacobus v. Mies. The name Utraquist is still applied to certain districts or villages in Bohemia and Moravia; but it is used not in reference to this theological controversy, but merely to convey that, in these villages or districts, *both languages*, Bohemian and German, are spoken.

U'TRECHT, a province of the Netherlands, bounded on the w. by South Holland, n. by North Holland and the Zuyder Zee, e. by Gelderland, and s. by the Rhine and Leck. It is 42 m. from e. to w., and 21 from n. to south. The chief places are Utrecht, Amersfórt, Rhenen, Wijk bij Duurstede, Montfórt, and Ijsselstein (pronounced I'sselstein), and about 40% of the population are urban residents. Area, 534 sq. m. Pop. '95, 238,282; rather more than 30 per cent. are Roman Catholics; the remainder are Protestants.

The country is varied by beautiful hilly districts, level fields, orchards, tilled land, meadows, and moss. The hilly tract stretches from near Amersfórt to Rhenen on the Rhine, 21 miles. It is well wooded. Rye, oats, and buckwheat are sown; sheep, cattle, and bees extensively kept. To the s. of this belt is rich clay land, producing excellent wheat and barley. Near Amersfórt and Rhenen, tobacco is largely planted.

Utrecht is watered by the Rhine, Vecht, Leck, Amstel, Grebbe, and many other rivers. The inland fishing is trifling; but many herrings, eels, flounders, anchovies, etc., are taken in the Zuyder Zee. Besides agriculture, the industries are soap-boiling, sawing wood, copper and iron founding, making machinery, carpets, tiles, bricks, coarse pottery, cement, etc. There are many beautiful country seats, the climate being dry and healthy.

UTRECHT (*Utrajectum*, or *Trajectum ad Rhenum*), the provincial capital, is beautifully situated in the midst of a district composed of sand-hills, woody heaths, rich grassy meadows, extensive orchards, flower-gardens, and cultivated fields. It lies 23 m. s.s.e. from Amsterdam. When the census was taken (1880), the pop. numbered 67,633; at the end of 1895 it was 94,305. The broad walls have been leveled, planted with trees, and formed into beautiful and well-kept promenades.

Utrecht is favorably situated for trade, being the point from which several railways radiate, and having excellent water-communication by the old Rhine and the Vecht. The staples are grain, cattle, and various manufactures. It is the residence of many noble families, the seat of a university with an observatory, botanical gardens, a chemical

laboratory, and museums. Principal buildings are the cathedral or Domkerk, the town-house, the mint, the university, and several handsome barracks for the infantry and cavalry, especially the Willemskazerne. The cathedral was consecrated to St. Martin about 720. In 1674, a hurricane destroyed the body of the building between the choir and the tower, so that the latter (321 ft. high) is now isolated. The famous university of Utrecht, founded in 1636, numbers about 750 students, and has a good library of 200,000 volumes. Utrecht has been for centuries the headquarters of the Jansenist church (see JANSEN). There is a national school for military surgeons; a grammar-school; normal school for teachers; a musical college, for elementary singing, the piano, and violin; a historical society; meteorological institute; medical society; pharmaceutical society, etc. Education generally stands high.

The charitable institutions are numerous. Principal industries are—manufacturing tobacco and cigars, woolen fabrics and carpets, making salt, furniture, baskets, tin, copper, and silver work, sawing wood, rope-making, iron-founding, book-printing, the manufacture of organs, etc.

Utrecht is one of the oldest cities of the Netherlands, and probably was founded by the Romans. Here the famed union of the northern provinces for the defence of political and religious freedom was formed Jan. 23, 1579. For a short time in 1807, Louis Napoleon, king of Holland, resided in Utrecht. It has been the birthplace of many distinguished men, among others Pope Adrian VI., in 1459.

Utrecht has acquired a degree of celebrity for the treaties there concluded, which brought to a close the war of the Spanish succession. See SUCCESSION WARS. After this disastrous conflict had endured for more than 10 years, Great Britain, finding that the reasons which had prompted her to engage in it no longer existed, tried to induce Austria to come to terms with France, but failing in this, at once signed private preliminary articles for herself, Oct. 8, 1711. On Jan. 12, 1712, a congress was opened at Utrecht; and France, desirous, at almost any price, of detaching Britain from the grand alliance, voluntarily made so many concessions, that the latter had only further to demand the banishment of the elder pretender, whose sojourn in France had been a source of disquietude, the conclusion of a treaty of commerce, and indemnities for her allies—all which points were at once conceded. But the preposterous demands of Austria, which included not only the renunciation by the Bourbons of the entire Spanish empire, but the restoration of all those places which had been ceded to France by the treaties of Münster, Nimeguen, and Ryswick, and the retention of all Austria's conquests in Italy, the Low Countries, and Spain, forced the French to break off the conferences, in the hope of making a separate peace with Britain, and compelling the other allies, by negotiation or arms, to lower their pretensions. This plan was successful; agreement on all points at issue was established between France and Britain in Aug., 1712; and arrangements were also come to with Holland, Portugal, Prussia, and Savoy soon afterward. As each of the contracting parties negotiated in its own name, no fewer than nine distinct treaties of peace were signed in the following spring, April 11, 1713. By the treaty between France and Britain, the former ceded St. Kitt's, Hudson bay, Nova Scotia, and Newfoundland (the liberty of fishing for cod being reserved), recognized formally the reigning dynasty and the Hanoverian succession, agreed to demolish the fortifications of Dunkirk, engaged that the crowns of France and Spain should never be united, and that no part of the Spanish Netherlands should ever be ceded or transferred to France; and Spain renounced her Italian possessions in favor of Austria, and gave up Gibraltar and Minorca to Britain, with which power she also concluded the *assiento* (q.v.) treaty. The chief of the special agreements with the other contracting parties were as follows: Ypres, Knocke, etc., to be exchanged with Holland for Douai, Bouchain, etc., and a treaty of commerce to be concluded; both banks of the Amazon to belong to Portugal; Spanish gelders and the district of Kessel, to be ceded to Prussia, and its ruler's title of king, assumed in 1701, formally recognized, Prussia in turn resigning all claims to the principality of Orange; the duke of Savoy to obtain Sicily, with the title of king, etc. The treaty of Utrecht did not made peace with Austria and the German empire; but in the following year, at Rastadt and Baden, they agreed to substantially the same terms as were proffered at Utrecht. The electors of Cologne and Bavaria, who had been put under the ban of the empire, were restored; Sardinia, granted to Bavaria at Utrecht, was restored to Austria; Austria renounced her claims to the Spanish succession; the cession of the Spanish possessions in Italy was confirmed; Breisach and Freiburg, in the Breisgau, were also given to Austria; the highest ridge of the Maritime Alps was made the boundary between France and Savoy; and on failure of the Spanish Bourbons, the crown of Spain was to fall to the house of Savoy.—See Lord Mahon's *History of the War of Succession in Spain* (Lond., 1832); Gerard's *History of a Great Treaty.*

UTRE'RA, an old t. of Spain, in the province of Seville, and 18 m. by railway s.e. of the city of that name. In early times, it was flourishing and populous; but fell into a state of stagnancy, from which it has begun to revive along with the rest of Spain. It is important as a military post, contains a beautiful Gothic church, a Moorish castle, and cavalry barracks. The streets and promenades are kept clean and fresh by streams of running water. Utrera contained, '87, 15,010 inhabitants, mostly agriculturists engaged in the productive estates which surround the town. Corn, wine, oil, soap, pottery, and

fruit are produced. Sheep and cattle, as well as a breed of fierce bulls, are reared in the vicinity.

U'TRICLE is the botanical term for a kind of seed like the achenium (q. v.). In the utricle, however, the pericarp does not lie close to the seed, but surrounds it as a loose inflated covering.

UTRICULARIA. See BLADDERWORT.

UTTERING COUNTERFEIT COIN is an offense punishable with one year's imprisonment with hard labor. The punishment is increased if, besides uttering, the person has other counterfeit coin in his possession. It is also an offense to utter false foreign coin as the U. S. coin or as foreign coin.

UTTOX'ETER, a market-t. of Staffordshire, on an eminence above the vale of the Dove, 16 m. n.e. of Stafford. Its church with an ancient tower and lofty spire is a noteworthy building; and the town contains a Latin school. There are iron works and cork manufactures. Pop. '91, 5516.

UVAL'DE, a co. in s.w. Texas, consisting of level, fertile plains; 1420 sq. m.; pop. '90, 3804—chiefly of American birth, with colored. Co. seat, Uvalde.

U'VULA. See PALATE.

UWINS, THOMAS, 1782–1857; b. England; educated for the profession of an engraver, but became a painter in water-colors and oils. His pictures were mostly of Italian scenes, and among the most popular were: "Dressing for the Festa," "The Fisherman's Song of Naples," and "Interior of a Saint Manufactory at Naples."

UXBRIDGE, a market-t. in the co. of Middlesex, on the Colne, 18 m. n.w. of the city of London. Pop. '91, 8206. Its corn market is one of the most important in the kingdom.

V

V, THE twenty-second letter in the English alphabet, is derived directly from the Lat. character *v*, which represented originally both the consonant *v* and the vowel *u* (see U). The name of the letter is derived from the Phenician and Hebrew *vau* (signifying a nail, which the form of the letter originally resembled), which stood sixth in the alphabet, and became the digamma (q.v.) of the old Greek, and the *f* of the Latin (see F). The Greek *υ* (see ALPHABET), from which the Lat. *v* is taken, had, in the classical period, degenerated into a sound like the French *u*, and in modern Greek is undistinguishable from *i*. The Greeks, after they had lost the digamma, represented Lat. *v* by *ου* or *β*; e.g., *Ουαρρων* or *Βαρρων* = Varro, *Βιργιλίος* = Virgilius. In the beginning of Latin words, *v* must have had a consonantal sound approaching that of *v* in English, as is inferred from its persistence as compared with the Greek digamma; e.g., Vinum = (Ϝ)*οἶνος*, Vesta = *Ἑστία*. Between two vowels, on the contrary, it was often dropped out, as in *nuper* for *novumper*, *Jupiter* for *Jovipiter*, *prudens* for *providens;* from which we may conclude that it had in that position the power of a semivowel, like Eng. *w*. In new high German, *v* takes the place of Gothic and Eng. *f* (see F), and is pronounced like *f*, while the *v*-sound is expressed by *w*.

VAAL RIVER, the Dutch name of one of the most important branches of the Gariep or Orange river, and signifying yellow, from the color of its waters when in flood, its Hottentot name, Ky Gariep, having really the same signification; the Betjuans call it Namagari. It rises in the Drakenberg range, at the n.w. angle of Natal, and running a very circuitous course of about 500 m., forming the boundary between the Orange River Free State and the Transvaal on the other, joins the other great branch, the Nu Gariep or Orange river, in lat. 29° 10′ s., long. 24° 15′ east.

VACATION, in legal language, means the holiday usually enjoyed by lawyers in consequence of many of the courts being closed, and thereby some steps in a suit not being competent during part of the autumn of each year. There are short vacations during other parts of the year; but the long vacation is that which extends from Aug. 10 to Oct. 24, and during that part of the year it is usual for legal business to be in great measure suspended.

VACCINATION is the process by which a specific disease, termed *vaccinia*, or cow-pox (from the Latin word *vacca*, a cow), is introduced into the human organism with the view of protecting it against an attack of an incomparably more severe disorder—viz., small-pox. For the history of this remarkable discovery of vaccination—"that master-piece of medical induction"—we must refer to the life of Jenner (q.v.). In his *Inquiry into the Causes and Effects of the Variolæ Vaccinæ*, published 1798, he established the following facts: (1) That this disease casually communicated to man has the power of rendering him unsusceptible of small-pox; (2) that the specific cow-pox alone, and not other eruptions affecting the cow, which might be confounded with it, had this protective power; (3) that the cow-pox might be communicated at will from the cow to

man by the hand of the surgeon, whenever the requisite opportunity existed; and (4) that the cow-pox once ingrafted on the human subject, might be continued from individual to individual by successive transmissions, conferring on each the same immunity from small-pox as was enjoyed by the one first infected direct from the cow.

The *method of vaccinating* and the *phenomena of cow-pox*, as observed in the human subject after vaccination, claim our first and chief attention. Except under circumstances of special risk (as, for instance, where small-pox is in the neighborhood), children should only be vaccinated when they are in apparently good health. Diarrhea and skin diseases are especially to be avoided; and it is important to see that there is no chafing behind the ears, or in the folds of the neck or groin. As more than one-fourth of the whole number of deaths from small-pox in England during the six consecutive years 1856–61, took place in children of less than one year, it is obviously expedient that children should be vaccinated in very early infancy, provided health permits. Dr. Seaton, in his comprehensive article on this subject in Reynold's *System of Medicine* (1866, vol. i. p. 489), observes that "plump and healthy children living in large towns should be vaccinated when a month or six weeks old; in more delicate children, the vaccination might be postponed till they are two or three months old; but all, except those whose state of health positively contra-indicates vaccination, should be vaccinated by the age of three months." This early age has also the advantage of being free from the irritation of teething.

The lymph to be used should always be taken from a healthy child, and from thoroughly characteristic vesicles; and when lymph in all respects satisfactory cannot be procured as is often the case in country districts, the operation should be postponed. Lymph is usually taken when the vesicle is fully formed, which is usually about a week after vaccination; if it is not taken till the areola (which will be presently described) is complete, its protective power is far less certain. "Prime lymph," says Dr. Seaton, "has always a certain degree of viscidity; and a thin serous lymph, even from a vesicle which is not advanced, is to be avoided. Babies are much better lymph-givers than elder children or adults; and children of dark complexion, not too florid, with a thick, smooth, clear, skin, yield the finest and most effective lymph." Lymph should always, if practicable, be passed direct from arm to arm; and preserved lymph should only be had recourse to when a vaccinated child cannot be obtained. A good vesicle freely punctured on its surface exudes enough lymph or vaccine matter for the direct vaccination of five or six children, and for charging six or eight ivory points for future emergencies. The process of vaccination consists essentially in introducing the lymph into the structure of the true skin, or in bringing it in contact with the absorbing surface. This may be effected in various ways, one of the most common being by puncture. As the operation is extremely simple, and the knowledge of the mode of performing it may prove not only interesting but generally useful, we shall briefly describe it. The skin on the outside of the arm, below the shoulder, should be held upon the stretch, and a very sharp, clean lancet, well charged with lymph, should be made to puncture the skin from above downward, at an angle of about 45°, and be made just to enter the true skin. The matter thus inserted is retained by the valvular character of the puncture and the elasticity of the skin. In this form of the operation, not less than five or six such punctures should be made, at a distance of half an inch from the other; and for the sake of security, three punctures may be made on each arm. If the lymph is preserved on points, each point, after being held in the steam of hot water so as to dissolve the lymph, should be inserted into the punctures made by an ordinary lancet. Some surgeons make a number of minute superficial punctures over a patch of the size of a ten-cent piece, and spread the lymph over this spot with the flat part of the lancet: this kind of tatooing should be repeated on three spots. Others make a number of parallel scratches, or crossed scratches, with a charged lancet; and others, again, use special scarifiers or rakes, consisting of three or four needle-points inserted in an ivory handle; and drawn either once or again at right angles over the tense skin, the lymph being then plastered over the scarified surface. Of these various plans, Dr. Seaton believes that the best marks and most successful treatment result from this last plan of cross scratches. A far better plan of preserving lymph than that of drying it on points, is that of preserving it in a fluid state in carefully closed capillary tubes, in which form it is ready for use without any preparation. When the operation is successfully performed, the skin at the spot becomes slightly elevated, hard, and red on the third or fourth day; on the fifth or sixth day a vesicle of a blueish-white color forms, which presents an elevated edge and a depressed cup. It is distended with clear lymph, and attains its perfection on the eighth day; and now, or on the ninth day, the vesicle is surrounded by an inflamed ring or areola; on the ninth, tenth, and eleventh days the vesicle becomes a pustule, the cupped form disappears, the areola enlarges till it becomes a circle, with a diameter of from one to three inches. On the twelfth, thirteenth, and fourteenth days the pustule dries up; and in the course of the next week the scab separates and falls off; it seldom remains so long as the twenty-fifth day. It leaves a cicatrix, which commonly is permanent in after-life, circular, somewhat depressed, dotted or indented with minute pits, and in some instances radiated. The establishment of the areola is accompanied with constitutional disturbances, as indicated by restlessness and heat of skin, frequent derangement of the stomach and bowels, and occasional swelling of the glands of the

arm-pit. These symptoms are seldom severe, but seldom quite absent. We occasionally meet with cases in which the course of the above symptoms is modified, as when they are simply retarded, or simply accelerated, or altogether irregular and spurious; and it should be carefully borne in mind that "a vaccination presenting any deviation from the perfect character of the vesicle and the regular development of the areola, is not to be relied on as protective against small-pox."—Seaton, *op. cit.* As a general rule, neither the local nor the constitutional symptoms of ordinary vaccination require any treatment

From investigations conducted some years ago by the English government, and published in several of the *Reports of the Medical Officer of the Privy Council*, it appears that amongst the poorer classes, vaccination is often so imperfectly performed as to leave no mark, and to exert no protective power. Experts in the subject believe that with good lymph, and the observance of all proper precautions, a good vaccinator should not fail of success in his attempts to vaccinate above one in 150 cases; while Dr. Seaton puts one failure as a fair proportion in 170 cases.

The official inquiries above referred to, in the course of which the arms of nearly half a million vaccinated children were examined, prove, says Dr. Seaton, who was employed in the investigation, the great extent to which imperfect or insufficient vaccination has obtained: taking the country throughout, not more than one child in eight was found to be so vaccinated as to have the highest degree of protection that vaccination is capable of affording; and not more than one in three could, on the most indulgent estimate, be considered as well protected. The main causes of this imperfect success were the following: "(1) The frequency with which practitioners, instead of attempting fully to infect the system, had been satisfied with insertions of lymph sufficient to produce only one, two, or three ordinary vesicles; (2) the want of due attention to the *selection* of the lymph used in vaccinating; (3) carelessness and clumsiness in the performance of the vaccination, so that, if the operation did not wholly fail, it very frequently resulted in a less degree of effect than it had been the aim of the operator to produce; and (4) the great and unnecessary extent to which the use of preserved and conveyed lymph was substituted for vaccination direct from the arm."—Seaton, *op. sit.*, p. 503. The following observations made by Drs. Buchanan and Seaton during the epidemic of small-pox in London in 1863, on upwards of 50,000 children in various national and parochial schools, workhouses, etc., are of such extreme importance that we make no apology for inserting them. Some of the children had never been vaccinated; the large majority had been vaccinated in various manners and degrees. Of every 1000 children without any mark of vaccination, no fewer than 360 had scars of small-pox; while of every 1000 children who had evidence of vaccination, only 1.78, on an average, had any such traces: and with regard to the quality and amount of the vaccination, it was found that, of children having four or more cicatrices, only 0.62 per 1000 had any trace of small-pox; while of those who had a single bad mark, 19 per 1000 were scarred by small-pox. Hence the best vaccination was more than 30 times as protective as the worst, and the worst was more than 47 times better than none at all. The importance of the completeness of the vaccination, as shown by the cicatrices, is also well shown by the results obtained by Mr. Marson. From the study of more than 15,000 cases at the small-pox hospital, he finds that while the unvaccinated died at the rate of 37 per cent, the vaccinated have died at the rate of only $6\frac{1}{2}$ per cent; the mortality among those with four or more scars being only 0.55, while that among those with only a single scar was 7.73 per cent; so that, while the average risk which vaccinated persons run if they do catch small-pox is about $\frac{1}{6}$ of the risk run by unvaccinated persons, well-vaccinated persons run less than $\frac{1}{70}$ part of the risk. It must further be borne in mind that, while few unvaccinated persons do not at some period of life sustain an attack of small-pox, the cases are comparatively rare in which a well-vaccinated person catches the disorder; so that the protective power of vaccination shows itself in two ways, viz.: (1) in shielding the constitution, in the great majority of cases, from any kind of an attack of small-pox; and (2) in the exceptional cases, of so modifying the disease as almost invariably to deprive it of danger to life, or of those terrible disfigurements which the unmodified disease so frequently leaves behind it.

With regard to the subject of *re-vaccination*, it has been amply demonstrated that its utility and necessity stand upon no speculative reasoning, but upon the broad basis of experience and observation. This operation should be performed with the same care and pains as primary vaccination, nor should it be left to periods when small-pox is epidemic, but should be performed on all persons after puberty, and this is the more necessary for the primary operation is often very imperfectly performed. During an epidemic of small-pox, even young children, if the marks of the primary vaccination are at all imperfect, should most decidedly be re-vaccinated. In re-vaccinating it must always be remembered that "the local results of re-vaccination of any individual give us absolutely no information whatever as to the constitutional condition in which the re-vaccinated person was with regard to the liability to contract small-pox."

Much has been written regarding the *dangers of vaccination;* and the well-known Rivalta case, in which an infant thus communicated syphilis to a whole population in a remote district of Piedmont (see Syphilis); and the death some years ago of a distinguished middle-aged baronet from (as it was alleged) vaccination with impure lymph, have directed special attention to the subject. For the discussion of this subject we

must refer to Creighton's *Jenner and Vaccination* (1888) and Hart's *Truth about Vaccination* (1880), and we will only remark that those who have had most to do with vaccination, and those who have had the most extensive experience in the diseases of children, concur in the belief of the non-communicability of disease by this operation.

The relations between small-pox in man and cow-pox in the cow, claim a passing remark. Jenner believed that they were essentially the same disease, and that they had a common origin in the grease of the horse. Various experiments have been made to inoculate healthy cows with small-pox, and those of Mr. Ceely, of Aylesbury, in 1839 and of Mr. Badcock, of Brighton, in 1840, who induced vesicles by inoculating cows with small-pox virus, and thus obtained a supply of genuine vaccine lymph, place the identity of the diseases beyond all question. The disease really known as grease appears to have nothing to do with cow-pox or small-pox; but the horse occasionally suffers an affection which is precisely the same as the small-pox in man and the cow-pox in cows; and the lymph from this horse-pox has been successfully used. See GERM THEORY.

Much has been done in this country within a few years in the matter of compulsory vaccination. Massachusetts passed laws to regulate vaccination as early as 1809, affixing a penalty of $5 for neglect to comply with regulations. A few years later several other states had followed her example, and in Rhode Island the penalty was a maximum fine of $50 or imprisonment for thirty days. Massachusetts also organized a State Board of Health in 1854, and similar organizations are now (1891) to be found in seventeen states. These, by the co-operation and aid of the National Board of Health, have adopted a set of rules and regulations by which the matter of contagious diseases are, at least, partially controlled. In Jan., 1882, the National Board issued a circular to the heads of the various departments for the vaccination or revaccination of all employés in those departments, and this was very generally complied with. But the most efficient work was done at this time by the Illinois State Board of Health, by which 233,340 vaccinations were performed in a population of over 3,000,000 people. Vaccination, however, is very largely under the control of local Boards, who have full authority to act, and this is frequently done by the Town Board acting in unison with the School Board, and excluding all unvaccinated children from the schools. See Edwardes, *Vaccination and Small-Pox* (1892).

VACCINIA'CEÆ, a natural order of exogenous plants, differing from *ericeæ* chiefly in having an inferior ovary and succulent fruit. Many botanists make it a section of *ericeæ*. About 200 species are known, natives of temperate climates, in all parts of the world, but chiefly in the northern hemisphere. A few species, remarkable as being parasitic, are natives of Peru. The vacciniaceæ are shrubs, and rarely small trees, with numerous round or angular branches, simple leaves on very short stalks, and flowers solitary or in racemes. Whortleberries and cranberries (q.v.) are the most familiar examples of the order. See HUCKLEBERRIES.

VÂCH (literally, speech) is another name of saraswatî (q.v.), the female energy of the Hindu god Brahman.

VACHASPATI (literally, "lord of speech," from the Sanskrit *vâch*, speech, and *pati*, lord) is, in Hindu mythology, one of the usual names of *vrihaspati* (q.v.), the instructor of the gods.

VACHEROT, ÉTIENNE, b. France, 1809; studied at the normal school in Paris; professor there, 1833; succeeded Cousin at the Sorbonne, 1837–51, but was suspended through ultramontane influence; was dismissed, 1852, for refusing to take the oath to Napoleon III., and imprisoned 3 months for his treatise *La démocratie*, and disfranchised till 1870; elected to the national assembly, 1871. He published *Histoire critique de l'école d' Alexandrie; La Métaphysique et la Science; Essais de Philosophie critique; La Religion.*

VACUUM literally means empty space, or space wholly devoid of matter. From Aristotle to Descartes, metaphysical speculators took the question into their own hands, and, of course, wrote nonsense about it. Thus, Descartes commits the absurdity of saying that, if a vessel be perfectly empty, its sides must be in contact—confounding the totally distinct ideas of *matter* and *space*. The dictum that *nature abhors a vacuum*, was employed to account for the rise of water in pumps; but it was presently found that nature did not abhor a vacuum through more than an elevation of about 32 feet. See TORRICELLI. When the subject was taken up by its legitimate owners, the experimental philosophers, such absurdities disappeared, but real difficulties were detected. So far as experiment has yet guided us, we may assert that vacuum cannot exist. The interstellar spaces, though probably devoid of ordinary ponderable matter, or at best only occasionally visited by it, are certainly pervaded by the luminiferous medium. See ÆTHER, UNDULATORY THEORY, that this is matter (q.v.), is amply proved by the effects of its vibrations on the eye, and by the resistance which it has been discovered to oppose to the motion of Encke's comet. It is not merely for the propagation of light and heat that we are forced to assume that the universe is a *plenum;* Newton expressly said (see FORCE, where the quotation is given at greater length) "That gravity should be innate, inherent, and essential to matter, so that one body may act upon another at a distance through a *vacuum*, without the mediation of anything else, by, and through which their action and force may be conveyed from one to another, is to me so great an absurdity, that I believe no man who has in philosophical matters a competent faculty of thinking can ever fall into it." Nothing could be stronger than this; and we have in addition, the results of

modern observation, which show a connection between sun-spots, planetary configurations, and terrestrial magnetism, obviously requiring some material channel to exist between the sun and its secondaries. Faraday's electrical discoveries tend to the same conclusion.

But, in ordinary language, a vacuum is said to be produced (more or less *perfect*) when ordinary ponderable matter, such as air, is more or less completely removed from the interior of a closed vessel. Till the commencement of the present century, the most perfect vacuum that could be obtained was what is called the Torricellian vacuum—i.e., the space above the mercury in a carefully filled barometer-tube. Such a vacuum, however, is almost useless for experimental purposes, and, besides, it contains mercurial vapor.

A suggestion of Davy's, recently re-invented and greatly improved by Andrews, gives the means of procuring a much more perfect vacuum than the Torricellian. An ordinary air-pump removes all but about the $\frac{1}{120}$ of the gas in the receiver—i. e., produces a vacuum of about $\frac{1}{4}$ inch, as it is called. But if the gas employed be carbonic acid, admitted and pumped out several times, so as to get rid, as far as possible, of the last trace of air, the remaining gas will be almost wholly taken up by means of moistened caustic potash previously placed in the receiver. Concentrated sulphuric acid should also be present to desiccate the potash when it has done its work. In this way, Andrews easily obtained a vacuum of abt. $\frac{1}{1500}$ of an inch, which remained unchanged for a fortnight. Here all but $\frac{1}{1850000}$ of the air had been removed. Further improvements, devised by Frankland, Gassiott, and others, have been made in this process, especially for the production of (so-called) vacuum-tubes for the study of electrical discharges; and the exhaustion has been sometimes carried so far that the attenuated matter remaining was unable to conduct the discharge of an induction-coil.

VADE MECUM is a Latin expression meaning literally *go with me*, and is used to designate anything that a person considers so indispensable as to carry it constantly with him, e.g., a book or a field glass.

VAGA, Perino del, or Pietro Buonaccorsi, 1500–47; b. Florence; went to Rome; was employed by Raphael on designs in fresco for the Vatican; became greatly distinguished as a painter after the death of Raphael; was imprisoned during the sack of Rome, 1527; when released he went to Genoa; returned to Rome during the pontificate of Paul III. His style of design was that of Michel Angelo, and he excelled in classical and religious subjects: his finest work is the "Creation of Eve," at Rome.

VAGRANTS, or Tramps. See Beggars.

VAHLEN, Johannes, a renowned and cultured philologist, was born in Bonn in 1830, where he studied, and, after a brief connection with the gymnasium of that place, entered the university in 1854. In 1856 he was made professor in Breslau, 1858 at Freiburg and Vienna, and since 1874 in Berlin as successor to Moritz Haupt. As a pupil of Ritschl he was at first occupied with the remains of ancient Latin poetry, but later with Roman prose-writers and with Aristotle. Among his writings in the former line are to be noted especially: *Enniancæ poesis reliquiæ* (1854), *Cn. Nævii de bello Punico reliquiæ* (1854), an essay on the *Menæchmi* of Plautus (1882), *Ueber die Annalen des Ennius* (1886). In the second department the edition of *Fragmente des Ulpian* (1856), and the *Cicero de legibus* (1871); then numerous essays on Aristotle, in the *Proceedings of the Vienna Academy*, later a critical edition *der Aristotelischen Poetik;* and many articles in periodicals, among them a treatise on *Laurentius Valla*, whose *opusculatria* he edited. For a number of years he was co-editor of the periodical, *Hermes*, and also of the *Zeitschrift für oesterreichische Gymnasien.* Vahlen is a scholar of taste and fine discrimination.

VAIL, Thomas Hubbard, s.t.d., ll.d., b. Richmond, Va., 1812; graduated at Trinity coll., Conn., 1831, and at the Gen. theol. sem., 1835; was ordained priest in the Prot. Epis. church, 1837; held positions in Philadelphia, and in Worcester, Cambridge, Essex, and Taunton, Mass., in Westerly, R. I., and in Muscatine, Iowa. He was consecrated bp. of Kansas, 1864. He wrote *The Comprehensive Church*, *Life of Lyde*, etc. D. 1889.

VAIR. See Heraldry.

VAIS'ESHIKA is the name of one of the two great divisions of the *Nyâya* (q.v.) school of Hindu philosophy, and probably a later development of the Nyâya itself, properly so called, with which it agrees in its analytical method of treating the subjects of human research, but from which it differs in the arrangement of its topics, and more especially by its doctrine of atomic individualities or *vis'eshas*—whence its name is derived.

The topics or categories (*padârthas*) under which *Kan'âda*, the founder of this system, arranges his subject-matter, are the following six: (1) substance, (2) quality, (3) action, (4) generality, (5) atomic individuality, and (6) co-inherence; and later writers of his school add to these a seventh category, viz., non-existence. 1. Substance is the intimate cause of an aggregate effect; it is that in which qualities abide, and in which action takes place. It is ninefold, viz., earth, water, light, air, ether, time, space, soul, and *manas*, or the organ of affection. 2. Quality is united with substance; it comprises the

following 24: color, savor, odor, feel, number, dimension, severalty, conjunction, disjunction, priority, posteriority, gravity, fluidity, viscidity, sound, understanding, pleasure, pain, desire, aversion, volition or effort, merit, demerit, and self-restitution. 3. Action consists in motion, and abides in substance alone. It affects a single, that is, a finite substance, which is matter. Action is either motion upward or motion downward, or contraction or expansion, or motion onward. 4. Generality abides in substance, quality, and action. It is of two kinds, higher and lower—genus and species. 5. Atomic individuality resides in eternal substances, by which are meant the organ of affection, soul, time, space, ether, earth, water, light, and air; it is the ultimate difference, technically called *vis'esha;* such differences are endless; and two atoms of the same substance, though homogeneous with one another, differ merely in so far as they exclude one another. 6. Co-inherence, or perpetual intimate connection, resides in things which cannot exist independently from one another, such as the parts and the whole, quality and the thing qualified, action and agent, species and individual, atomic individuality and eternal substance. 7. Non-existence, the last category, added to the foregoing by the modern Vais'eshikas, is defined by them as being either non-existence, which is without beginning, but has an end—as that of a jar, which did not exist until its antecedent non-existence ceased when being formed out of the clay; or non-existence, which has a beginning, but no end—as that of a jar which is smashed by the blow of a mallet; or absolute non-existence, which, extending through all times, has neither beginning nor end—as when it is said that a jar is not on the ground; or mutual non-existence, which is the reciprocal negation of identity—as when it is remarked that a jar is not a piece of cloth. The nature of each of these substances, qualities, actions, etc., is then the subject of special investigation. Thus, *earth* is said to be that of which the distinguishing quality is odor; it is described as being of two kinds: eternal in its atomic character; and uneternal when in the shape of some product. Again, products are defined as either organized bodies of five sorts, or organs of perception, or unorganic masses, such as stones, etc. Among the qualities, color is defined as that quality which is apprehended only by the sense of sight; which resides in earth, water, and light; which is distinguishable in earth as white, yellow, green, red, black, tawny, and variegated; in water, as white, but not resplendent; in light, as white and resplendent, etc. *Self-restitution*—to give another instance of the definition of the qualities—is described as threefold: as impetus, the cause of activity in earth, water, light, air; and the organ of affection; as the mental process peculiar to the soul, which is the cause of memory; and as elasticity, in mats and similar substances, which causes an altered thing to reassume its former position.

Though this cursory statement must here suffice to give a general idea of the Vais'eshika system, it is worthy of especial notice that, according to it, understanding is the quality of *soul*, and the instruments of right notion are treated of under the head of "understanding (*buddhi*)." Kan'âda admits of only two such instruments, or *pramân'as*, viz., knowledge which arises from the contact of a sense with its object, and inference. Comparison, revelation, and the other instruments of right notion, mentioned in other systems, the commentators endeavor to show are included in these two. Fallacies and other modes of inconclusive reasoning are further dealt with in connection with "inference," though with less detail than in the Nyâya, where these topics are enlarged upon with particular predilection.—The reputed founder of the Vaiseshika is *Kan'âda*, which name the native authorities derive from *kan'a*, minute, and *âda*, eating, and sometimes, therefore, also change into *Kan'abhuj* or *Kan'abhaksha* (*bhuj* and *bhaksha* being synonyms of *âda*). Nothing, however, is known as to the history or date of this personage, as they are involved in the same obscurity which covers most of the renowned writers of ancient India. His work is divided into ten *adhya'yas*, or books, each of which is subdivided into two diurnal lessons; these, again, being subdivided into sections containing two or more *sûtras* (q.v.), on the same topic. Like the Nyâya-Sûtras, the work of Kan'âda has been commended upon by a triple set of commentaries, and popularized in several elementary treatises. The text with the commentary of *S'ankara Mis'ra*—who is not to be confounded with the celebrated Vedânta author—has been edited at Calcutta in 1861 by the Pan'd'it Jayanârâyana Tarka Panchânana, who added to it a gloss of his own; and some of the sûtras have been translated by the late Dr. Ballantyne (Mirzapore, 1851). Of later works on the same system, may be mentioned the *Bhâshâparich chheda*, edited with the commentary called *Siddhântamuktâvali*, and translated by the late Dr. Roer in the *Bibliotheca Indica* (Calcutta, 1850), and the popular *Tarkasangraha* in several editions; edited also and translated by Dr. Ballantyne (2d edit., Calcutta, 1848), who in his preface gives a catalogue of the commentaries which this work has elicited. The reader not acquainted with Sanskrit is, for further information on the subject, referred to these translations, and to the essays on the Vaiseshika system by H. T. Colebrook (*Miscellaneous Essays*, vol. i., Lond., 1837), and Prof. M. Müller, in the 6th and 7th vols. of the *Zeitschrift der deutschen morgenländischen Gesellschaft.*

VAISHN'AVAS is the name of one of the three great divisions of Hindu sects. See INDIA, section *Religion.* The word, derived from *Vishn'u* (q.v.), designates the worshipers of this deity, and comprises a great variety of sects; but this variety itself differs according to different periods of the mediæval history of India, old divisions becoming

extinct, and new ones taking their place. Thus, the account of the Vaishn'avas, as given in a celebrated work of *Anandagiri*, the *S'ankara-dig-vijaya*, or the victory of the great theologian S'ankara over his religious adversaries, would no longer apply in detail to the present condition of the Vaishn'avas; and even some of those varieties mentioned by the late prof. Wilson in his *Sketch of the Religious Sects of the Hindus*, written in 1832, would seem to have disappeared already in our days. The common link of all the sects comprised under the name of Vaishn'avas, is their belief in the supremacy of Vishn'u over the other gods of the Trimûrti (q.v.). Their difference consists in the character which they assign to this supremacy, and to the god Vishn'u himself in the religious and other practices founded on the nature of their belief, and in their sectarian marks. The following sects belonging to this category may especially be noticed here.

1. The *Râmânujas*, or *S'rî Vaishn'avas*, or *Srî-Sampradâyins*. They derive their origin from *Râmânuja*, a celebrated reformer, who was born at Perumbur, in the s. of India, about the middle of the 12th c., and is considered by his followers as an incarnation of *S'esha* (q.v.), the serpent of Vishn'u. He studied at Conjeveram, resided afterward at S'rîranga, and then traveled over different parts of India, where he was especially engaged in combating the professors of different creeds, particularly the S'aivas. On his return to S'rîranga, he was seized by the king Kerika'la Chola, but effected his escape, and found refuge with the Jain king of Mysore, Vitâla Deva, whom he converted to the Vaishn'ava faith. For 12 years he then remained at Mysore; but at the death of the Chola king, returned to S'rîranga, where he spent the remainder of his life in religious seclusion. The Râmânujas address their worship to Vishn'u and his consort, Lakshmî (q.v.), and their respective incarnations, either singly or conjointly. Hence their sect consists of corresponding subdivisions, according as Nârâyan'a or Lakshmî, or Lakshmî-Nârâyan'a, or Râma, or Sîtâ or Sîtâ-Râma, or any other incarnation of these deities, is the preferential object of the veneration of the votary. Their most striking peculiarity is the preparation and the scrupulous privacy of their meals; for should the meal during its preparation, or while they are eating it, attract even the looks of a stranger, the operation is instantly stopped, and the viands buried in the ground. The marks by which they distinguish themselves from other sects are two perpendicular white lines, drawn with a white earth, *gopîchandana*, from the root of the hair to the commencement of each eyebrow, and a transverse streak connecting them across the root of the nose; in the center is a perpendicular streak of red, made with red sanders, or a preparation of tumeric and lime; other marks, representing several of the attributes of Vishn'u, they have either painted or impressed on the breast and each upper arm; and, besides, they wear a necklace of the wood of the Tulasî (holy basil), and carry a rosary of the seeds of the same plant, or of the lotus. The sacred formula with which a member of this sect is initiated into it consists merely of the words *Om râmâya namah'*, "Om, salutation to Râma." Their principal religious tenet is the belief that Vishn u is the cause and creator of all the worlds; that he and the universe are one, though he is of a twofold form, the supreme spirit or cause, and the gross one, the effect or matter. In distinction from the Vedânta, with which their doctrine has otherwise many points of contact, they regard their supreme deity as endowed with qualities, all of which are of course excellent; and teach that the universe consists of *chit*, thinking or spirit, *achit*, unthinking or matter, and *îs'wara*, or god; the relation of which is that of enjoyer, the thing enjoyed, and the ruler of both. The deity, they assume, is or has been visibly present in five modifications, in the objects of worship, as images, etc.; in the incarnations (see under VISHN'U); in certain forms called Vyûhas, viz., Vâsudeva or Kr'ishn'a; Balarâma, Pradyumna, and Aniruddha; and in the subtle form which comprises six qualities—absence of passion, immortality, exemption from pain or care, absence of natural wants, love, and practice of truth—and the human soul; all of which have to be worshiped seriatim, as the votary ascends in the scale of perfection. The chief authoritative works in Sanskrit of this sect are the *Vedânta Sûtras*, with several commentaries, several works on the Vedânta (q.v.) philosophy, the *Pancharâtra* of Nârada; of Purân'as (q.v.), the *Vishn'u-*, *Nâradîya-*, *Garud'a-*, *Padma-*, *Varâha-*, and *Bhâgavata-Purân'a;* and besides, the works of *Venkat'a*, and several popular works in the dialects of the south. It is in the s. that the followers of Râmânuja, and their temples and establishments, are still numerous; in the n. of India, where they are better known as *S'rî Vaishn'avas*, they are not of frequent occurrence.

2. The *Rámánandas Rámávats*. They are by far the most numerous class of sectaries in Gangetic India: in the district of Agra, they alone constitute seven-tenths of the ascetic population. They belong chiefly to the poorer and inferior classes, with the exception of the Rajputs and military Brahmans. The founder of this sect was *Rámánanda*, who, by some, is considered to have been the immediate disciple of Râmânuja, by others, the fifth in descent from that teacher, when he would have lived about the end of the 13th c.; but other more reliable accounts place him toward the end of the 14th, or the beginning of the 15th century. According to common tradition, Râmânanda seceded from the Râmânujas to whom he originally belonged, because, having spent some time in traveling through various parts of India, and in consequence having been suspected by his fellow-disciples not to have conformed to the rule of the Râmânujas in taking his meals, he was condemned to feed in a place apart from the rest of them, but did not acquiesce in the affront thus offered him. His residence was at Ben-

ares, at the Pancha Gangâ Chât', where a *math*, or monastery, of his followers is said to have existed. The especial object of their worship is Vishn'u, in his incarnation as *Râmachandra*, and his consort *Sîtâ*, and, as amongst the Râmânujas, these deities either singly or jointly. Some members of this sect also pay adoration to other forms of Vishn'u; and the religious mendicants of the sect consider all form of adoration superfluous, being content with the incessant invocation of Krishn'a and Râma. Their practices are less precise than those of the Râmânujas; but the most important difference between them consists in the fact that Râmânanda abolished the distinction of caste among the religious orders, and taught that a *Vairâgin*, or one who quitted the ties of nature and society, shook off at the same time all personal distinction. The initiatory formula of Râmânanda is *S'rî Râma*, or "blessed Râma." Their sectarian marks are the same as those of the Râmânujas, except that the red perpendicular streak on the forehead is varied in shape and extent, and generally narrower than that of the Râmânujas. There are various subdivisions of this sect, believed to have been founded by several eminent disciples of Râmânanda. Their doctrines vary often from that of the latter, but they maintain an amicable intercourse with the Râmânujas and with each other. The twelve chief disciples of Râmânanda were *As'ánand, Kabîr, Raidás, Pipá, Sursurânand, Sukhânand, Bhavânand, Dhavana, Sena, Mahânand, Paramânand,* and *S'rî Anand;* and besides these *Nábhâji*, the author of the Bhaktamâlâ, *Sûr-Dás, Tulasî-Dás*, the translator in Hindi of the Râmâyan'a, and the author of many popular works which exercise a considerable influence on the Hindu population, and the poet *Jayaadeva*, the author of the Gîtagovinda. Many legends, of course, are related of these personages, especially in the Bhaktamâlâ, the favorite work of this sect.

3. The *Kabîr Panthis.* The founder of this sect, one of the most interesting and important in upper and central India, except, perhaps, in Bengal itself, was Kabîr, the most celebrated of the twelve disciples of Râmânanda before mentioned, who, therefore, probably lived about the end of the 14th century. The circumstances connected with his birth, life, and death are all related as miraculous; and so little is certain about his life that even the Mussulmans claim him as one of their persuasion. But his great conversancy with the Hindu *S'âstras*, and his limited knowledge of the Mohammedan authorities, render such a supposition highly improbable. According to the doctrine of this sect, there is but one God, the creator of the world; but, in opposition to the Vedânta (q.v.), they assert that he has a body formed of the five elements of matter, and a mind endowed with the three *gun'as*, or qualities: he is of ineffable purity and irresistible power, eternal, and free from the defects of human nature, but in other respects does not differ from man. The pure man is his living resemblance; and after death, becomes his equal and associate. God and man are therefore not only the same, but both in the same manner everything that exists. For 72 ages, God was alone; he then felt the desire to renew the world, which desire assumed the shape of a female form; and this form is Mâyâ (q.v.), or illusion, with whom he begot the triad, Brahman, Vishn'u, and S'iva. He then disappeared, and Mâyâ approached her offspring in order to frame the universe. Vishn'u hesitated to associate with her, and is therefore more respected by the Kabîr Panthis than the other two gods of the triad; but the latter were frightened by her, and the result of their submission was the birth of Saraswatî, Lakshmî, and Umâ, whom she wedded to the three deities to produce the world. To understand the falsehood of Mâyâ is, therefore, the chief aim of man; and so long only as he is ignorant of the source of life, he is doomed to transmigration (q.v.), which, according to the belief of this sect, is also extended to the planetary bodies—a falling star or meteor being a proof, for instance, that it undergoes a fresh change. The moral code of the Kabîr Panthis is, in many respects, creditable to them. Life, they teach, being the gift of God, must not be violated by his creatures. Humanity and truth are two of their cardinal virtues; retirement from the world is deemed desirable; and implicit devotion, in word, act, and thought, to the guru, or spiritual teacher, a supreme duty. But, as regards the latter point, it is characteristic that the pupil is enjoined first to scrutinize the teacher's doctrine and acts, and to be satisfied that he is the sage he pretends to be, before he resigns himself to his control. It is no part of their faith to worship any deity, or to observe any ceremonies and rites of the Hindus; but they are recommended outwardly to conform to all the usages of tribe and caste, and some even pretend to worship the usual divinities, though this is not considered justifiable. They have no peculiar mode of dress, and though some wear the sectarian marks of the Vaishn'avas, and the necklace and rosary, all these outward signs are considered of no importance. Though, therefore, properly speaking, they can scarcely be included amongst the Vaishn'ava sects, yet their paying more respect to Vishn'u than to any other god of the Trimûrti (q.v.), and the fact of Kabîr having been a disciple of Râmânanda, also the friendly intercourse which they maintain with most of the Vaishn'ava sects, cause them always to be looked upon as belonging to them. The doctrines of Kabîr are taught in a great variety of works in different dialects of Hindi, all of which are the acknowledged compositions of his disciples and successors. The principal are the *Sákhîs*, 5,000 in number, consisting of one stanza each; the *Bîjak*, in 654 sections; and the *Sukh Nidhân.* The sect itself is split into a number of subdivisions, and twelve branches of it are traced to the following personages: *S'rutgopál Dás*, the author of the Sukh Nidhân—his successors preside over the Chaura at Benares; *Bhâgo Dás*, the author of the Bîjak;

Nárâyan Dás and *Churâman' Dâs*, the two sons of a merchant at Jabbalpur; *Jaggo Dâs*, of Kuttack; *Jîvan Dâs; Kamâl*, of Bombay; *Tâk Sâlî*, of Baroda; *Jnânî*, of Majjhni, near Sahâs'râm; *Sâheb Dâs*, of Cuttack; *Nityânand*, and *Kamál Nâd*, in the Dekhan. The principal establishment of the sect is the Kabîr Chaura at Benares.

4. The *Vallabhácháryas*, or *Rudra Sampradáyins*. The original teacher of this sect is said to have been *Vishn'u Swámin;* but it is a later successor of his, *Vallabha Swámin*, or *Vallabha Acha'rya*, who, from the influence which his teaching and writing exercised on the propagation of his doctrines, must be considered the real founder of this sect. He was born in 1479, in a forest called Champâran'ya, where his parents deserted him on a pilgrimage they had undertaken to Benares. The gods, of course, took care of the infant, and his parents, who recovered him afterward, took him to Gokula, a village on the left bank of the Jumna, a short distance from Mathura, where he received his first education. In his twelfth year he left this place in order to propagate throughout India his tenets, which at that time, it must be understood, he had already framed. On arriving at a certain town in the s. of India, he became acquainted with a person of influence, *Damoradás*, whom he converted to his doctrine. Both of them then proceeded together to the city of Vijayanagar, where the maternal parents of Vallabha resided. He was now introduced to the court of the king of Vijayanagara, Krishn'adeva, and succeeded so well in his disputation with the S'aivas and Smârta Brâhmans that not only the king bestowed on him rich presents, but the Vaishn'avas elected him as their chief, with the title of Âchârya, or spiritual teacher. He then traveled to Ujjayin, Allahabad, and Benares, and from there for 9 years through different parts of India, until, on his return to Brindâvan, as a reward for his exertions and faith, he was honored by a visit from the god *Kr'ishn'a* in person, who enjoined him to introduce his worship, and to found the religion now so widely diffused throughout western India under the sectarian name of *Rudra Sampradáya*. Vallabha ultimately settled at Benares, and there composed 17 works in Sanskrit, the most important of which are a commentary on the Vedânta (q.v.) and Mimânsâ (q.v.) Sûtras, and one on the Bhâgavata Purân'a; works, however, only intended for the learned, and now very rare. He died on a hill in the vicinity of Benares, in his 53d year, after having made 84 devoted disciples. He was succeeded by his second son, *Vithalnâthji*, who was born in 1516, in the village of Parn'ât, and is known amongst the sect by the designation of S'rî Gosâin Jî, his father Vallabha's sectarian name being S'rî Achârya Jî. Vithalnâthji died in 1583, and left besides four daughters, seven sons, who were all teachers, and formed as many communities, viz.: *Girdharji* (born 1540), *Govinda Ráy* (born 1542), *Bâlkr'ishn'aji* (born 1549), *Gokulnâthji* (born 1551), *Ragunâthji* (born 1554), *Jadunâthji* (born 1556), and *Ghanashyamji* (born 1561). It was, however, *Gokulnáthji* who became the most celebrated of the descendants of Vithalnâthji, for to him especially is due the vitality of this sect, and even to the present day the followers of his descendants consider their own Gosâins the only legitimate teachers of their faith, while even the adherents of the other sons of Vithalnâthji pay them the greatest respect. It is about the period when the sons of Vithalnâthji dispersed that they first acquired the title of *Mahârâj*, or "great king," by which the chiefs of this sect are now best known, though besides this proud designation they have other distinctive titles, such as *Vallabha Kula*, *Agni Kula*, *Guru*, etc. The heads of the Gokulnâthji division of this sect are usually called *Gokul Gosâins*, or *Gokulastha Gosâins*. The members of this sect are widely diffused throughout Bombay, Cutch, Kattywar, and central India, and especially the province of Malwa. Their establishments and temples are numerous throughout India, especially at Mathura, Brindâvan, and Benares. The most celebrated of all is at S'rî Nâth Dwâr, in Ajmeer, and the members themselves belong to the better and wealthier classes of the Hindu community. At present there are about 60 or 70 "Mahârajas" of this sect dispersed over India, 8 or 10 of whom reside at Bombay alone, and 15 or 16 at Gokul. But so much degenerated are they as a body, that only 2 or 3 of them have any knowledge of Sanskrit; the rest, as a distinguished writer on this sect, Mr. Karsandâs Mulji, asserts, being grossly ignorant; for, as Wilson remarks, it is a curious feature in the notions of this sect that the veneration in which he Gosâins are held is paid solely to their descent, and unconnected with any idea of their sanctity and learning; and that, though they are not unfrequently destitute of all pretensions to individual respectability, they nevertheless enjoy the unlimited homage of their followers.

The chief authority of the sect is the *Bhâgavata Purân'a* (q.v.), and after it the works of Vallabha and various books, 74 in number, 39 of which are translations from Sanskrit, and the rest original compositions in the Brijbâshâ dialect. The object of their adoration is Vishn'u (q.v.) in his incarnation as Kr'ishn'a, whose residence is Goloka, far above the three worlds. There he originally lived alone, but in meditating on the works of creation, created a female form, which became the primary agent in creation: This was Mâyâ. He then produced crude matter, the five elements, and all the divine beings; the gods of the Trimûrti, their female consorts, and 300,000,000 of Gopîs, or cowherdesses, who are the especial attendants on Kr'ishn'a. The principles of the sect, as laid down by Vallabha, are the following ten: 1. To secure the firm supprt of Vallabhâchârya; 2. To exercise chiefly the worship of Kr'ishn'a; 3. To forsake the sense of Vaidik opinion and be a suppliant to Kr'ishn'a; 4. To sing praises with feelings of humility; 5. To believe that Vallabha is a Gopî, or mistress of Kr'ishn'a; 6. To swell the heart with the

name of Kr'ishn'a; 7. To forsake his commands not for a moment; 8. To put faith in his words and doings; 9 To adopt the society of the good, knowing them divine; and, 10. To see not the faults, but speak the truth. Out of this code, however, grew up the doctrine that the Guru or Mahârâj is the impersonation of Kr'ishn'a himself, that God and the Guru are necessarily to be worshiped, and that the sectary is bound to bestow on him "his body, organs of sense, life, heart, and other faculties, and wife, house, family, property, with his own self." The gross abuse which was made of this tenet became apparent in a very remarkable trial, the so-called Mahârâj libel case, which took place in 1861 in the supreme court of Bombay, and revealed the licentiousness of one of the then Mahârâjas of the sect of Bombay; the defendant sued for libel by this Mahârâj being a highly respected and distinguished member of the sect, Mr. Karsandâs Mulji, who had had the courage of calling, in a native newspaper, on the Mahârâjas to reform and to return to the ancient Hindu faith, and whose public conduct on that occasion elicited the highest praise of the court, and, it is to be hoped, initiated a better era of this sect. The temples of the sect have images of Kr'ishn'a, and Râdhâ, his principal wife; the former representing a chubby boy, of a dark hue, who is richly decorated, and eight times a day receives the homage of his worshipers. The ceremonial which on those occasions take place are the *mangala*, or morning levee, about half an hour after sunrise, when the image is washed and dressed, and presented with refreshments; the *s'ringâra*, when the image having been anointed and perfumed, holds his public court—this takes place about an hour and a half after the preceding; the *gwâla*, 48 minutes after the last, the image being now visited preparatory to its going out; the *râjabhogâ* held at mid-day, when Kr'ishn'a is supposed to have come home from the pastures and sat down to dine—all sorts of delicacies are then placed before the image, and distributed to the votaries present; the *utthâapana*, three hours before sunset, when the god is summoned to get up from his siesta; the *bhoga*, or afternoon meal, about half an hour later; the *sandhyâ*, about sunset, or the evening toilet of the image; and the *s'ayanâ*, or retiring to repose, about 7 in the evening; the image then being put upon a bed and refreshments being placed near it, when the votaries retire, and the temple is shut till the ensuing morning. Besides these ceremonies, there are other annual festivals observed by this sect throughout India; of these the *Rath Yâtra*, or procession of the god in a chair, is the most celebrated in Bengal and Orissa; the most popular at Benares is the *Janmâshtamî*, or the nativity of Kr'ishn'a; and the *Râs Yâtra*, or annual commemoration of the dance of Kr'ishn'a with 16 Gopîs—a very popular festival, at which all kind of rejoicings take place. The mark on the forehead of the Vallabhâchâryas consists of two perpendicular lines meeting in a semi-circle at the root of the nose, and having a round spot of red between them. On the breasts and arms they have the same marks as the Râmânujas, made with a black earth called *S'yâmabandî*, or any black metallic substance; their necklace and rosary are made of the stalk of the Tulasî (holy basil) plant. For a fuller account of this sect, its authorities, festivals, and worship, and the practices of the Mahârâjas, see the interesting *History of the Sect of Mahárájas or Vallábhácháryas in Western India* (by Karsandâs Mulji—London, 1865), which also contains the history of the "Mahârâj Libel Case" above referred to.

5. The *Mâdhwâcháryas* or *Brahma Sampradâyins*. This sect occurs especially in the peninsula, and was founded by a Braham, *Mâdhwâchârya*, who is looked upon by his followers as an incarnation of Vâyu, the god of wind, after having been incarnate in preceding ages as Hânuman (q.v.) and Bhîma. He was born in the year 1199, and educated in a convent at Anantes'war. In his ninth year he was initiated into the order of anchorites by Achyuta Pracha, a descendant of Sanaka, a son of Brahman. At that early age he composed a commentary on the Gîtâ; then traveled to the Himâlaya, and, when returned, erected at Udipi the image of Kr'ishn'a, which had been originally made by Arjuna, and miraculously recovered by him. In addition to the principal temple at Udipi, he established eight other temples in Tuluva, below the Ghâts; composed, it is related, 37 works, and, on a controversial tour, triumphed over various divines. In his 79th year he went to Badarikâs'rama, where, the legend says, he continues to reside with Vyâsa, the compiler of the Vedas and Purân'as. It seems that he was originally a priest of the S'aiva faith, and one of his names, *Ananda T'îrtha*, even indicates that he belonged to the class of Das'namî Gosâins, who were instituted by *S'ankarâchârya* (q.v.). He encouraged, therefore, an attempt to form a kind of compromise between the S'aivas and Vaishn'avas; and in the temples of his sect, images of S'iva are allowed to partake of the worship offered to those of Vishn'u. Votaries of the Mâdhwa Gurus and of S'ankarâchârya Gosâins offered also the reverential obeisance to their teachers mutually, and the latter visit the temple of the former to perform their adoration at the shrine of Kr'ishn'a. The essential dogma of this sect is the identification of Vishn'u with the supreme soul, as the pre-existent cause of the universe; and this primeval Vishn'u they affirm to be endowed with real attributes, and, although indefinable, to be most excellent and independent. But besides this independent, there is also a dependent, principle; for besides the supreme soul, *Paramâtman*, there is a living soul, *Jîvâtman*, which is dependent on the supreme; and though indissolubly connected with, yet not the same with him. In consequence, they deny the absorption of the human soul into the universal spirit, and the loss of independent existence after death. In this respect they differ, therefore, on a vital point of doctrine, from the members of other Vaishn'ava and

S'aiva sects. The manner in which they conceive the universe to have issued from the Supreme Being is to a great extent analogous to that of the other Vaishn'avas; and they also receive the legends of the Vaishn'ava Purân'as relating to the birth of Brahman, from the lotus, which grew out of the navel of Vishn'u, etc. The modes of worshiping Vishn'u they declare to be three: marking the body with his symbols, especially by means of a hot iron; giving his names to children and objects of interest; and the practice of virtue in word, act, and thought. That in word consists in telling the truth, giving good counsel, mild speaking, and study; that in act comprises liberality, kindness, and protection; and clemency, freedom from envy, and faith are the practice of virtue in thought. Final liberation, or freedom from future birth, they consider as the reward for having secured the favor of Vishn'u by sedulously worshiping him; and those who have attained it enjoy felicity in Vishn'u's heaven, under one or all of the four conditions: of being similar to him in form, of remaining in his visible presence or in his proximity, and of sharing equal power with him.

Their worship is not materially different from that of the other Vaishn'avas, except in one peculiarity, which proves that they have a friendly leaning toward the S'aiva sect; for the images of S'iva, Durgâ, and Gan'es'a are placed by them in the same shrine as Vishn'u. The Gurus, or superiors, of this sect are Brahmans and asceties, or profess cœnobitic observances; the disciples live in their *maths*, or monasteries, and profess also perpetual celibacy. The lay votaries of these teachers are members of every class of society except the lowest. The Gurus adopt the external appearance of ascetics, laying aside the Brahmanical cord, carrying a staff and water-pot, going bareheaded, and wearing a single wrapper of an orange color. The marks common to them and the lay votaries are the symbols of Vishn'u upon shoulders and breast, and the frontal mark, consisting of two perpendicular lines made with the white clay *Gopîchandana*, and joined at the root of the nose, like that of the Râmânujas; but instead of a red line down the center, they make a straight black line with the charcoal from incense offered to Nârâyan'a, terminating in a round mark made with turmeric. The scriptural authorities of this sect are, besides the writings of its founder, the four *Vedas*, the *Mahâbhârata*, the *Panchârâtra*, and the original *Râmâyan'a*.

6. The *Vaishn'avas of Bengal*, the far greater number of worshipers of Vishn'u, in Bengal, form one-fifth, or according to another estimate, nearly one-third of the population of this province. Their founder, *Chaitanya*, was the son of a Brahman settled at Nadîya, but originally from Silhet. He was born in 1485, and his birth was accompanied by the usual potentous indications, described in Hindu legends, of a superhuman event. He was, in fact, an incarnation of Kr'ishn'a, who appeared for the purpose of instructing mankind in the true mode of worshiping him in this age. Up to his 24th year Chaitanya seems to have lived without any great pretensions to sanctity; he married, it is said, a daughter of Vallabhâchârya, and supported his mother after the death of his father, which occured in his childhood. At twenty-four, however, he shook off the obligations of society, and became an ascetic, traveled between Mathurâ and Jagannâth, and taught his doctrine. At the end of his peregrinations, he nominated his two principal disciples, *Adwaitânand* and *Nityânand*, to preside over the Vaishn'avas of Bengal, and *Rûpa* and *Sanâtana* over those of Mathurâ. Chaitanya himself then settled at Cuttack, where he remained twelve years, engaged in teaching and controversy, and in intent meditation on Kr'ishn'a. There he had frequent visions of Kr'ishn'a, Râdhâ, and the Gopîs, and in one of these fits of ecstasy, was nearly drowned in the Jumna. Ultimately, he disappeared—how, is not known—about 1527. Of his two chief disciples, *Adwaitânand* resided at S'ântipur, and seems to have been a man of some property and respectability. *Nityânand* was a resident of Nadîya, and a householder, and his descendants are still in existence. Besides these three Prabhus, or chiefs, the Vaishn'avas of Bengal acknowledge six Gosâins as their original teachers, viz., *Rûpa, Sanâtan, Jîva, Raghunâth Bhat't', Raghunâth Dâs*, and *Gopâl Dâs;* and next to them they hold in veneration *S'rînivâs, Gadâdhar Pan''dit, S'rî Svarûpa, Râmânand*, and others including *Hâridâs*, who especially obtained almost equal honor with his master Chaitanya. In addition to these chiefs, the sect claims eight eminent poets, among whom *Krishna Dâs* is the most celebrated. According to the doctrine of the sect, *Kr'ishn'a* is the supreme spirit, who, for various purposes, assumed specific shapes, in which he became incarnate (see VISHN'U); and so far there is not much real difference between the tenets of this and other Vaishn'ava sects. But an important innovation, introduced by its founder, is the doctrine of *Bhakti*, or faith, which, he teaches, is infinitely more efficacious than abstraction, than knowledge of the divine nature—as enjoined by the philosophical systems—than the subjugation of the passions, than the practice of the Yoga, than charity, virtue, or anything deemed most meritorious. A consequence resulting from this doctrine is, that all castes become by such faith equally pure, and therefore that all castes are admissible into the sect; that all are at liberty to sink their social differences in the condition of ascetics, in which character they may live with each other without regard to former distinctions, and that all members of the sect are equally entitled to the food which has been previously presented to the deity. The *Bhakti*, or faith, comprehends five stages: quietism, as that of sages; servitude, which every votary takes upon himself; friendship for the deity, such as is felt by Bhîma and others honored with his aquaintance; tender affection for the deity, of the same nature as love of parents for their

children; and the highest degree of affection, such passionate attachment as the Gopîs felt for their beloved Kr'ishn'a.

The manner of expressing these feelings in acts of divine worship is about the same as that represented by the ceremonial of the Vallabhâchâryas; but the secular worshipers are generally content with paying their homage twice a day to the idol of Kr'ishn'a. Their chief ritual is a very simple one; it consists of constantly repeating the name of Kr'ishn'a—a practice of which one of their chiefs, Haridâs, set them a remarkable example, as during many years, when he resided in a thicket, he repeated the name of Kr'ishn'a 300,000 times daily. Their other duties are sixty-four, including many moral and many absurd observances, as suppressing anger, avarice, and lust, and singing and dancing in honor of Kr'ishn'a, and fasting every eleventh day. The most important of all their obligations, however, is their servile veneration of the spiritual teacher, whom they are bound to look upon as the deity himself, and even as possessed of more authority; for they are taught that "the prayer is manifest in the Guru, and the Guru is Vishn'u himself;" again: "First, the Guru is to be worshiped, then I (Vishn'u) am to be worshiped;" and, "when Vishn'u is in anger the Guru is our protector; but when the Guru is in anger, we have none." In this respect, the doctrine of the Vaishn'avas of Bengal is similar to that of the Vallabhâchâryos, and their practice also agrees in so far as the Vaishn'avas look upon the dignity of their Gurus as hereditary, and not depending on personal capacity or sanctity; but, as in the case of the Vallabhâchâryas, this practice does not appear to have been enjoined by their original teachers. Liberation from terrestrial existence, most votaries of this sect do not conceive in the spirit of the Vedânta, which teaches that final deliverance is the absorption of the human soul into the divine essence; but, in their opinion, it is twofold, either perpetual residence of the soul in Swarga, or paradise, with possession of the divine attributes of power, etc.; or elevation to *Vaikun't'ha*, the heaven of Vishn'u, where they enjoy felicity under one or all of the four conditions, under which also the Madhwâchâryas conceive such felicity to exist. Chaitanya and his two chief disciples did not leave, as it seems, written compositions; the rest of his pupils, however, wrote numerous works in Sanskrit and Bengali. The Vaishna'vas of this sect are distinguished by two white perpendicular streaks of sandal, or *Gopîchandana*, down the forehead, uniting at the root of the nose, and continuing to near the tip; by the names of *Râdhâ-Kr'ishn'a* stamped on the temples, breast, and arms; by a close necklace of Tulasî stalk of three strings, and a rosary of 108 or sometimes 1000 beads made of the stem of the Tulasî. The sectaries consist of every caste and order, and are governed by the descendants of their Gosâins: some live in a state of celibacy; the teachers, however, are married men.

There are several divisions of this sect, arising from the various forms under which Vishn'u is worshiped; but besides them, there are three which may be looked upon as seceders from the original sect—viz., the *Spasht'a Dâyakas*, the *Kartâ Bhâjas* and the *Sâhujas*.

The *Spasht'a Dâyakas* deny the divine character and authority of the Guru, and allow the association of male and female cenobites in one conventional abode, where their relation is that of brothers and sisters, and their common interest the worship of Kr'ishn'a and Chaitanya. The women act also as the spiritual teachers of the females of respectable families, and the consequence is the growing diffusion of the doctrines of this sect in Calcutta, where it is especially established. The *Kartâ Bhâjas* are of very recent origin, and, as they acknowledge the absolute divinity of the Guru, there would not be much difference between them and the original body of the Vaishnavas of Bengal, had they not broken through the old line of hereditary teachers, and invested a new family with spiritual power—viz., that of their founder, *Râma-S'aran-Pâl*, who at the beginning of this century, was successful in his attempt to create this schism. Of the *Sâhujas*, very little is known, their professions and practices being kept secret. These are suspected not to be of a very moral character. The chief temples of the Vaishn'avas of Bengal are at Dwarakâ, Brindâvan, Jagannâth, Nedîya, Ambikâ, and Agradwîpa.

Besides these Vaishna'va sects, there are others of less importance, which it must here suffice merely to ennumerate by name—viz., the sect of the *Khâkins*, founded by *Kîl*, the disciple of Krishn'adâs, and established chiefly at Hanumángád'hí, in Oude; the *Mâlûk Dâsas*, founded by *Mâlûk Dâs* about 1600, or at the end of the emperor Akbar's reign—their principal establishment is at Kara Manikpur; the *Dâdû Panthis*, founded by *Dâdû*, a pupil of one of the Kabir teachers, about the same time, and established especially in Marwar and Ajmeer; the *Rai Dâsas*, founded by *Rai Dâs*, a disciple of Râmânanda, a sect, it is said, confined to the very lowest of the mixed Hindu castes, or the workers in hides and leather; the *Senâ Panthis*, who derive their origin from *Senâ*, the barber, the third of Râmânanda's disciples; the *Mîrâ Bâîs*, a subdivision of the Vallabhâchâryas, established by *Mîrâ Bâî*, the daughter of a petty Râjâ of Mertâ, and the wife of the Rân'a of Udayapur; the *Sanakâdi Sampradâyns* or *Nimâvats*, throughout upper India, founded by an ascetic Nimbâditya; the *Râdhâ Vallabhis*, who consider Harivam's' as their founder, a personage who lived about 300 years ago, and established a monastery at Brindâvan; the *Sakhî Bhâvas*, probably owing their origin to the last-mentioned sect; the *Charan' Dâsas*, whose chief seat is at Delhi, founded by *Charan' Dâs*, a merchant of the Dhûsar tribe, who resided at Delhi, in the reign of the second Alemgîr; the *Haris'chandis;* the *Sadhnâ Panthis*, founded by *Sadhnâ*, a butcher; and

the *Mádhavis*, founded by *Mâdho*.—For a fuller detail, see H. H. Wilson's *Sketch of the Religious Sects of Hindus*, edited by Dr. Rost in Wilson's works, vol. i. (Lond.1862).

VALAIS (Ger. *Wallis*), a frontier canton of Switzerland, bounded on the n. by the cantons of Vaud and Bern, and on the s. by Italy. Area, 2,020 sq.m.; pop.'88, 101,985. It forms one long and deep valley, included between two of the loftiest mountain chains of Europe—the Pennine and the Bernese Alps—and is drained by the Upper Rhone, which, rising at its north-eastern extremity, in the glacier of the Gallenstock, falls at the western boundary of the canton into the lake of Geneva. No European territory is more completely isolated by mountains; and it is rendered still more inaccessible by transverse chains, between which are inclosed narrow valleys. The greater part of the surface consists of barren mountain slopes; in their higher elevations, covered with the greatest of the Swiss glaciers. The forests and pasture-lands supply the inhabitants with their chief occupations. But grain-cultivation is not absent; the chief agricultural tract being the level ground, from a quarter of a m. to 3 m. wide, which lies along the main channel of the river. Here corn enough is grown to supply the wants of the inhabitants. The heat at the bottom of the valley is intense in summer, and Indian corn and the vine are grown with great success. The Valais opens into the lake of Geneva, and is connected by great high-roads, and now by railway, with the other parts of French Switzerland and Savoy. The Grimsel and Gemmi passes connect the eastern part of the valley with German Switzerland; and the Great St. Bernard and Simplon (q.v.) passes connect it with Italy. Formerly the cattle, the chief export of Valais, were driven over the Simplon into Italy; but now the railway, which ascends the valley to beyond Sion, on the Simplon road, threatens to divert this trade to western Switzerland and France. The inhabitants of the upper Valais—one-third of the population—speak German; those of the lower Valais, the Vaudois dialect of French. The line which separates the two languages lies along the ridges running n. from the Matterhorn to a point a little to the e. of Leuk. All the inhabitants are Roman Catholic. The Valais is subdivided into dixaines, each of which has its council, and may be said to form a republic. Each of the dixaines sends four members to a larger council or diet meeting at Sion. The upper part of the Valais, throughout the middle ages, acknowledged a very slight feudal dependence on the German empire; the lower part belonged to Savoy. At the period of the struggle of the Swiss with the duke of Burgundy, the upper Valais took possession of the lower Valais, and reduced it to the position of a vassal state; and in this condition it remained until 1798, the period of French conquest, when the distinction was set aside. As stated in the article SWITZERLAND, under the recent constitution, the suffrage was extended to the whole population of Valais, with results little expected by the liberal party in the Swiss diet. Sion (q.v.) and Martigny (q.v.) are the chief towns.

VALCKENAER, LUDVIG KASPAR, an eminent Dutch philologist, b. at Leeuwarden in 1715, studied at Franeker, and in 1741 became professor of Greek there. Subsequently, he was called to Leyden, where he died, March 14, 1785. Valckenaer was an admirable lecturer and commentator on the classics. To a thorough knowledge of their literature and antiquities he added a fine critical discernment and thoughtfulness. Among his more notable performances are his recasting of Ursinus's *Virgilius cum Scriptoribus Græcis Collatus* (Leeuwarden, 1747), his editions of the Greek grammarian Ammonius (Leyd. 1739; Leip. 1822), of the *Phœnissæ* (Franek. 1755; Leip. 1824), and the *Hippolytus* (Leyd. 1768; Leip. 1823), his *Diatribe in Euripidis Perditorum Dramatum Reliquias* (Leyd. 1767; Leip. 1824); his edition of the so-called *Epistles of Phalaris* (Gröning. 1777), and of the *Idylls* of Theocritus (Leyd. 1779–81; new ed., Leip. 1810). He also furnished a rich store of critical observations to Wesseling's Herodotus. Among his posthumous works are his *Callimachi Elegiarum Fragmenta* (Leyd. 1799), his *De Aristobulo Judæo* (Leyd. 1806), and his *Opuscula Philogica, Critica, Oratoria* (2 vols., Leip. 1808).

VALDAI HILLS. See NOVGOROD.

VALDEPE'NAS, a t. of New Castile, in the modern province of Ciudad Real, and 30 m. e.s.e. of the city of that name. It is a straggling mud-built town. Pop. abt. 14,000.

VALDÉS, ARMANDO PALACIO, Spanish novelist of the "Naturalistic" school, was born at Entralgo, in the province of Asturias, October 4th, 1853. His first novel, *El Señorito Octavio*, appeared in 1881. This was followed by *Marta y Maria* (1883), *José* (1885), an "idyll of truth," and *La Hermana de San Sulpicio* (1889). The last mentioned is considered the author's masterpiece, and is widely popular both at home and abroad. Between 1890 and 1895 Valdés has published *Maximina*, *La Espuma*, *La Fe*, *El Maestrante* and *El Origen de Pensamiento*. Nearly all of his works have been translated into English.

VALDÉS, JUAN DE, 1500–41; b. Spain; went to Germany, and was converted to the principles of the reformation, though he seems to have been no partisan, but to have sought the unity of the faith; resided at Naples, and became secretary to the king; united there with some friends in the study of the Bible, and wrote some commentaries and religious books. After his death his friends were accused by the inquisition of forming a new sect, called Valdesians, some of whom were put to death, others fled to foreign countries. Some of his works, published by an English Quaker, were: *Dos Dialogos; Alfabeto Cristiano; Dialogo de la Lengua; La Epistola de San Pablo á los Romanos i la 1 á los Corintios, ambas traduzidas i comentadas.*

VALDI'VIA, a fertile, generally level province in s. Chil, covered largely by timber, and drained by the Canten, Totten, Valdivia, and Rio Bueno rivers; 8315 sq.m.; pop. '94, (est.) 65, 186; bounded n. by province of Aranco, e. by Andes, s. by Llanquihue, w. by the Pacific, on which it has fine harbors. Valdivia formerly yielded gold largely, but the tyranny of the Spaniards in imposing slavery on the natives led to revolt and the ruin of the mines. The principal occupation is cattle raising. In the Andes region are several volcanoes; the highest, Villarica, 16,000 ft. high. The climate is moist but healthful. Capital, Valdivia.

VALDI'VIA, Pedro de, about 1498–1555; b. Spain; went with Pizarro to Peru; participated in the conquest of Venezuela, 1535; aided Pizarro in subduing the rebellion under Almagro; conquered Chili, 1540; founded Santiago, 1541, and Coquimbo, 1544; upon the murder of Francisco Pizarro, was recalled to Peru; appointed capt.-gen. of Chile, and of whatever countries s. of Peru he might conquer; founded the cities of Concepcion, Villa Imperial, Villa Rica, in 1551; conquered the Araucanians, who afterward took him prisoner and put him to death.

VÁLEI, a name given to the plantain in southern India. See Plantain.

VALENCE, a t. of France, capital of the dep. of Drôme, in a charming situation on the flank of a hill that borders the left bank of the Rhône, 65 m. s. of Lyons by railway. The walls with which it is surrounded give it a gloomy appearance. Silk-weaving and silk-throwing are carried on, manufactures of printed and other cottons, glassware, leather, and gloves, and commerce in silk, fruits, wines, liquors, and spirits. Pop. '91, 22,947.

VALEN'CIA, a small island on the s.w. coast of Ireland, forms part of the county Kerry, is separated from the mainland by a narrow arm of Valencia bay, and lies 38 m. w.s.w. from Killarney. It is 5½ m. long and 2 m. broad; the soil is in many places good; half the entire area is under cultivation; and there are about 2500 inhabitants. On the w. side, which is mainly high rocky moorland, there are valuable slate and flag quarries. On the n. side of the island is Valencia bay, an inlet of Dingle bay; and Valencia harbor, the most western in Ireland, is part of the bay of the same name. Here is the telegraphic station for three Atlantic cables, now in operation, which were laid in 1866 and 1880. Another Atlantic cable starts from Balinskellig bay, a little to the s. of Valencia. See Telegraph and Atlantic Telegraph.

VALENCIA, a former kingdom of Spain, now subdivided into three modern provinces of Valencia, Alicante, and Castellon de la Plana (see Spain), comprises a tract of country in the e. of Spain, washed by the Mediterranean, and bounded on the n. by Catalonia, and on the s. and s.w. by Murcia.

In the middle districts of the kingdom are small plains, abounding in lagoons where they border on the Mediterranean, but furnished with few harbors; both in the n. and s. are mountain ridges, offsets from the eastern edge of the great central plateau of Spain. Valencia is remarkable for its fine climate, and for its fertility in the well-watered districts. The fruitful localities called the *huertas* (gardens) yield three, and sometimes four harvests in the year. Neither wheat nor barley is largely grown, but the rice-crops are so abundant, that not only is the whole of Spain supplied with this article from Valencia, but a considerable quantity is also exported. The country is rich in iron, lead, copper, cinnabar, cobalt, and coals. The lagoons on the coast, especially that of Albufera, are rich in sea-fowls and fish. The inhabitants, in whom is observable a strong mixture of Moorish blood, are remarkably industrious, and Valencia is known to be the most active manufacturing province of Spain after Cataluña.

VALENCIA, a co. in New Mexico, divided nearly into two portions by the southern projection of Bernalillo co.; area, 8900 sq. m.; pop. '90, 13,876. Co. seat, Los Lunas.

VALENCIA, an ancient city and seaport of Spain, formerly capital of the kingdom, and now of the province of the same name, stands on the shores of the Mediterranean, 294 m. e.s.e. of Madrid by railroad. The Huerta—40 English sq. m. in extent—which surrounds the city, resembles an immense orchard, and is ingeniously watered by an intricate network of pipes and rivulets, laid down by the Moors eight centuries ago, and efficiently answering its purpose down to the present day. In this garden, the carob, citron, orange, palm, and mulberry grow in wild luxuriance. Nature, stimulated by constant moisture and a burning sun, exhibits a wonderful strength and fecundity. Valencia is surrounded by the ruined gates of old walls, erected by Pedro IV. in 1356; the interior of the city is striking and pleasing; most of the streets are macadamized; and while, in the old quarters, the houses are closely packed and gloomy-looking, well suited to keep out the enemy, *heat*—those recently erected are high, gayly colored in blue, rose, cream-color, etc.; decorated with elegant iron-gilt balconies, and furnished with courts freshened with flowers and cooled by fountains. Valencia is the see of an archbishop, and its cathedral, La Seo—the see—which was commenced in 1262, is classical in the interior, and Gothic in the exterior, is 350 ft. long, and at the transepts, 216 ft. wide. From the top of a tower which surmounts one of the portals, the view is said to be one of the most striking in Spain. In the cathedral and its chapels there are a number of magnificent pictures, including some by Ribalta and Joanes. The church of the Colegio de Corpus is quite a museum of pictures by Ribalta, who, according to Ford, has

painted heads equal to any produced by the old Venetians. There are also numerous and interesting picture-galleries, in the chief of which only the productions of the great Valencian school are to be seen. The custom-house, dating from 1758, is now the cigar factory. The university is well attended. Valencia has long been famous for its artistically carved fans, the production of which gives employment to large numbers of workmen. The industry declined somewhat after the introduction of Japanese fans into Europe, but in 1896 there were signs of revival which promised to regain for it its former importance. Other industries are the spinning and weaving of silk, the manufacture of hemp cloth, hats, glass, linen, leather, and Valencia tiles. Its port has been improved; it is now connected with Madrid by railway, and being to its own metropolis what Brighton is to London, it is much visited in summer by the *Madrilenos*, who contribute greatly to its prosperity. There is considerable commerce with Britain. Pop. '87, 170,763.

Valencia, or *Valentia de Cid*, is a very ancient city. It was destroyed by Pompey, and rebuilt by Sertorius, after which it became a *colonia*. It was taken by the Goths in 413 A.D., and by the Moors in 712. The *Cid* took it in 1094–95, and ruled despotically here till 1099. The union of Ferdinand and Isabella brought it under the Castilian crown. Suchet captured the city in 1812.

VALENCIA, a t. of South America, Venezuela, capital of the state of Carabobo, 90 m. s.w. of Caracas, about 2 m. w. of a lake of the same name, and about 24 m. from Puerto Cabello on the coast, with which and with Caracas it carries on an active trade. There are celebrated hot springs in the vicinity. Valencia is finely situated in an exceedingly fertile district, in which cattle and horses are raised in great numbers. Pop. '88, 38,654.

VALENCIENNES, a manufacturing t. and fortress of France, in the department of Nord, on the Escaut, 155 m. by railway n.e. of Paris. It is well built, but it does not contain many objects of attraction of any sort. There are many pleasant promenades in the immediate vicinity. A famous kind of lace is made here, as well as fine woven fabrics and gauzes. There are foundries, rolling-mills, and machine shops. Salt-making and sugar-refining are carried on, and there is an active trade in timber, wine, and oil. It is the birthplace of Watteau and Froissart. Pop. '91, 21,698.

VALENS, Emperor of the East, the brother of Valentinianus I. (q.v.), was born near Cibalis in Pannonia, about 328 A.D., and was associated with his brother in imperial authority, receiving as his share of the empire, Asia, Egypt, and Thrace, March 28, 364. His sovereignty was, however, disputed by Procopius, a supposed scion of the race of Constantine, who raised his standard in Thrace, was crowned at Constantinople, and for two years maintained his ground with skill and courage, till the defeat of his troops at Thyatira and Nacosia, and his subsequent capture and cruel death, 366 A.D. The first prominent act of Valens's reign was a reduction of 25 per cent in the taxes, which gained him the general good-will of his subjects, but was of questionable prudence in the unsettled state of the northern and eastern frontiers. The prolonged imprisonment of 3,000 Ostrogoths, who had been sent to aid Procopius, led to a rupture between Valens and the aged hero Hermanric, and to a war which lasted from 367 to 369. The contest was carried on in the country of the Goths, and was throughout in favor of the Romans. Difficulties arose immediately afterward (370) with the Persians, who were desirous of possessing themselves of Armenia, and though the two powers came frequently into collision, the one as the assailant, and the other as the ally of the Armenian monarch, war was not declared till the end of 372, when the Romans were victorious. Valens, who had removed to Antioch at the commencement of the war, now occupied himself with the religious quarrels between the Arians and the orthodox party, which at that time raged with much violence over the whole eastern empire. Incapable of independent judgment, he had adopted the views of his Arian councilors, and under their guidance, punished the more obstinate of the "heretics." At the same time, a conspiracy, prompted by professors of magical arts, who declared that Valens's successor should be one whose name began with *Theod*, was discovered, its promoters and agents punished with death, as well as a number of persons who were so unfortunate as to possess a name commencing with the unlucky prefix. Affairs on the eastern frontier again assumed a threatening aspect; but the Romans were disinclined any longer to interfere with the designs of the Persians on Armenia, and concluded a somewhat discreditable treaty in 376. In the mean time, events were taking place on the northern frontier which were destined ere long to become of sinister import to the Roman empire. The Goths, who had for some time been peacefully settled in Dacia, were assailed by the advancing hordes of the Huns; the Ostrogoths, who first felt the shock, were partly incorporated, and the remainder forced to retreat; the Visigoths next attempted to stem the torrent, but without success, and immense crowds of fugitives belonging to this warlike race crowded to the n. bank of the Danube. Valens accorded permission to a large body of Goths under Fritigern to cross into Mœsia and Thrace, and take possession of the waste lands in these provinces; the fugitive Ostrogoths soon afterward crossed the river without permission; and the alarm which the numbers and turbulence of his new subjects speedily aroused led Valens to the adoption of such impolitic measures, that the gratitude of the Goths for shelter afforded was turned to bitter resentment. Valens, prompted by his servile and flattering advisers, at last resolved on war; and marching against the barbarians, he engaged them near Adrianople, Aug. 9, 378. His

army was totally routed, and two-thirds of it, including Valens himself and most of his chief officers, left dead on the field.—See Gibbon's *Decline and Fall*, chaps. 25 and 26; Tillemont's *Histoire des Empereurs*, vol. v.

VALENTINE, Basil, a celebrated German alchemist, of whom so little is known that it has been disputed whether he flourished in the 12th or the 15th century. It has been maintained that he was a monk of the order of St. Benedict, in St. Peter's convent at Erfurt, but his name does not appear on the list at Erfurt, nor on the general list kept at Rome. It seems probable that he flourished about the end of the 15th century. He was a diligent seeker for the philosopher's stone, and wrote a large number of works, chiefly on the process of transmutation, a complete list of which will be seen in Lenglet's *History of the Hermetic Philosophy*, vol. iii. Some of the titles are curious, as *Basil Valentine's Twelve Keys of Philosophy; Apocalypsis Chymica; Revelation of the Mystery of the Essential Colors of the Seven Metals; The Triumphal Car of Antimony; A Chemico-philosophical Tract concerning Things Natural and Preternatural*, etc. After his death, his works were thought to be wholly lost, when they were discovered in the stonework of the abbey, "heaven itself conspiring to bring to light these extraordinary works by shattering by a thunderbolt the pillar in which they were concealed," if we are to believe his followers in the mystic art, who have handed the story down to us. His works were mostly written in the old Upper-Saxon dialect, and were not printed till 1602; after which time many of them were published in the form of French translations, though a few still remain in MS.

VALENTINE'S DAY, the 14th of February, is, or more correctly was, celebrated in England, Scotland, and in different parts of the continent, particularly Lorraine and Maine in France, by a very peculiar and amusing custom. On the eve of St. Valentine, a number of young folk—maids and bachelors—would assemble together, and inscribe upon little billets the names of an equal number of maids and bachelors of their acquaintance, throw the whole into a receptacle of some sort, and then draw them lottery-wise—care, of course, being taken that each should draw one of the opposite sex. The person thus drawn became one's valentine. Of course, besides having got a valentine for one's self, one became, by the universality of the practice, some other person's valentine; but, as Misson, a learned traveler in the early part of last century, remarks, "the man stuck faster to the valentine that had fallen to him, than to her to whom he had fallen." These imaginary engagements, as may readily be supposed, often led to real ones; because one necessary consequence of them was that, for a whole year, a bachelor remained bound to the service of his valentine, somewhat after the fashion of a mediæval knight of romance to his lady-love. At one period it was customary for both sexes to make each other presents, but latterly the obligation seems to have been restricted to young men. During the 15th c. this amusement was very popular among the upper classes, and at many European courts. From Pepys's *Diary*, we see that in Charles II.'s reign, married as well as single people could be chosen.

For some time back, the festival—at least in England and America—has ceased to possess the graceful symbolic meaning it used to have, and has become a considerable nuisance. The approach of the day is now heralded by the appearance in the stationers' shop-windows of vast numbers of missives calculated for use on this occasion, each generally consisting of a single sheet of paper of the cheapest kind, on which is seen some ridiculous-colored caricature of the male or female figure, with a few burlesque verses below. More rarely, the print is of a sentimental kind, such as a view of Hymen's altar, with a pair undergoing initiation into wedded happiness before it, while Cupid flutters above, and hearts transfixed with his darts decorate the corners. Maid-servants and young fellows interchange such epistles with each other on the 14th of February, no doubt conceiving that the joke is amazingly good; and, generally, the newspapers do not fail to record that the city postmen delivered so many hundred thousand more valentines on that day than they do in general.

The connection of the custom with St. Valentine is purely accidental. In the legends of the different saints of that name recorded in the *Acta Sanctorum*, no trace of the practice peculiar to the 14th of February is found. It has been suggested by Mr. Douce, in his *Illustrations of Shakespeare*, that the custom may have descended to us from the ancient Romans, who, during the *Lupercalia*, celebrated in the month of February, were wont, among other things, "to put the names of young women into a box, from which they were drawn by the men as chance directed;" and that the Christian clergy, finding it difficult or impossible to extirpate this pagan practice, gave it at least a religious aspect by substituting the names of particular saints for those of the women; and it is certainly a usage more or less widely extended in the Roman Catholic church to select, either on St. Valentine's day or some other, a patron saint for the year, who is termed a valentine. But it is far more probable that the custom of choosing valentines is a relic of that nature-religion which was undoubtedly the primitive form of religion in n.w. Europe—as elsewhere; and that it sprung from a recognition of the peculiarity of the season. Hence the explanation, that "about this time of the year the birds choose their mates, and thence probably came the custom of the young men and maidens choosing valentines or special loving friends on that day." Valentines are now less extensively manufactured than formerly.

VALENTINIANS, a gnostic sect or school (see GNOSTICS), founded by Valentinus, who went from Alexandria to Rome about 140 A.D., and died there, or in Cyprus, about 160. The distinguishing feature of his system lies, in the first place, in his recognizing heathenism as a preparatory stage of Christianity; and then in his dividing the higher spiritual world into 15 pair of æons, each consisting of a male and a female. The first pair, or syzygy, is made up of Bythos, or God in himself, and Ennoia, or God as existing in his own thoughts; from these emanated next Nous (Intelligence) and Aletheia (Truth), and so on. As the last æon, Sophia, transgressed the bounds that had been laid down by the æon Heros, and a part of her being became lost in Chaos, there was formed a crude being, called Achanroth, which, through the Demiurgos that emanated from it, created the corporeal world. Heros now imparted to the souls of men (for all the bodies composing the corporeal world are possessed of souls) a *pneumatic* or spiritual element, but this only attained to full activity when Christ, a collective emanation from all the æons, appeared as Saviour, and united himself with the man Jesus. In the end, all that is pneumatic, and even the originally psychic or soul element in as far as it has assimilated itself to the psychic, will return into the Pleroma.

VALENTINIA'NUS, the name of three Roman emperors of the same family; the first and most famous of whom, VALENTINIANUS I., was the son of a Gratianus (a ropemaker who had enlisted in the army, and risen to the grade of *comes militum*), and was born at Cibalis, in Pannonia, 321 A.D. Valentinianus entered the army at an early age, and, aided by the military renown of his father, rapidly rose in rank under the emperors Constantius and Julian, only, however, to fall more rapidly; for he was degraded by Constantius in 357, and, for his publicly expressed contempt for paganism, banished by Julian in 362. Restored to favor in the following year, he distinguished himself in the e., and on the death of Jovian, was unanimously chosen as his successor, Feb. 26, 364. A month after his accession, he chose as his colleague his brother, Valens (q.v.), to whom he resigned the government of the e., reserving for himself Illyricum, Italy, the Gauls, Britain, Spain, and Africa. During VALENTINIANUS's reign, the utmost vigilance was required to preserve the frontier districts of the empire from the ravages of the swarms of barbarians who, like vultures, had gathered round their prey, watching with greedy eagerness the rapid decay of its strength, and ready at the first opportunity to hasten its impending doom. The Alemanni repeatedly (366–68) ravaged the e., and the Saxons (370) the north-east of Gaul; Illyricum was wasted (370) by the Quadi, and Africa by the southern desert tribes; and though these invasions were mostly repelled and revenged in a manner becoming the warriors of the queen of nations, the auxiliary means often had recourse to (e.g., the assassination of two powerful and able opponents, the kings of the Alemanni and Quadi, and the treacherous attack on the Saxons while under the fancied security of a treaty), surely indicated that the sturdy virtue which formerly imbued the soldiers of the empire was rapidly disappearing. The internal administration was excellent, for the emperor added to his ability, prudence, and firmness of character, the less common imperial qualities of vigilance and impartiality; and his cognizance of any abuse or injustice by whomsoever perpetrated, was the signal for its speedy rectification, and the severe punishment of the offender. Though himself a zealous Catholic, he repelled the solicitations of the bishops who wished him to interfere in the religious disputes of the time, permitted his subjects to adopt whatever religion they chose, and strictly forbade all persecution or annoyance on account of religious belief, even retaining the "pontifices" of the provinces in the privileges which they had possessed under Julian. On account of the scandalous abuse by ecclesiastics of their influence over their penitents, he excluded priests and monks from the right of succession to property; judicial proceedings were forbidden to be held in private; the extreme license of speech hitherto allowed to advocates was judiciously restrained; gratuitous medical attendance was provided for the poor of Rome; and schools were established throughout the empire. The success of VALENTINIANUS's administration was doubtless much owing to his fortunate choice of officers: Theodosius the elder in Africa and Britain, Jovinus in Gaul, and Theodosius the younger (afterward emperor) in Illyricum, form a trio distinguished by an unswerving loyalty, administrative ability, and miltary talent, rarely found in any age; and contrast strongly with their predecessors in office. VALENTINIANUS's private life was a model of morality and economy; and according to the summation of the accurate and trustworthy Ammianus, "he had so many good qualities, that if everything had been equal in him, he would have been another Trajan or Marcus Aurelius." But the one and grievous fault which marred his character was an ungovernable temper, which led him into the occasional commission of excessive cruelties, and ultimately caused his death; for while giving audience to the deputies of the Quadi, with whom he was then at war, he worked himself into such an access of passion as to rupture a blood-vessel in his chest, and fell back dead into the arms of his guards, Nov. 17, 375. By his first wife he had one son, Gratianus (q.v.); and by the second, Justina, another son, Valentinian, and three daughters, one of whom, Galla, became the wife of the emperor Theodosius I.—VALENTINIANUS II., the younger son of the preceding, was born 372 A.D., and received from his elder brother, Gratianus (q.v.), the provinces of Italy, Illyricum, and Africa, as his share of the western empire. During his long minority, the empress Justina,

administered the government; and about three years after her death, Valentinianus, who had given promise of good administrative qualities was murdered by the Frank, Arbogastes, the commander-in-chief of his army, May 15, 392.—VALENTINIANUS III., the grand-nephew of the preceding, being the son of Constantius III. by Placidia, the daughter of Theodosius the great and Galla, was born about 419 A.D. and was seated on the throne of the west by Theodosius II., emperor of the east, 425 A.D. Valentinianus was a weak and contemptible prince, nevertheless his reign is one of the most interesting epochs of Roman history, exhibiting, as it does to the full, the internal weakness and corruption of the empire, the gradual closing with it of its irresistible barbarian foes; the sad picture being momentarily lightened from time to time with a flash of the warrior-spirit of old Rome. Valentinianus may be said never to have ruled during the 30 years that he sat disesteemed and unhonored on the imperial throne; his mother, Placidia, governed till her death in 450, and was succeeded by the eunuch, Heraclius, one of those malignant fribbles who swarmed around the throne of the falling empire. The regulations enacted for the internal administration were creditable, and especially so when ecclesiastical interests were involved, as in almost all cases, the ambitious and persecuting tendencies of the now preponderant orthodox party, were firmly restrained; while, on the other hand, the fierce vindictiveness of its more bigoted rivals was kept within bounds. But the utter corruption of manners, the complete extinction of "public spirit," the oppressive exactions of the tax collectors, and equally of the commissioners who were appointed to prevent these exactions; the general employment of the powers of the executive in the avenging of private quarrels, and the utter impossibility of obtaining redress for injuries, too plainly showed that the empire had fallen far beyond remedy, and that if not destroyed by assailants from without, it would speedily crumble to pieces of itself. The early part of Valentinianus's reign was disturbed by the contests between the "comites" Boniface and Aëtius, the former of whom had supported, and the latter resisted Valentinianus's claims to the throne; but notwithstanding this, the vile and groundless calumnies of Aëtius prevailed upon the empress to declare the gallant and upright governor of Africa a public enemy; and the latter, in the first flush of resentment, called to his aid the Vandals under Genseric (q.v.). Thus Africa was lost to the empire. But Aëtius, notwithstanding, proved himself the invincible bulwark of the Roman power in Europe; the Franks, Goths, Burgundians, and other German nations who had encroached on the empire, were successively defeated and repelled, and the destructive career of the formidable Huns brought nigh to a close on the field of Chalons. Yet the labor of defending an extensive empire from attack on all sides was too much for one man; and consequently, much of Spain and Gaul was ultimately seized by the Suevi and Visigoths, the n. of Italy was ravaged by the Huns, Sicily and Sardinia by the Vandals, and even Rome repeatedly besieged, while Britain was abandoned to the wild Picts and Scots. Aëtius seems to have committed the same error as his more upright and noble, though not more able, predecessor Stilicho (q.v.), in attempting, by the marriage of his son to Valentinianus's daughter, to transfer the imperial dignity to his own family, and like him also, undermined in influence and reputation by the machinations of a eunuch, he was assassinated, though by the sword of his master (454). In the following year, Valentinianus was conspired against by the friends of Maximus and the faithful adherents of Aëtius, and murdered, March 16.

VALENZA, *Valentia, Valentinum Forum*, a city of northern Italy, province of Alessandria, on the right bank of the Po, 9 m. n. of Alessandria. It is very regularly built, and commands a fine view of the surrounding vine-clad hills. It carries on a trade in wine, and manufactures of silk, flax, and hemp fabrics. Pop. abt. 6500.

VALERA JUAN, Spanish novelist and diplomat, was born in the province of Cordova, Oct. 18, 1824. After a thorough education, his aristocratic connections enabled him to embrace a diplomatic career. *Pepita Jiminez*, his first novel, appeared in 1874, and "was a success unparalleled in the history of modern Spanish literature." It has been translated into English. Among his later novels are *El Comendador Mendoza*, *Doña Luz* and *Doctor Faustino*. Valera has also produced many excellent critical studies. For several years he represented Spain in Washington and elsewhere, subsequently becoming a senator and member of the council of state. In 1893 the Pope declined to receive him as the envoy of Spain at the Vatican because of his *Pepita Jiminez*.

VALE'RIAN, *Valeriana*, a genus of plants of the natural order of *valerianaceæ*, an order of exogenous plants, containing nearly 200 known species, natives of temperate climates, chiefly of Europe, the mountainous parts of India, and South America; annual or perennial herbaceous plants with opposite leaves, destitute of stipules, and small flowers in cymes. They are nearly allied to *dipsacaceæ* (see TEASEL), but differ in the mode of inflorescence, and in the seeds being destitute of albumen. The fruit also is not simply 1-celled, but exhibits two other abortive cells, and the stamens are 1–5, the stigmas 1–3. The corolla is sometimes spurred.—The genus *valeriana* is distinguished by a pappus-like calyx, a spurless corolla, and three stamens. The species are pretty numerous. The common valerian (*V. officinalis*) is abundant in ditches, moist woods, etc., in Britain and throughout Europe. It has a fleshy root, pinnatifid leaves, a stem 2–4 ft. high, and pale flesh-colored flowers. The root is a well-known medicine, used both by physicians and as a domestic remedy in spasms, epilepsy, hysteria, and other nervous affections. It possesses powerful antispasmodic properties, and a very considerable influence over the nervous system. Cats are very fond of it, and it exercises a

remarkable stimulating and intoxicating power over them. Although the plant grows chiefly in damp soils, the root is most powerfully medicinal in dry hilly ground.

The roots should be collected in autumn; and those from wild plants growing on a dry soil are preferred. The chief ingredients of valerian are woody fiber, resinous and gum-like matters, and a little more than one per cent of a volatile oil, which is crystallizable, and has been termed *valerole*, and in which a well-known acid (also obtained from several other sources), *valerianic* or *valeric acid*, is developed on exposure to the air. Valerian imparts its therapeutic properties, which are those of a stimulating antispasmodic agent, both to water and to alcohol. There are three officinal preparations—viz., the *infusion*, the *tincture*, and the *ammoniated tincture*. In large doses, valerian produces considerable disturbance of the nervous system, as headache, vertigo, and even temporary blindness. In average doses—as, for example, in from one to two ounces of infusion, and from half a dram to two drams of either of the tinctures—it is a very efficacious remedy in those severe cases of hysteria which closely simulate epilepsy, and in chorea. As some of the salts of valerianic acid—viz., the valerianates of soda, zinc, ammonia, iron, and quinine—act similarly to and with more certainty than the above-named preparations, we may infer that the therapeutic action of the remedy is solely due to the acid; and as the infusion and tinctures are by no means agreeable medicines, they will probably soon be replaced by the valerianates.

The Small Marsh Valerian (*V. dioica*), also a native of Britain, is much less powerful than the common species.—The greater valerian (*V. phu*), which grows in alpine districts of the continent of Europe, is now almost entirely disused, although it is said to be one of the strongest of the European valerians, a pre-eminence which *V. dioscoridis* disputes with it.—*V. Celtica* and *V. saluinca* are gathered near the limits of perpetual snow on the mountains of Styria and Carinthia, and carried into Turkey and Egypt, and thence into India and Ethiopia, to be used to aromatize baths, and as a substitute for Spikenard (q.v.).—*V. sitchensis*, a native of the n.w. of America, is said to possess the medicinal properties of the genus in great perfection. *V. Hardwickii* is used medicinally in Nepaul.—The root of *V. edulis*, a species found in the n.w. of America, is an article of food of the Indians.—Corn salad (q.v.) or lamb's lettuce belongs to the order *valerianaceæ*.

VALERIANEL'LA. See Corn Salad.

VALERIA'NIC or Valeric **ACID** is one of the volatile fatty acids represented by the general formula $C_nH_{2n+1}\cdot CO_2H$, or $C_nH_{2n}O_2$. Its composition is represented by the formula $C_4H_9\cdot CO_2H$; and among its chief properties it may be noticed that it is a limpid, colorless, oily fluid of a penetrating odor, allied to that of valerian root, and an acrid taste. It renders paper transparent, but the spots disappear on exposure to the air. Its specific gravity is 0.94, it boils at 347° F. (175° C.), and may be distilled without change; and its vapor is inflammable. It is only slightly soluble in water, but dissolves in alcohol and ether in all proportions. It exists in and is obtained by distilling valerian root with water acidulated with sulphuric acid. It may be similarly obtained from angelica root, and some other vegetable sources. It is also formed during the oxidation of fats and fatty acids (especially oleic acid), either by nitric acid or mere exposnre to the air, by the oxidation and putrefaction of the albuminates, etc., but the best method of procuring it is by distilling a mixture of amylic alcohol (or fusel oil) with bichromate of potash and sulphuric acid.

The salts of valerianic acid—the valerianates or valerates, as it is now becoming the fashion to call them—are formed either by saturating the base or its carbonate with the free acid, or by double decomposition, their general formula being $C_5H_9O_2\cdot M$, when M is any metal. The alkaline valerianates are very soluble, and are not easily obtained in crystals; but most of the other salts occur in nacreous scales, and all of them, when moist, have the smell and taste of valerian.

The following salts are used in medicine: *valerianate of soda*, which is included in *pharm. Br.* *valerianate of zinc*, which is also included in *pharm. Br.*, and occurs in brilliant white pearly tabular crystals, with a feeble odor of valerianic acid and a metallic taste, is scarcely soluble in cold water or in ether, but insoluble in hot water and alcohol. Besides these officinal salts, the valerianates of ammonia, of iron, and of quinia are employed in the same cases as the preparations of valerian, the doses averaging from half a grain to three or four times that amount three times a day in pills, except in the case of the ammonia salt, which is best given in solution. *Amyl valerianate*, $C_5H_{11}\cdot C_5H_9O_2$, is a volatile fluid with a penetrating odor of apples, boiling at about 374° F. (190° C.), slightly soluble in water, but dissolving freely in spirit and in ether. In the form of a dilute spirituous solution, it so strongly resembles apples in its smell that it is used in perfumery under the title of *oil of apples*.

VALERIA'NUS, P. Licinius, Roman emperor, was descended from an ancient and noble family, and after distinguishing himself in the various posts which he was selected to fill by masters who appreciated his talents and virtues, was chosen for his integrity and accomplishments to the office of censor. Faithful in his allegiance to Gallus, he went to summon the legions of Gaul and Germany to aid the feeble emperor against the usurper Æmilianus, but arrived too late to save his master. The usurper's troops, awed by the superior numbers of Valerianus's army, and the stern sanctity of their leader's

character, murdered their own chief, and united with their late antagonists in proclaiming Valerianus emperor, 253 A.D. Valerianus was then about 60 years of age, and feeling his inability to sustain, unaided, the cares of empire, assumed as colleague his eldest son, Gallienus (q.v.). Valerianus showed abundant proof during his short reign of most ardent zeal for the prosperity of the empire; but the times required a ruler of more energy and ability; as the grave disturbances which arose throughout the empire, the irresistible irruption of the Franks into Gaul, despite the utmost efforts of Aurelianus (q.v.), the devastation of Thrace, Macedonia, Greece, and the archipelago by the Goths, the advance of the Alemanni to Milan, and the conquest of Syria and Armenia by Shapur, amply testified. The troubles in the e. appearing most threatening, Valerianus went thither in person, and for some time fortune favored his standard; but pursuing his opponents too rashly, he was suddenly attacked by superior numbers at Edessa, completely defeated, and himself, with the remnant of his army, forced to surrender, 260 A.D. The statements regarding the indignities heaped upon the unfortunate captive by his haughty conquerer, are probably false, or, at least, much exaggerated; but of one thing we are assured, that Valerianus languished till death in hopeless captivity; and after his death, his skin was flayed off, stuffed, preserved as a proud trophy of victory, which was invariably exhibited to the ambassadors from Rome to the Sassanide court.

VALERIEN, MONT, is an eminence west of Paris, rising some 350 feet above the Seine, and crowned by one of the strongest of the fortifications of the city. Mont Valerien was a most important factor in the sieges of Paris, during the Franco-Prussian War. This eminence was formerly the site of a monastery, known as Le Calvaire, that was erected during the reign of Louis XIII., and was a favorite resort for pilgrims. Whittier refers to this eminence in his poem entitled *The Chapel of the Hermits.*

VALERIUS MAXIMUS, a Roman historical compiler of the reign of Tiberius, his work bearing the title of *Factorum et Dictorum Memorabilium,* Libri IX, and consisting of short stories and anecdotes from various authors. His style is ornate and often obscure, and his want of acquaintance with the history and constitution of his country renders him an unsafe guide; yet he was a favorite author of his own time, and much studied in the middle ages. The best edition is that of Kempf, Leipsic, 1888.

VALET'TA, an important fortress and beautiful city, capital of the island of Malta, on the n.e. side of which, in lat. 35° 53′, long. 14° 31′, it is situated. It occupies a tongue of land, which runs out in a n.e. direction, is 3,200 yards long, and generally about 1200 yards across, except at the extremity, where it narrows considerably, and forms the famous point of St. Elmo, on which are a powerful fort and a light-house. From this point to its landward end, the neck of land, which is well named the "Hog's Back," rises gradually; and there is a downward slope from the central ridge to the Great harbor on the right, and to the Marsa-Musceit, the quarantine harbor, on the left. Eight principal streets traverse the peninsula, and are intersected by cross-streets, that pass ever the central ridge, and afford communication from harbor to harbor. These cross-streets are necessarily very steep at the extremities, where they rise from the shores by long flights of stairs. The town and harbors are defended by a series of fortifications of great strength. They are mostly hewn out of the solid rock, and, mounted with the most powerful artillery, are considered impregnable. Besides the enormous forts, balconies, and battlements, which are the principal architectural characteristics of the city, Valetta contains many noble edifices. The governor's palace—formerly that of the grand masters—is unadorned without, but magnificent within, and possesses an interesting armory; the cathedral of St. John is a superb structure. There are also a university and a library, founded by the knights. Pop. '91, with suburbs, 62,152. See MALTA.

VALETTE, JOHN PARISOT DE LA, a grand master of the knights of St. John, celebrated for his gallant defense of Malta against a powerful fleet of the Turks, which must be regarded as mainly instrumental in checking the westward progress of the arms of Solyman the great, long the terror of Europe and of Christendom. La Valette was born of a noble family, in 1494; and at a very early age entered the order of St. John, in which he soon distinguished himself by his enthusiastic bravery and his skill in arms. His chief distinctions, even in youth, were won in the naval service in the Mediterranean, where the Turkish power was especially formidable. On the death of Claude la Sangle, grand master of the order, La Valette was elected to that office, being the 48th in the list of the grand masters. Still directing the energies of the order in the same course, he succeeded, within the first five years of his grand-mastership, in capturing 50 great galleys from the Turks, and an immense number of smaller vessels of war; a success which so stirred the indignation of the sultan, that he resolved on the capture of Malta, and the destruction of the knights. Accordingly, on May 18, 1565, an immense fleet, of 159 ships, conveying a body of 30,000 janizaries and spahis, appeared off the harbor of Malta, and after failing in several assaults, formally invested the island. Alone and unsupported by any of the Christian powers, the gallant La Valette maintained the fortress under circumstances of extreme difficulty and distress of every kind; and when, all further resistance seeming to be hopeless, he was urged to capitulate, his reply was, that the life of a worn-out soldier of 71 years could not be better spent than in such a service. At last, at the end of four months, and after a loss, it is said, of 20,000 men,

the Turkish fleet was forced to raise the blockade and withdraw from the island. La Valette died three years later, Aug. 21, 1568.—There is another La Valette, a father of the Jesuit society, who obtained a very different sort of notoriety in the latter half of the 18th century. Having engaged, contrary to the prohibition of Benedict XIV., as a trader in the products of the large estates held by the Jesuits in the Philippine islands, and being unable, in consequence of the capture of his ships by an English privateer, to meet his engagements, a suit was commenced in the French courts against the French province of the society, the proceedings in which suit were among the causes which precipitated the expulsion of the society from France, and its eventual suppression by Clement XIV. See Jesuits.

VALGUARNE'RA, a t. of Sicily, in the province of Caltanisetta, 48 m. n.e. of Girgenti, in a mountainous district. Pop. about 11,500.

VALGUS is a term employed in surgery to designate a variety of club-foot (q.v.). The corresponding Latin word signfies "having legs bent outward, bow-legged," and is probably derived from *volvo*, "to turn or twist." As it is an adjective, the substantive, *talipes* (an unclassical word, indicating "weakness of the feet," but in surgical nomenclature signifying "club-foot") must be regarded as understood.

VALHALLA. See Walhalla.

VALLA, Laurentius, one of the first scholars of the renaissance, was b. at Rome in 1407, taught classics in various places in the north of Italy; but in 1443, on account of his assaults on the scholastic philosophy, and his defense of Epicurus, found it advisable to seek protection at Naples from Alfonso V. Here, however, he soon fell under a suspicion of heresy, and was, it is said, dragged for punishment before the inquisition. Aided by the king, he made his escape, and fled to Rome, where Pope Nicholas V. pardoned him, received him into favor, and appointed him papal secretary and canon in the church of St. John Lateran. He died 1457. Valla's Latin translations of Herodotus (Par. 1510) and Thucydides (Lyon, 1543) are admirable, and had a great influence in spreading a knowledge of classic history; but the work that brought him most renown was the *Elegantiæ Latini Sermonis* (6 books; Rome, 1471), which long served as a model in style to Latinists. From 1471 to 1536, no fewer than 59 editions of it appeared. It has passages of noble eloquence in praise of the glorious tongue of Rome, through which one discerns a passionate desire for the unity of Italy—that now attained aspiration of Italian scholars and writers. The *Elegantiæ* is, moreover, full of nice grammatical observations, particularly on synonyms. Valla has also the credit of being the first of the renaissance scholars that used his classical culture in the criticism of the New Testament (*Annotationes in Novum Testamentum*, published by Erasmus). In his *De Donatione Constantini Magni*, he demonstrated the historical groundlessness of the pretended "Donation" of Constantine, and inveighed against the popes for their grasping after temporal power; but this he was forced to retract. A collected edition of Valla's works appeared at Basel in 1543. See Symonds, *The Renaissance in Italy* (Amer. ed. 1881).

VALLADOLID', a famous city of Spain, sometime capital of the whole country, and still capital of the province of the same name (see Castile), stands on a wide, wind-blown plain on the left bank of the Pisuerga, 150 m. n.w. of Madrid by railway. It is 2,100 ft. above sea-level, and has a healthy climate, the air being pure and genial, and the sky generally cloudless. Having been the residence of the court prior to its removal to Madrid at the close of the 16th c , the city contains many large and decayed dwellings; although, with the returning prosperity of the town, new mansions are being erected, and the streets are being paved, enlarged, and multiplied. In the plaza de Campo, the site of famous tournaments, *autos-da-fé*, decapitations, and bull-fights, Napoleon reviewed 35,000 troops. The university, founded in 1346, is attended by about 900 students. The Museo, which contains such of the statues, carvings, and sculptures as could be collected at the suppression of convents in the province, is an elegant building, containing a grand saloon, six rooms filled with pictures, and three with sculptures. Of these treasures, the sculptures are the most valuable, though among the pictures are several by Rubens. The university, long celebrated as a seat of learning, was founded in 1346. Near the palacio real (royal palace), are the remains of two of the noblest Gothic religious edifices in the world, the convent of San Pablo, and the Colegio de San Gregorio, both richly and beautifully decorated, but much damaged by the French soldiery. Valladolid is admirably situated for trade and manufactures. There is abundant water for irrigation, and the surrounding district is remarkably fertile. It communicates with the Atlantic by the Douro, and with the middle and south of Spain by canals and railways. Manufactures are springing up in the city; the soil in the vicinity is being improved by companies instituted for that purpose; and in other respects Valladolid gives tokens of revival. Silk, cotton, and woolen stuffs, jewelry, hats, paper, perfumery, etc., are manufactured, and there are iron foundries. Pop. '87, 62,018.

Valladolid, the *Pincia* of Ptolemy, is first mentioned under its present name in 1072. Charles V. erected many splendid edifices here. About this time Valladolid was the most prosperous city in Spain, containing 100,000 inhabitants. Formerly capital of Castile and Leon, it was still the residence of the kings and the usual resort of foreigners. In 1560 Madrid was declared the only court; and from this time the prosperity of

Valladolid declined. Since 1851 it has been the seat of an archbishop, and has still its university.

VALLADOLID′, a t. of Mexico, in the state of Yucatan, 100 m. s.e. of Merida, stands in the midst of a highly cultivated tract of country. It is the best constructed and the healthiest town in Yucatan, and the seat of cotton manufactures. Pop. about 14,000.

VALLAN′DIGHAM, Clement Laird, 1820-71; b. Ohio, of Huguenot ancestry; spent a year at Jefferson college, Ohio; principal two years of an academy in Maryland; admitted to the bar, 1842; member of the legislature, 1845–46; editor of Dayton *Inquirer* 1847–49; member of congress, 1857–63; bitterly assailed the measures of government for the suppression of the civil war; was arrested by order of Gen. Burnside; tried by court-martial, and sentenced to close confinement during the war; but the sentence was commuted by President Lincoln to banishment beyond the lines of the army. He escaped to Canada, was nominated governor of Ohio by the democratic party, but was defeated by 100,000 votes; was a delegate to the Chicago convention, 1864. He died by the accidental discharge of a pistol in his own hand.

VALLE, Pietro della, 1586–1652, an Italian traveler, was b. in Rome, but removed to Naples in 1614 and started on a journey to the orient, visiting Turkey, Egypt, Arabia, Persia, and India, where he made a study of the customs and languages of the various people. After eleven years of wandering he returned to Rome, bringing with him many trophies of his journey. He left an account of his travels, which was published at Rome in 1650–58.

VALLE DI RENDENA, a picturesque valley in southern Tyrol, on the upper Sarca, much visited by travelers for its fine mountain scenery. The Adamello, Brenta, and Presanella groups of the Alps can be viewed, and the way to the Madonna di Campiglio lies through the valley. It is well populated and the inhabitants are engaged in the culture of silk and of mulberry trees, and in the rearing of cattle. Many of them travel as scissors and knife grinders to Austria and Italy.

VALLEJO, a city in Solano co., Cal.; on San Pablo bay and the Southern Pacific railroad; 24 miles n.e. of San Francisco, and directly opposite the U. S. navy yard on Mare island. It has an excellent harbor, accessible to vessels of the largest draught, and is principally engaged in agriculture and manufacturing, the latter including ships, machinery, and terra-cotta work. There are electric lights, national and state banks, orphan asylum, high school, St. Vincent's convent school, public library, daily and weekly newspapers, and large grain-shipping interests. Pop. '90, 6,343.

VALLEY, a hollow tract on the earth's surface between hills or mountains. Valleys are generally parallel to the direction of the ridges of elevated ground; but some are transverse, cutting through the mountain-chain. They have a watercourse at or near their lowest level. The main valley is that which has the river of the drainage-system to which it belongs flowing through it, while the tributary streams which feed this river flow through lateral valleys. The terms upper and lower valley define parts of the same valley, as related to the source or to the mouth of the river which flows through it. In a narrow valley, the river always occupies the lowest part; but in wide valleys, especially in those in which waters run that are largely charged with sediment, the river often builds up a channel for itself, that is higher than the ground at the foot of the hill. The river, in its floods, bears a large amount of mud, which it continues to carry as long as the water is retained within its bed; but whenever it overflows its banks, the velocity is reduced, and the heavier particles, which form the bulk of the sediment, are deposited near the river's course; while, flowing over the surface of the level ground, the finer particles fall to the bottom, until, as it reaches the limits of the valley, the water gradually becomes clearer. The Rhine, the Nile, and indeed almost all great rivers in wide valleys, illustrate this phenomenon. The river seldom flows through the middle of the valley, but is generally nearest to that side where the slope to the high ground is steepest; the opposite side of the main valley presenting a more gradual rise to the mountain summits, supplies the chief lateral valleys and feeding-streams to the river.

The origin of valleys has been a subject of considerable controversy, and this question continues to occupy the attention of geologists. At the time when a universal deluge was used to explain whatever was inexplicable in geology, it was considered to have been the agent which furrowed the earth's surface with valleys; and this opinion was entertained so lately, as to have been advocated by the late Dean Buckland in his *Reliquiæ Diluvianæ*, until Prof. Fleming showed the untenableness of these opinions.

At the present day, geologists are very much divided as to the origin of valleys. Some hold that they are the result of the operation of that internal agency which has, at different periods, so broken the crust of the earth, and changed its surface; while others maintain that various agents now operating more or less favorably in disintegrating and removing the solid materials of the exposed portion of the surface of the earth, produced the inequalities that now exist. There can be no doubt that all these have been active, and that the special advocacy of individual agents, as the sole producers of these phenomena, is the source of error, and the cause of controversy. Each and all have done their part; and in a satisfactory explanation, they must all be taken into account. That internal force has been a principal agent in producing the diversity

of hill and valley, seems beyond doubt. This force acted by raising the surface perpendicularly from below upward; by producing great faults, which presented facilities for the action of running water; or by pushing a portion of the crust forward, so as to produce immense folds, alternating with mountain ranges. The Appalachians of North America, and the associated valleys, have been produced, as has been shown by prof. Rogers, by the last-mentioned method; and the tertiary strata of the Alps were carried up a 1000 ft., while the valley-beds of the Adriatic and the Mediterranean either remained stationary or subsided to a lower level. The fact that some valleys are only the synclinal axes between the bounding mountain systems, like the basin of Switzerland between the elevated ridges of the Alps and the Jura, also confirms the opinion that some valleys owe their origin to the operations of an internal force, which operated in geologic ages in a more powerful manner than it has been known to do in historical times. In the face of such facts, it is surprising to hear practical geologists so influenced by pet theories as to assert that the action of internal force has "no direct effect on the external features of the ground." But this is the position of men who adhere to the strict Lyellian doctrine, that all the past changes on the earth's surface have been produced by agents now operating, and at the same rate, but through enormously protracted periods of time. But as these agents are various, so we have almost as many theories as there are agents. Lyell insists that ocean currents, and the wear and tear of the waves, have produced the inequalities. Jukes will have it that the atmosphere has disintegrated, and the rivers carried off the materials which formerly filled up the hollowed-out valley to a level with the surrounding hills; while Ramsay declares that glaciers were the important agents in the process. While the advocates of superficial agents so completely ignore the influence of internal force, as in the statement of prof. Jukes quoted, those who maintain the opposite view are equally open to condemnation when they declare that "the wear and tear due to atmospheric sub-aërial erosive agency never could, even after operating for countless ages, have originated and deepened any of the valleys which occur in flat countries." — Murchison's address at British Association, 1865.

VALLEY, a co. in central Nebraska, consisting of rolling prairies traversed by branches of the Platte river; 576 sq. m.; pop. '90, 7092, chiefly of American birth. Co. seat, Ord.

VALLEYFIELD, t. and port of entry in Beauharnois co., Quebec, Canada; on the St. Lawrence river, the Beauharnois canal, lake St. Francis, and the Grand Trunk, the Canada Atlantic, and the Adirondack and St. Lawrence railroads; 30 miles s.w. of Montreal. It is the seat of a Roman Catholic bishop, and has a college, convent, hospital, and cotton, paper, and flour mills, electric lights, waterworks, branch banks, excellent water-power, and weekly newspaper. Pop. '91, 5515.

VALLISNE'RIA, a genus of small, stemless, aquatic plants, with grass-like leaves, belonging to the natural order *hydrocharideæ*, and found in the warm parts of both hemispheres. They generally grow in running waters. *V. spiralis* is particularly celebrated on account of its peculiar process of fecundation. At the time when this is to take place, the flowers of the female plants rise to the surface of the water by means of their long spirally-twisted stalks. The flowers of the male plants, in order to follow them thither, become detached, having previously grown on short spikes at the bottom of the water, and expand, floating about upon the surface. After fecundation, the female flowers return under the water by the spiral contraction of their stalks, and the fruit is ripened under water. This plant is found in ditches and bogs in Italy and the s. of France.

VALLOMBRO'SA, a celebrated abbey of Tuscany, situated among the Apennines, in a valley surrounded with forests of fir, beech, and chestnut-trees (hence the name, meaning "shady valley"). Here an order of monks according to the rule of St. Benedict was founded about the middle of the 11th c., who were called Vallombrosians from the name of the site, or gray monks, from the color of their habit, which, however, was afterward changed to black. They were the first to admit lay brethren. The monastery became very wealthy through donations, and the present magnificent buildings were erected in 1637. It formed a refuge for priests during French rule in Italy. After 1815, the monks resumed possession, but in very diminished numbers. In 1863 the monastery was suppressed, and the buildings were made use of for a royal academy of forestry. The monastery and its highly picturesque environs are still much visited by artists and tourists.

Vallombrosa was visited by Dante, celebrated by Ariosto in the *Orlando Furioso*, canto xxii,, and is mentioned by Milton in the *Paradise Lost.*

VALLS, an old-fashioned t. of Spain, in the province of Tarragona, on a hill in the midst of a fertile district watered by the Francoli, 55 m. w. of Barcelona. Valls is surrounded by ancient walls, has manufactures of cotton, linen, brandy, paper, and leather. The French, under St. Cyr, defeated the Spanish here in 1809; but were in their turn defeated in 1811. Pop. '87, 13,274.

VALMORE, MARCELINE FÉLICITÉ JOSÈPHE DESBORDES; 1786–1859; b. Douai, daughter of M. Desbordes, a poor artist; was educated in Guadaloupe; appeared on the stage in France as a singer, and married the actor Valmore, 1817; left the stage and gave herself to literature. Her novels are *Recueil de Poésies*, 3 vols.; *Les Veillées des Antilles*,

2 vols.; *L'atelier d'un Peintre*, 2 vols.; *Le salon de Lady Betty*, 2. vols. Her poems are *Elegies et Romances; Pleurs; Pauvres Fleurs.*

VALMY, a French village in the department of Marne, 36 m. s.e. from Rheims. In 1792, the Prussians, under the duke of Brunswick, after capturing Longwy and Verdun, were advancing toward Paris, driving the army of Dumouriez before them, when Kellermann (q.v.), who commanded the army of the Rhine, learning the critical situation of his comrade, hastened to his relief with 22,000 men, and taking up his position on the heights of Valmy, awaited the advance of the Prussians. These, possessing themselves of the heights of La Lune, immediately opened a vigorous cannonade on the French, to which the latter effectively replied. The explosion of two ammunition wagons within the French lines having thrown them into disorder, a body of Prussians, taking advantage of the confusion, advanced to the attack; but the energetic conduct of Kellermann, and the enthusiasm infused by him into his troops, restored their steadiness, and by a sudden charge with the bayonet, the Prussians were made to retire to their former position. This battle, or skirmish, frequently alluded to as the *cannonade of Valmy*, did not cost either army more than 800 men, but though, in a military point of view, an insignificant affair, it produced moral effects of the greatest importance. It was the first triumph of the republican arms, and with characteristic impulsiveness, the French were transferred from the depths of despair to the very pinnacle of self-confidence. When Napoleon was creating his "noblesse," this great service rendered to France by Kellermann was fitly remembered by his nomination as *duc de Valmy*.

VALOIS, House of, a branch of the Capetian dynasty (q.v.) which possessed the throne of France from 1327 till 1589, originated in the person of Charles, second son of king Philippe III. (*le hardi*), who obtained in 1285 the county of Valois in appanage from his father. Previously, the county of Valois had been possessed by a cadet branch of the great house of Vermandois; but on the union of the heiress of Vermandois with count Hugh the Great, the younger son of king Henry I, and the failure of their descendants in the end of the 12th c., the Vermandois possessions, including Valois, were annexed to the French crown, till again separated in 1285, as above mentioned. But Philippe IV., the elder brother of Charles, having left three sons, who reigned in succession, and died without issue male, the succession fell, by the Salic law, to the eldest son of Charles, who accordingly ascended the throne as Philippe VI. (q.v.). The elevation of the house of Valois to the throne of France gave rise to long and bloody wars with Edward III. of England, who claimed the crown through his mother, Isabel, the daughter of Philippe IV., insisting that the Salic law only prohibited the "succession" of females, and did not deny their capacity for transmitting a claim to the crown. But if Edward III.'s argument had been sound, it would have destroyed his rival's claim without benefiting himself, for the real heirs to the throne would have then been the Navarrese royal family, who were descended from the eldest daughter of Louis X. Edward, nevertheless, assumed the title of *king of France*, an example followed by all his successors till George III., and maintained his claims by force of arms till, by the mediation of the pope, a partition of the kingdom was effected. The French crown fell, by regular succession of son to father, to John the Good (1350–64), Charles V. (1364–80), Charles VI. (1380–1422), Charles VII. (1422–61), Louis XI. (1461–83), and Charles VIII. (1483–98), under the first four of whom the contest with England was carried on with spirit, at first to the advantage of the English, but latterly of the French, who, under Charles VII., succeeded in driving the English from all their strongholds, Calais alone excepted. Charles VIII. having died without leaving male issue the crown fell to the representative of the nearest collateral male line—that is, to Louis, son of Charles, duke of Orleans, and grandson of Louis, duke of Orleans, the younger brother of Charles VI., who ascended the throne as Louis XII. (1498–1515), the first of the Valois-Orleans régime; but he also dying without male issue. the succession devolved upon the descendants of his uncle, count Jean of Angoulême, whose grandson, Francis I (1515–47), next obtained the scepter, which he transmitted to his son, Henry II. (1547–59). Henry's three sons, Francis II. (1559–60), Charles IX. (1560–74), and Henry III. (1574–89), occupied the throne in succession; but none of them leaving lawful male heirs, and all the collateral male lines proceeding from Philippe III. having become extinct, the crown passed to the house of Bourbon (q.v.), which was descended from his younger brother Robert.

The most distinguished cadet branches of the royal line of Valois were, the ducal family of Anjou, which long contested with the Aragonese royal family the possession of Naples; the last and most celebrated ducal house of Burgundy; and the illegitimate line of Dumois and Longueville, which was so productive of eminent warriors and daring politicians.

The Valois monarchs of the elder line were a succession of able rulers, who, by valor and policy, wrested France from the hands of the English, and firmly established the royal authority over their powerful, proud, and turbulent nobility; those of the younger, or *Valois-Orleans* and *Valois-Orleans-Angoulême* lines were, with the single exception of Francis I., a series of weak princes, under whose feeble rule the country was distracted by contests for power between rival nobles, and religious dissensions among the people at large, though, owing to the number of able men on whom devolved the cares of

government, the country suffered less from the incapacity of its monarchs than might have been expected.

VALO'NIA, an article very extensively used by tanners, in consequence of the quantity of tannic acid which it contains. It is the acorn-cup of a species of oak (*quercus ægilops*), indigenous to Asiatic Turkey.

VALPARAI'SO, a province of Chili, bounded e. and s. by Santiago, w. by the Pacific ocean; area, 1637 sq. m.: pop. '94, (est.) 230,990. Surface mountainous, soil in the valleys fertile, producing good crops of cereals, grasses, and fruits. Agriculture is the principal industry. Wine and brandy are made. Mines of silver and copper are worked. The province is divided into the departments of Valparaiso, Quillota, Limache, and Casablanca. The islands of Juan Fernandez belong to this province.

VALPARAI'SO, the most important trading-town of Chili, South America, is situated in the province and on the bay of the same name, about 68 m. w.n.w. of Santiago (q.v.), with which it is connected by railway. It is chiefly built on a narrow strip of land, at the head of the bay. It contains theaters, colleges, hospitals, and a number of scientific and literary institutions; its streets, though narrow, are well paved; and its houses, almost all two stories high, are gaily painted, and furnished with balconies. The picturesque bay of Valparaiso, which is generally crowded with ships, is sheltered from all quarters except the north; and in the winter months, when northern gales prevail, the anchorage is considered dangerous. In 1822, the town was nearly destroyed by an earthquake; and on several occasions since that time, its progress has been checked by the same cause: in spite of this, however, Valparaiso has made great progress within recent years, its population having increased from under 10,000 in 1825, to 150,000 in 1890. Fifteen forts, mostly new, defend the bay. The imports in 1894 were 34,220,651 pesos, being chiefly cotton, silk, and woolen goods, hardware, iron, sugar, wines, spirits, tobacco, etc.; and the exports were 8,361,140 pesos, being chiefly copper and copper ore, silver, gold, wheat, flour, tallow, hides, and wool. Valparaiso was bombarded by the Spanish fleet Mar. 31, 1866.

VALPARAISO, city and co. seat of Porter co., Ind.; on the Chicago and Grand Trunk, the New York, Chicago, and St. Louis, and the Pennsylvania Co.'s railroads; 44 miles s.e. of Chicago. It is the seat of the Northern Indiana normal school; contains St. Paul's academy (R.C.), waterworks on the direct pressure system, electric light plant, national and state banks, and nearly a dozen churches; and has manufactories of machinery, self-winding clocks, and other articles, and several daily, weekly, and monthly periodicals. Pop. '90, 5090.

VALPY, RICHARD, D.D., 1754–1836; b. island of Jersey; educated at the college of Valognes, Normandy, 1764–69, graduated at Oxford, 1776; ordained in the church of England; settled at Bury St. Edmund's; rector of Stradishall, Suffolk, 1787; head master of the school at Reading, founded by Henry VII. He was a successful teacher, and prepared for the school Latin and Greek grammars and text-books which have been much used. His youngest son, the Rev. Frederick E. J. Valpy, who graduated at Cambridge, succeeded him in the school. He published *Etymological Dictionary of the Latin Language; Etymology of Words of the Greek Language in Alphabetical order.*

VALTELLI'NA, a valley of Lombardy, province of Sondrio, bounded n. by the Swiss canton of Grisons, n.e. by Tyrol, s. by the province of Brescia, Bergamo, and Como, w. by lake Como and the valley of Chiavenna. It is 45 m. long. It now forms the Italian province of Sondrio. It is very fertile, producing wine, grain, fruit, and cheese. This and the two valleys of Bormio and Chiavenna belonged to the dukes of Milan in the middle ages; became part of Grisons, 1512, and continued in possession of the Swiss, successfully resisting the efforts of Austria through the 30 years' war to get it; became part of the French department of Adda in 1804; came under Austria, 1814, as a part of Sondrio; and in 1859 became subject to Italy.

VALUE has been defined as the measure of the sacrifice involved in obtaining utility. Another and simpler definition is: value is the measure of utility. Both of these definitions are given by recent economists who have become dissatisfied with the distinction made by the older school of economists between value in use and value in exchange. It was formerly held that the science of economics had nothing to do with the former of these concepts, but only with value viewed as exchange power, i.e., that quality in a commodity which confers on its possessor a command over a certain portion of the stock of useful or desirable things. The truth is, the term value is used in several different senses. We may mean by it the power of the thing to satisfy a human want, as when we speak of a valuable improvement, or a valuable contribution to literature. Or we may mean the purchasing power of an article in the abstract, or again its purchasing power in commodities instead of in money. Owing to these different acceptations of the word and its frequent employment in different senses during the same course of reasoning, there has arisen great confusion in regard to its real signification. The older economists, by viewing value merely as power in exchange, appeared to simplify the conception, but in reality gave it too narrow limits. Their view appeared to disregard the subjective origin of value, and the fact that its degree depended upon the sacrifice which it is necessary to make in order to obtain the article which has this quality. In Austria, in recent years, several economists have applied themselves to the study of the pheno-

mena of value with the result of revolutionizing the economic views on the subject. In the United States, Prof. John B. Clark, in his *Philosophy of Wealth*, published in 1887, also took a decided stand against the older definitions. "Value and utility are," says he, "as inseparable as a measure and that which is measured. The conception of linear extension could be as logically separated from the conception of a geographical mile as the idea of utility from that of value."

To pass from the theoretical to the more practical side of the subject, the approximate cause of the value of an article at any time is the relation between the demand and the supply. The distinction between value and price is the distinction between a measure in general, and the number of units of measure by which the size of a specific thing may be expressed. Price is value expressed in terms of some one commodity. We may speak of the value of a pair of shoes as equivalent to the value of two bushels of wheat. The wheat price of the shoes is two bushels. But the ordinary expression of price is in terms of the medium of exchange, i.e., money. As to the value of money, it is determined in the same way as the value of any other commodity, viz. first, by the sacrifice which it is necessary to make in order to obtain it, and in a secondary way by the operation of the law of supply and demand. For a brief description of the Quantity Theory, see the article MONEY. As to the relation between the cost of production and value, it need only be said that value tends in the long run to conform to the cost of production, since the cost of production is in a sense the measure of the sacrifice which it is necessary to make in order to obtain it. Yet it is not the original cost of production which necessarily determines value, but the cost of production at the time at which the article is offered for sale. For instance, a machine which on account of improved processes can now be produced more cheaply than before, will not command a price commensurate with its original cost of production.

When the value of an article closely approximates its cost of production, it is called normal value. The reason why the cost of production tends in the long run to determine the value is the fact that competition tends to raise or to lower value whenever it is below or above the point at which the labor and capital engaged in production receives a fair remuneration. For instance, if the value of an article were so great that those engaged in its production derived an unusual profit, there would be a tendency for additional labor and capital to embark in the industry, and, by increasing the supply, lower the value to a point at which the profits reached the general level. On the other hand, if for any reason the value of an article was below the general level of profits in other lines of production, there would be a tendency for the labor and the capital to flow from the less productive into the more productive channels, and by decreasing the supply raise the value of that commodity. Thus the fact implied in the use of the term normal value is nothing but an application of the familiar principle that labor and capital seek their most productive channels. Nevertheless there are many influences which tend to widen the difference between the actual value of an article and its cost of production. In the first place the existence of plant may prevent the free flow of labor and capital in response to the higher profits afforded in some other business. A capitalist employer may prefer to go on selling temporarily at a loss rather than sacrifice his entire plant by suddenly throwing it on the market. Secondly, the existence of stock is apt to cause a divergence between the actual cost of production and the market value of the thing produced. A good illustration of this is the grain crop. The actual value of a bushel of grain at any one time is determined by the amount offered for sale and the amount which consumers are willing to take; but the amount offered for sale at any one time is not the entire stock on hand. Sellers retain a part in the hope of a future rise of price. Thus an element of speculation enters into the question. Moreover, the grain cannot be obtained in all seasons of the year, and producers are not always able to avail themselves of the high prices which scarcity may cause. Anything that thwarts the free action of competition tends to increase the difference between market and normal value. Custom may influence a consumer to pay more for an article than the price for which he could obtain it if he changed his dealer. On the other hand, a dealer may be influenced by custom to sell for a lower price, under certain circumstances, than he could really command. As the industrial system becomes more complicated, there is a greater liability for serious mistakes in production to arise. The producer and the consumer are further separated, and an over-production in certain lines of industry is likely to occur. When it does occur it is obvious that the producer may have to sell at a price which is insufficient to cover the cost of production.

It remains to say a few words on the subject of final or marginal utility. This term means the utility of an article to a purchaser who is just willing to take it at the existing price. It is obvious that in the consumption of goods, as the point of satiety is neared, the desire for the goods diminishes. For instance, a certain amount of bread may represent to a man the means of appeasing the pangs of extreme hunger, but, with each addition to the quantity in his possession, the point of indifference to further purchases is approached. The price which he is just willing to pay for a piece of bread measures to him its final or marginal utility. The price which any article commands in the market will measure this final or marginal utility to some of its purchasers. These, if the price were higher, would refuse to take the article, but there are others who would be willing to pay more rather than to do without. The net gain to the latter, that is the difference between what they are willing to pay and what they actually do

pay, is called by recent economists *consumers' rents.* In like manner, certain sellers would not produce at all if the price were lower, while others could afford to sell at the lower price. The net gain to the latter is termed *producers' rents.*

The principle that effective demand diminishes with the satisfaction of human wants has been investigated, statistically, by Dr. Engel, who, after studying the expenditure of incomes for many years, found that as the income of a family increased, the percentage expended for food diminished, the percentage expended for clothing remained about the same; that for rent, fuel, and light quite the same; while the percentage devoted to recreation, health, amusement, and the gratification of social ambitions, through education or otherwise, increased.

VAMBÉRY, ARMINIUS, traveler and philologist, was b. in Hungary in 1832. He was compelled to leave his country after the revolution of 1848, and went to Constantinople, where he devoted himself to studying Oriental languages. In 1861 to 1864 he traveled, in the disguise of a dervish, by routes unknown to Europeans, through the deserts of the Oxus to Khiva, and thence by Bokhara to Samarcand. His position precluded him from making instrumental observations for the purposes of geography, but was eminently favorable to an insight into the customs and language of the peoples visited. On this account, therefore, his *Travels and Adventures in Central Asia*, published at London in 1864, is a very valuable work. His other publications are *Wanderings and Adventures in Persia* (1867); *Sketches of Central Asia* (1868); *History of Bokhara* (1873); *Central Asia and the Anglo-Russian Question* (1874); *Origin of the Magyars* (1882); *Autobiography* (1883); *The Turkish Nation* (1885); *The Story of Hungary* (*Story of the Nations Series*, 1886), etc. For many years he was professor of Oriental languages at the university of Pesth.

VAMBRACED, in heraldry (Fr. *avant-bras*, fore-arm), a term applied to an arm clothed in armor, a dexter arm embowed vambraced proper, the gauntlet holding a sword below the hilt in bend sinister, point downward, argent, hilt and pommel or.

VAMPIRE (Ger. *vampyr*), called also by the Servians *vukodlak*, and by the Wallachians *murony*, is, according to the popular belief of the Slavonic, Romanic, and Greek population of the Lower Danube and the Thessalian peninsula, a blood-sucking ghost. In the mythology of the ancient Greeks, beings of a similar nature existed—the Lamias, beautiful phantom women who, by all sorts of voluptuous delusions, allured youths to them in order to feast on their fresh, young, and pure blood and flesh. And among the Greek Christians there is a belief that the bodies of those who have died in excommunication are kept by the devil in a kind of life; that they go forth from their graves by night and suddenly destroy other men, and also by other means procure food, and thus keep themselves in good condition. They are called Burkolakkă, or Tympanită; and the only way of escaping from their molestation is by digging up their unwashed corpses and burning them, after the removal of the excommunication. The vampire proper is the illegitimate offspring of parents themselves illegitimate, or the troubled spirit of one killed by a vampire. During the day he lies as a corpse, but turned in his grave, with a florid appearance and warm blood, open staring eyes, and skin, hair, and nails still growing. But by night, especially at full moon, he wanders about in the form of a dog, frog, toad, cat, flea, louse, bug, spider, etc., and sucks the blood from living persons by biting them in the back or neck. If a dead person is under suspicion of being a vampire his body is disinterred, and if it is found putrid it is only sprinkled with holy water by the priest; but if it is red and bloody, the devil is driven out, and on re-interring it a stake is driven through the breast, or a nail through the forehead; or it is perhaps burned.

The name vampire has been appropriated to blood-sucking bats. It was erroneously given to bats of the s.e. of Asia and Malayan archipelago, which are really frugivorous. The blood-sucking bats are all South American, and belong to the genus *phyllostoma*, or specter-bat (q.v.), and genera nearly allied to it. The true vampires (*desmodus*) resemble the specter-bats; they have a small bifid membrane on the nose, no tail, and the interfemoral membrane little developed. They have two great projecting, approximate upper incisors, and similar lancet-shaped superior canines, all of which are very sharp-pointed, and arranged to make a triple puncture like that of a leech. There are four bilobiate inferior incisors, the innermost separated by a wide interval; the lower canines are small; there are no true molars, but two false molars in the upper jaw, and three in the lower, of a peculiar form, apparently unfitted for mastication. The intestine is shorter than in any other mammal, and the whole structure seems to indicate that blood is the sole food. In some parts of South America, vampires are very numerous, and domestic animals suffer greatly from their nocturnal attacks. They seem to take advantage of an existing wound, but they can also make one. In some parts of Brazil the rearing of calves is impossible, on account of these bats, and there are districts, chiefly those in which limestone rocks prevail, with numerous caves, in which cattle cannot be profitably kept. Vampires sometimes attack men, when sleeping in the open air; but the stories of their fanning their victims with their wings, whilst they suck their blood, are fabulous.

VAN, a fortified town of Turkey in Asia, capital of a district of the same name, stands near the s.e. shore of lake Van, 145 m. s.e of Erzeroom. The principal public buildings, in addition to the citadel, are the mosques, the Armenian churches, the baths, the caravansaries, and the bazars. Van is always called among the Armenians, Schamiramakert—i.e., town of Semiramis—contains ancient ruins, and cuneal inscriptions are found in which the name Xerxes frequently occurs. In 1896 V. was the scene of severe fighting between the Armenian revolutionists and the Turks, each party accusing the other of being the

aggressor. Many lives were lost, but order was finally restored. Thousands of the Armenians sought and received protection at the foreign consulates in the city. Pop. stated at 30,000.—The *district* of VAN, a territory of Turkish Armenia, has sometimes been a separate pashalik, and sometimes a subordinate division. It has an area of 15,440 sq. m., and a pop. '85, of 376,297. It consists mainly of a lofty basin, surrounded by steep mountains, in the center of which is the lake of Van.—The LAKE OF VAN is a considerable inland sea, 80 m. long and 50 m. in extreme breadth, though the average breadth is not nearly so great, with an area of 1550 sq. m.

VANA'DIUM (symb. V, equiv. 51.2), a rare metal of little practical importance. The name was first given to a substance then believed to be an elementary metal, but which has since proved to be a compound. The discovery of the substance was ascribed by some to Del Rio in 1801, and by others to Sefström in 1830. The last-named chemist found it in a Swedish iron ore, and gave it the name of vanadium, from *Vanadis*, a cognomen of the Scandinavian goddess Freyja. Roscoe has, however, demonstrated that this substance is really a compound of oxygen with a metal, and to this new metal the symbol V is now appropriated. In the light of Roscoe's discovery, the V of the old formula becomes V_2O_2, and the oxides VO, VO_2, and VO_3, become V_2O_3, V_2O_4, and V_2O_5. In very small quantities, vanadium is present in nearly all clays, but its most abundant source is vanadiate of lead, which has been found in Mexico and Chili.

VANBRUGH, Sir JOHN, an eminent architect and dramatist of the 18th c., was the grandson of a Protestant refugee of Ghent, who settled in England during the reign of queen Elizabeth. Vanbrugh is supposed to have been born in Chester (in which city his father was a merchant), in the year 1666, and to have been sent to France for his education. His artistic studies were interrupted for some time by his entering the French army, which, however, he left after attaining the rank of capt. On returning to England he must soon have acquired reputation as an architect; for, in 1695, he was made one of the commissioners for finishing the palace of Greenwich for the purposes of an hospital. His first attempt at play-writing was *The Relapse*. It was brought out at Drury Lane with such success, and obtained such popularity, that Vanbrugh ranked ever after as one of the leading wits and dramatists of his day. About 1697 he wrote his famous comedy, *The Provoked Wife*, for Lincoln's Inn theater, where it was produced with even greater success than that which had attended *The Relapse*. He then, in partnership with Congreve, started a theater in the Haymarket, and there brought out his play, *The Confederacy*. But so ill-suited was this building for speaking in, that not even the brilliant wit and racy humor of the *The Confederacy* could command an audience, and Congreve abandoning the scheme, the theater had to be closed. In 1702 he erected for the earl of Carlisle the noble palace of castle Howard, in Yorkshire; and this led to his being employed as the architect of many mansions for the noble and the wealthy in other parts of the country. His reputation was now such that he was commissioned to erect Blenheim House, which the parliament had voted to the duke of Marlborough; but as no particular fund had been provided for meeting the expenses, and as parliament refused, when applied to, to grant any money for that purpose, the commission was more honorable than lucrative. The queen supplied from her own private purse most of the funds; but after her death this supply was of course stopped. The duke of Marlborough having also died, left a specific fund to be expended in meeting the architect's claims; but the duchess not only refused to pay Vanbrugh his salary, but dismissed him from his office; and the house was completed under some other management, but from the original designs. After a great deal of trouble, Vanbrugh managed to get nearly all the money that was due to him; but ever after was the sworn foe of the duchess of Marlborough. In 1714 he was made comptroller of royal works. Vanbrugh died at Whitehall on March 20, 1726, leaving his well-known and popular drama, *The Provoked Husband*, unfinished. His plays can hardly be said to be popular now, their licentious tone and loose morality preventing their being read to that extent to which the brilliancy of their wit, keenness of their satire, and genuine character of their humor would otherwise entitle them. They want the polish of Congreve's dramas, yet, at the same time, they are not infected with the artificiality, stiffness, and labored brilliancy which disfigures so many of Congreve's best scenes. The interest is well sustained throughout; the characters—such as they are—are real, natural, and racy; the situations striking, and the dialogue brilliant and unflagging. The best edition of them is contained in Leigh Hunt's *Comic Dramatists*, to which is also prefixed an excellent life of Vanbrugh. His architectural works are still among the first of their kind—massive, picturesque, varied in outline, and wonderfully skillful in composition, though a frequent carelessness in the management of details spoils some of his best effects.

VAN BRUNT, HENRY, b. Boston, 1832; educated at Boston Latin school and Harvard university; was distinguished as the architect of Memorial hall, and other buildings at Harvard, the library of the university of Michigan, library of Topeka, Kan., the buildings of the Episcopal theological school at Cambridge, Mass.; the medical school of Harvard univ., Stone hall, conservatory, and other buildings of Wellesley coll. Among the churches designed by him are the First church, Boston; St. Stephen's, Lynn; Grace, New Bedford; and the chapel of Forest Hills cemetery. He was also the architect of the First Nat'l bank of Portland, Me.; the Hildreth building, Lowell, Mass., etc. During the war he served as military secretary on the staff of the admiral commanding the North Atlantic squadron.

VAN BUREN, a co. in n. Arkansas, containing ledges of millstone grit, 998 sq.m.; pop. '90, 8567, chiefly of American birth, incl. colored. Co. seat, Clinton.

VAN BUREN, a co. in s.e. Iowa; 480 sq.m.; pop. '90, 16,253, chiefly of American birth, incl. colored. Co. seat, Keosaugua.

VAN BUREN, a co. in s.w. Michigan, having lake Michigan for its w. boundary; 630 sq.m.; pop. '90, 30,541, chiefly of American birth, with colored. Co. seat, Paw Paw.

VAN BUREN, a co. in e. Tennessee; 322 sq.m; pop. '90, 2863, chiefly of American birth. Co. seat, Spencer.

VAN BUREN, JOHN, 1810–66; b. N. Y.; educated at Yale college, where he graduated in 1828; and having undertaken the study of law, was admitted to practice at the bar in New York in 1830. His father, afterward president, having been appointed, but not confirmed, minister to England, in 1832, he accompanied him as an *attaché* during his brief stay in that country. Returning, he resumed practice, and in 1845 was appointed attorney-general of the state, an office which he held three years. The remainder of his life was spent in his professional business, in which he gained success and reputation. He was genial and agreeable by nature, a wit, and a *bon-vivant;* and became noted for popular oratory, particularly for after-dinner speeches. Died, 1866.

VAN BUREN, MARTIN, 1782–1862; b. N. Y.; a lawyer and politician before he had come of age. In 1812 he was in the state senate; three years later was attorney-general; and after being again state senator, was chosen U. S. senator in 1821. He was re-elected in 1827, but resigned to accept the office of governor of the state. He was elected vice-president in 1832 on the ticket with Andrew Jackson, and was elected president at the close of Jackson's eight years' administration in 1837. His administration was rendered notable by his financial views during the panic which occurred in its first year, and which eventually resulted in the passage of a law establishing the independent treasury system. The influence of the slavery question in politics became virulent at this time, and it was even proposed by a member of the South Carolina delegation in the house of representatives that that state should secede from the union. Mr. Van Buren was defeated for a second term in 1840 by the whig candidate William H. Harrison. In 1844 his name was proposed for nomination, but Mr. Polk was nominated and elected. In 1848 he accepted the nomination of the free-soil party, and his candidacy occasioned the election of Gen. Taylor. He now retired from public life; made a tour in Europe, 1853–55; and died at his birth-place, Kinderhook, Columbia co., N. Y., July 24, 1862. A posthumous work by him was published in 1867, *An Inquiry into the Origin and Course of Political Parties in the United States.*

VANCE, a co. in n. N. Car.; formed 1881; 342 sq. m.; pop. '90, 17,581. Co. seat, Henderson.

VANCE, ZEBULON BAIRD, b. N. C., 1830; spent a year at the university of N. C.; admitted to the bar, 1852; member of the legislature, 1854–58; member of congress, 1858; opposed the secession of his state, but when it was accomplished entered the confederate military service; elected governor while in the army, 1862; re-elected, 1864; elected to the U. S. senate, 1870; re-elected governor, 1876; and re-elected to the U. S. senate, 1879, 1884, and 1890. Died 1894.

VAN CORTLANDT, PHILIP, 1749–1831; b. N. Y.; was a land-surveyor at the age of nineteen; joined the patriot army as lieut.col. at the beginning of the revolutionary war; was appointed col. of 2d N. Y. regiment, 1776; served at the battle of Stillwater and against the frontier Indians, 1778; commanded a regiment of militia under Lafayette, 1780; made brig.gen. for gallantry at Yorktown; was a member of the legislature, 1788–90; of the state convention which adopted the U. S. constitution, 1788; state senator, 1791–94; member of congress, 1793–1809.

VANCOUVER, GEORGE, 1758–98; b. near London; entered the navy, 1771; midshipman with Capt. Cook in his voyages, 1772–75 and 1776–80; made first lieut., 1780, served several years in the West Indies, and returned to England, 1789. A quarrel having arisen between some Englishmen who had settled in Nootka and the Spanish officers who were making a survey of the n.w. coast of America, Vancouver was sent to demand the surrender of Nootka from the Spanish commander. Having obtained the surrender he spent the summers of 1792–94 in surveying the coast as far as Cook's inlet, and the winters in the Sandwich islands. Returning he surveyed part of the w. coast of South America from the island of Chiloe, and arrived in England Oct., 1795. The account of his expedition, which was nearly completed at the time of his death, was published in London (1798) in 3 vols. 4to.

VANCOUVER, city, U. S. military post, and co. seat of Clarke co., Wash.; on the Columbia river; 6 miles n. of Portland, Or. It was founded by the Hudson Bay company in 1828; contains fort Vancouver, the headquarters of the military department of the Columbia, St. James college (R. C.), orphan asylum, hospital, high school, public and school libraries, Masonic temple, electric light and street railroad plants, and national and state banks; and has a U. S. land office, steamboat, ferry, and railroad connections with Portland, large lumber, dairy, and fruit-growing interests, flour, saw, and planing mills, artificial stone works, and other industries. A fine view of Mt. Hood is here presented. Pop. '90, 3545.

VANCOUVER, the largest city of British Columbia, is finely situated on Burrard Inlet, which is a deep indentation into the mountainous coast, thus forming a fine harbor for the largest vessels. All this section was an unbroken wilderness, with a solitary saw-mill near the site of the present town, until 1885, when on account of the fine harbor, it was decided to make this the western terminal of the Canadian Pacific R. R. Settlement was begun at once, but the town was entirely destroyed by fire in 1886. Rebuilding began immediately, and of a much more substantial character. It was incorporated as a city in 1886, and has fine waterworks, gas and electric lights, electric street railroads, several banks, Stanley, East End, and False Creek parks, about a dozen churches, and daily, weekly, and semi-monthly periodicals. It is the judicial seat of New Westminster district. A regular line of steamers ply between Vancouver and Yokohama and Hong-Kong; also a daily line to Victoria, and regular lines to San Francisco and Sitka. Pop. '91, 13,685.

VANCOUVER ISLAND, an island in the Pacific ocean, forming a part of the province of British Columbia in the dominion of Canada. It is bounded on the w. by the Pacific, and on the e. by Queen Charlotte sound, Johnstone strait, Discovery strait, and strait of Georgia, which, taken together, form an open sea-way, separating the island from the mainland. Lat. 48° 20′ to 50° 53′ n., long. 123° to 128° west. It is 278 m. in length, from 40 to 50 m. in average breadth, and is of importance not only for its great natural resources, but also from its geographical position, which gives it, both commercially and in a military point of view, the command of the Pacific. Area, about 16,000 sq. miles. The main mass of the island is a mountain ridge, which rises in its highest peak, mount Arrowsmith, to the height of 5900 ft., and whose buttress-like walls descend for the most part abruptly to the shore. There are, however, in many coast-districts, especially on the s.e. and e. sides, undulating tracts, thickly wooded in general, but here and there containing patches of open grass-land. The outline of the island is boldly picturesque. The shores are marked by abrupt rocky cliffs and promontories, by pebbly beaches and sheltered coves, with fine harbors. The w. shores are gloomy and frowning in aspect, deeply indented by fiord-like arms of the sea, the banks of which are formed by steep rocks, rising like walls. The surface is diversified by mountain, precipice, hill, dale, and lake, and the whole country is more or less densely wooded, except where the mountain summits afford no foot-hold for plants, or where open grass-lands occur. There are no navigable rivers, and the streams, which are torrents in winter, and are nearly dry in summer, are short, and are valuable only as supplying power for grist and saw mills. Springs are numerous, and the water excellent. The climate closely resembles that of Great Britain, subject, however, to modifications traceable to the position of the island. The ocean that washes its shores is throughout the whole year of a remarkably low temperature, owing to the arctic currents that sweep down along the coast, even to the lat. of San Francisco; and westerly winds blowing over the chilled sea-water, modify the climate of the island considerably. The winter, as a rule, is open and wet; the spring is later and colder than in England, and the summer drier and hotter. The maximum temperature is about 84° Fahr., and the minimum about 22° Fahr. Only a small proportion of the surface is suited for agriculture, four-fifths being little better than barren rock. The crops generally raised are wheat, barley, oats, and peas. The green crops are turnips, mangold-wurzel, vetches, potatoes —which flourish here in unsurpassed excellence—and all sorts of vegetables. Fruit-culture is a very profitable branch of industry. Gold has been found; coal is very abundant; and copper, silver, lead, and other ores abound. The puma, the bear, and wolf still range in the forests; two kinds of deer are found; there are two kinds of grouse; and snipe and wild-fowl in great variety. Salmon abound. Extensive banks lie about 32 m. off the s.w. shore. All of them are well-stocked with fish, especially the cod, herring, haddock, whiting, halibut, and sturgeon. Among the valuable woods of the island, the white fir, or Douglas pine, one of the best woods for spars known, is at once the commonest and most important. In some instances, this tree has been known "to square" 45 in. *for* 90 *feet*. The cedars have an average diameter of 6 to 7 ft., and one has been measured 14 ft. in diameter. Ship-building has sprung up, and is an important branch of industry. The island contains an abundance of coal, and gold, silver, iron, copper, and excellent marble are found. There are several fine harbors, the most important being that at Esquimalt, where an imperial naval station has been established. The island contains the city of Victoria, which is the capital of the province and the seat of the see of the Anglican lord bishop of British Columbia. Pop. of the electoral district of Vancouver, '91, 18,229.

VAN CURLER, Arendt, born Holland; became superintendent of the region around what is now Albany as early as 1642. Under Governor Stuyvesant he began and carried out that policy of peace and justice to the Indians by which the people of New Netherlands and New York enjoyed immunity from hostilities and the friendship of the Indians south of Canada until the revolutionary war divided even friends of the same household. New York and Pennsylvania were the only two colonies of which this could be said. In 1642 Van Curler rode into the Mohawk country to rescue three French prisoners from their captors. This was the first of many successful efforts by which Europeans were saved from death by torture. In 1661 he bought the "Great Flat" of the Mohawk river from the Indians, led a band of settlers from Albany, and founded Schenectady in 1662, the first agricultural settlement in the province, in which farmers could hold land in

fee-simple, free from feudal annoyances, such as paying rent to a patroon or local official. In 1667, being invited to visit the French governor of Canada, he, while on his way to Quebec, was drowned off Split Rock in lake Champlain.

VAN'DA, a genus of plants of the natural order *orchideæ*. *V. cærulea*, one of the most beautiful of Indian orchids, is highly prized by cultivators in America, and plants are sold at prices of $15 and upward. It has panicles of azure flowers. Dr. Hooker found it on the Khasia mountains, growing in great profusion.

VANDALIA, city and co. seat of Fayette co., Ill.; on the Kaskaskia river and the Illinois Central and the Vandalia line railroads; 70 miles e. of St. Louis, Mo. It contains a high school, national and state banks, co. court-house (which was the state house when Vandalia was the capital of Illinois), electric light plant, water supply for fire department from large cisterns, and a paper mill, chair factory, machine shop, and stave factory. Pop. '90, 2144.

VAN'DALS (Lat. *Vandăli*, also *Vindili* and *Vanduli*), a famous race of European barbarians, probably of Germanic, though some consider them of Slavonic origin. Procopius, who agrees with Pliny in considering them one with the Goths, states that they originally occupied the country about the *Palus Mæotis* (sea of Azov), but it would appear that afterward they migrated to the n.w., and settled s. of the Baltic, between the rivers Vistula and Viadus (Oder). They make their first appearance, however, as a historic people in the 2d c. A.D., at which time they inhabited the north-eastern slopes of the Riesengebirge (called after them, *Vandalici montes*), and figure as the associates of the Marcomanni and Quadi in the plundering expeditions into Pannonia, and the wars with Marcus Aurelius. In the latter half of the 3d c., they are found in the Roman province of Dacia, along with Goths and Gepidæ. According to Jornandes, the Gothic king, Geberic, annihilated a large part of the nation on the banks of the Maros. The remainder were transplanted by Constantine to Pannonia, where they lived in peace for 60 years. But at the beginning of the 5th c., urged, it is said by Stilicho, they abandoned their new homes, and in company with the Suevi, Alani, and other German tribes, led by their king, Godegisil, burst into Gaul, which they miserably wasted for the space of three years. Thence they swept through the passes of the Pyrenees into Spain, which experienced a similar fate; and finally, after much quarreling and fighting with their German associates, they settled in a part of Bætica, which received from them the name of *Vandalitia* (mod. *Andalusia*). In 429, at the call of Bonifacius, governor of Africa, who, from being the most reliable bulwark which the western empire possessed, had been driven into rebellion by the false representations of Aëtius (see VALENTINIANUS III.), they crossed the strait of Gibraltar, under their leader, Genseric (q.v.), in one resistless horde (numbering 50,000 to 80,000 in all), carrying devastation and ruin from the shores of the Atlantic to the frontiers of Cyrene. They were joined by the Donatists (q.v.), a sect of African heretics, and being themselves Arians, they inflicted great cruelties upon the orthodox Christians. Meantime Boniface had discovered the treachery of his rival Aëtius, and set himself, when too late, to remedy the dreadful consequences of his too credulous resentment. He advanced with a small and hastily-levied force, but was defeated with considerable loss, and driven into Hippo (now *Bona*), which he defended for more than 14 months. During the siege St. Augustine died—Aug. 28, 430. Boniface, re-enforced by a Byzantine army under Aspar, now sallied out upon the Vandals, and a second defeat decided the fate of Africa. In 439 Genseric broke the peace which he had concluded with Valentinianus III., in 435, and conquered Carthage. A new peace was established which recognized the authority of the Vandals over n. Africa from the Atlantic to Cyrene, over the Balearic isles, Sardinia, Corsica, and part of Sicily. In 455 the Vandals invaded Italy, and plundered Rome for 14 days. The manner in which they mutilated and destroyed the works of art collected in the city, has originated the application of the term *Vandalism* to all similar barbarism. After the death of Genseric (477), his son, Hunneric, cruelly persecuted the Catholics; warred against the Moorish races in n. Africa, who were trying to recover their independence, and kept the Mediterranean in a state of alarm by his piracies. His successors, Guntamund (d. 496) and Thrasamund (d. 523), were comparatively mild and tolerant rulers; the latter was even friendly to literature But the warm climate, and the love of luxurious pleasure, now began to enervate the spirit of the Vandals; and the natives in different parts of Africa, showed unmistakably that they had ceased to fear them. Thrasamund was compelled to solicit aid from his brother-in-law, Theodoric (q.v.), who sent him a Gothic contingent to help him against the Moors of Tripoli. After his death, Hilderic, a son of Hunneric, became ruler, but he showed such strong leanings toward Catholicism (owing to his long residence in Constantinople), that his subjects grew discontented, and he was overthrown by his uncle, Gelimer, in 530. This led to the emperor Justinian sending an expedition, under Belisarius, against Gelimer in 533. When the latter heard of the arrival of the great Byzantine general, he caused Hilderic and his sons to be put to death, but was himself soon after forced to seek refuge in the wilds of Numidia. In 534 he surrendered, was carried to Constantinople in triumph, and ended his life in Asia Minor. Most of the Vandals were drafted into the imperial army, and "used up" in the wars with Persia. The few who remained in Africa rapidly disappeared among

the natives.—See the various histories of the Roman empire; also Papencordt, *Geschichte der Vandal; Herrschaft in Afrika* (Berl. 1837).

VANDAMME, Dominique Joseph, Count, 1770–1830; b. Cassel, department of Nord; enlisted at Martinique, 1788; returning to France at the beginning of the revolution, became at the age of 22 a brig.gen. in the army of the north. Having served under Jourdan in the campaign of 1795, he was transferred to the army of the Rhine, and distinguished himself in all the wars of the empire, but in the Russian expedition took no part on account of a quarrel with Jerome Bonaparte, king of Westphalia. In 1813 he was forced to surrender with 10,000 troops to the enemy; was confined for some time in Russia; returned to France, 1814; went to the United States, 1816; returned to Cassel in 1824.

VANDERBILT, Cornelius, 1794–1877; b. N. Y.; of Dutch ancestry. He received but little education, and while a boy earned a living by carrying passengers and produce in a small boat (periauger) between New York and Staten Island, where he lived. The war of 1812 gave him an opportunity of enlarging his business by supplying the government posts with provisions; and he saved sufficient money to purchase a schooner and engage in the coasting trade. In 1817 he ran a steamboat from New York to New Brunswick, N. J., in connection with the passenger traffic with Philadelphia; and under his able management a line of steamboats was the result of this enterprise, which became very profitable. About the year 1830 he was building and running steamboats on his own account, and rapidly accumulating wealth. In 1851 he founded a steamship line from New York to California by the Nicaragua route, and was president of the company engaged in this enterprise. In connection with this line he succeeded in warping the steamboat *Central America* up the San Juan river, and through the Castillo rapids, placing her in lake Nicaragua for the transportation of passengers and freight; a feat which had been deemed impossible. Mr. Vanderbilt's extended connection with steamboats and steamships gave him the *soubriquet* of the "commodore," a title which clung to him till his death. In 1853 he built the steamer *North Star*, on which he took his family for a trip to Europe. Two years later he founded an independent line of steamships to Havre, and built the *Ariel* and *Vanderbilt* for this route. In 1862 he presented the *Vanderbilt*, which cost $800,000, to the U. S. government, for use during the war; an act for which he received the thanks of congress, while a gold medal was struck in his honor and duly presented to him. Mr. Vanderbilt turned his attention to the railroad business in 1863, connecting himself with the Harlem railroad, to which he advanced large sums of money, and of which he became president. He next undertook to re-organize the Hudson River railroad; purchased St. John's Park in New York for $1,000,000, and erected there a freight depot; and by his skillful and energetic management of these two lines soon placed them on a firm financial basis. In 1868 he became president of the New York Central railroad; which, in the following year, he consolidated with the Hudson River road, and formed of these two, with their connections, the most important trunk line in the country. He eventually laid four tracks on the line of this great system, thus enabling the transportation of grain from the w. on a scale otherwise impossible. Mr. Vanderbilt grew to be considered the foremost railroad magnate in America. His wealth had accumulated to a vast extent, and was dispensed liberally. He founded, in 1873, the Vanderbilt university at Nashville, Tenn., at a cost of more than $1,000,000. He was simple and unostentatious in his manners, fond of horses, and of the game of whist; devoted to magnificent operations in the direction of increasing the possibilities of American commerce.

VANDERBILT, William Henry, b. N. J., 1821; son of Cornelius. In the latter years of commodore Vanderbilt's life he relied greatly on the knowledge and judgment of his son William, who, on the death of his father, assumed the offices of president of the N. Y. Central and Hudson River, and New York and Harlem railroads. He conducted these complicated enterprises with such success that his name grew to become one of the three or four so-called "railroad kings" of America. In Jan., 1880, Mr. Vanderbilt parted with a large block of his stock in the N. Y. Central railroad, being 250,000 shares at 120, amounting to $30,000,000; the largest cash transaction in railroad securities ever made. Mr. Vanderbilt was the president of the Canada Southern and the Lake Shore and Michigan Southern railroads. He contributed handsomely to the Vanderbilt university at Nashville, Tenn., founded by his father, and was a patron of the fine arts. He d. 1885.

VANDERBILT UNIVERSITY, an institution for higher education at Nashville, Tenn., named in honor of Cornelius Vanderbilt from whom it received an endowment of $1,000,000. It was founded in 1872 by the Methodist Episcopal element in the South and its original name was The Central University of the Methodist Episcopal church, South. In 1896 there were 656 students in attendance and 80 members of the different faculties. Chancellor, J. H. Kirkland.

VANDERBURG, a co. in s.w. Indiana, having the Ohio river for its s. boundary; 230 sq.m.; pop. '90, 59,809, chiefly of American birth, incl. colored. Co. seat, Evansville.

VAN DER GOES. See Goes.

VAN DER HOEVEN. See Hoeven.

VANDERLYN, JOHN, 1775–1852, b. New York; studied under Gilbert Stuart, and afterward in Paris by the assistance of Aaron Burr. In Italy he made many copies from the old masters, especially Correggio and Raphael. He lived in Europe, 1808–15. His "Marius seated amid the ruins of Carthage," was awarded the gold medal at the Louvre in 1808. In 1832 he began to paint a full length portrait of Washington for the hall of the house of representatives, and in 1839 the "Landing of Columbus" for the rotunda of the capitol.

VANDERVEL'DE, WILLIAM, commonly called the elder, in distinction from his son of the same name, was born in 1610 at Leyden. He was bred a sailor; and having a natural aptitude for art, he busied himself in drawings of marine subjects. These becoming known, were seen to be of great merit; and in 1666 he was chosen to sail with the fleet of the famous admiral de Ruyter, with a view to the commemoration on canvas of his exploits against the English. The sketches which he produced of several engagements which he witnessed procured him a great reputation; and in 1675 he was induced to settle in England as painter of sea-fights to Charles II., who allowed him a pension of £100 a year. On the death of Charles his services were retained at the same rate by his successor, James II. He died in London in 1693, and was buried in St. James's church-yard. His works were mostly colorless drawings, of great beauty and precision, many of which were afterward painted upon in oil by his much more famous son.

VANDERVELDE, WILLIAM, the younger, who was born at Amsterdam, in 1633. He received his education in art from his father, whom he followed to England. The designs produced by the father, the son was employed to color; and for this service, to him also a pension of £100 a year was assigned. This official and subsidiary employment was, however, the least important part of his activity, his time being mainly devoted to the series of original works which have given him assured rank as one of the greatest of marine painters. In his rendering of the ocean, in its various moods, Vandervelde has had few equals; and his works are now highly valued by the connoisseur. The best of them are to be found in England, the gallery at Bridgewater house being particularly rich in fine specimens. Vandervelde lived for the most part with his father at Greenwich; and after his death, in London, where, in 1707, he died.

VAN DYKE, HENRY JACKSON, D.D., b. Abingdon, Montgomery co., Penn., 1822. He graduated at the univ. of Penn., 1843; studied at Yale coll., and graduated at Princeton theol. sem., 1845, during which year he was ordained in Philadelphia. He had charge of a Pres. church in Bridgeton, N. J., 1845–52, and of one in Germantown, Penn., 1852–53. He was pastor of the First Pres. church, Brooklyn, 1853–91, resigning to accept a chair in Union Theological Seminary. He died in 1891. He was prominent in the movement to reunite the northern and southern church, 1870, and held important positions in the general assemblies.

VAN DYKE, HENRY JACKSON, b. Germantown, Penn., 1852; son of the Rev. Dr. Henry J.; graduated from the Brooklyn Polytechnic inst., 1869; from Princeton coll., with high honors, 1873; and from Princeton theol. sem., 1876. He went to Germany, 1877, and studied at the univ. of Berlin; was pastor of the United Cong. church, Newport, R. I., 1878–82; then became pastor of the Brick Pres. church, New York; was preacher at Harvard, 1890–92, and Lyman Beecher lecturer at Yale, 1895–96. He published numerous works; among the latest, *The People Responsible for the Character of their Rulers, Responsive Readings, The Story of the Other Wise Man* (all 1895); *The Gospel for an Age of Doubt*, Yale lectures (1896); *The Builders and other Poems* (1897), etc.

VANE, Sir HENRY, a notable English politician of the 17th c., was born in 1612. His father, also a sir Henry, was a distinguished statesman in the reigns of king James I. and Charles I., and received many proofs of the royal favor; but having taken part in the prosecution of Strafford (q.v.), he was deprived of all his offices of honor and emolument. When the parliament rose against the king, Vane remained neutral; and some time before the execution of Charles, he withdrew to his seat at Raby castle, where he died in 1654.—Sir HENRY VANE, the younger, studied at Westminster and Magdalen hall, Oxford, where he appears to have embraced, with all the inconsiderate enthusiasm of his character, those republican principles for which he afterward became so famous. His travels in France and Switzerland strongly confirmed him in his aversion to the government and discipline of the church of England, and in 1635 he sailed for New England—the refuge of disaffected spirits in those days. He was soon after chosen by the people governor of Massachusetts; but his predilections in favor of "antinomian" opinions soon robbed him of his popularity, and in 1636, or thereabout, he returned home. He now married a daughter of sir Christopher Wray of Ashby, in Lincolnshire, and entered on a political career. Through his father's interest, he was appointed treasurer of the navy, along with sir William Russell, and entered parliament for Kingston-upon-Hull, in 1640, but almost immediately joined Pym and the anti-court party, of which he became one of the most vehement and resolute leaders. When the civil war broke out, no man was more conspicuous in the military and theological politics of the time than Vane. He carried to the house of peers the articles of impeachment against archbishop Laud; he was a member of the Westminster assembly; a "great

contriver and promoter of the solemn league and covenant" (though in his heart he abhorred both it and presbytery, and only used them as a means of crushing the bishops); the chief instrument in carrying the "self-denying ordinance" (1644); and one of the commissioners at the treaties of Uxbridge (1644–45) and the isle of Wight (1648). But he did not view with satisfaction the increasing power of Cromwell and the army. He was too extravagant a parliamentarian, too much of a visionary and enthusiast to be pleased with the supremacy of the musket and saber, and for some time he withdrew altogether from public affairs. On the establishment of a commonwealth, however, in Feb. 1649, Vane was appointed one of the council of state; yet his antipathy to Cromwell and his factious, pragmatical, hair-spliting activity so much increased, that the former, who looked upon Vane as a subtle promoter of divisive courses, called him a "juggling fellow;" and was probably in deep earnest, when, at the dissolution of the commons, in April, 1653, against which Vane protested with a sort of feminine sharpness, he cried out: "The Lord deliver me from sir Harry Vane!" In 1656 Vane wrote a book, entitled *A Healing Question Propounded and Resolved*, which was so hostile to Cromwell's protectorate, that it was found necessary to imprison the author in Carisbrooke castle, isle of Wight. He was released after a detention of four months, and attempts were made by Cromwell to win him over, but Vane was inflexible in his fanaticism; and during the rule both of Cromwell and Richard, he maintained an attitude of sullen discontent. After meddling a little in the helpless intrigues that followed the abdication of Richard, he was ordered by parliament to withdraw to his house at Raby. When the restoration took place, Vane was one of the 20 persons excluded from the *Act of General Pardon and Oblivion;* and in July, 1660, he was committed to the tower. On June 2, 1662, he was arraigned and indicted of high treason before the Middlesex grand jury, found guilty (on the 6th), and on the 14th was beheaded on Tower hill. His son was knighted by king Charles, and raised to the peerage by king William as lord Barnard of Barnard castle. Vane was a subtle, restless, crotchety, unwise kind of man—a real thorn in the flesh of the great Cromwell. He was one of the fifth monarchy sect, and much given to extravagant religious musings, and to praying (with his friends) in language wholly unintelligible. He also wrote several political and theological treatises, which do not require special mention.—See *The Life and Death of Sir Henry Vane, Knight* (London, 1662); Birch's *Lives;* and Ludlow's *Memoirs.*

VANGS, ropes on either side of a gaff, for steadying, or acting as braces to, a fore-and-aft sail.

VANILLA, a genus of parasitical *orchideæ,* natives of tropical parts of America and of Asia, which spring at first from the ground, and climb with twining stems to the height of 20 or 30 ft. on trees, sending into them fibrous roots produced from nodes, from which the leaves also grow. These roots, drawing sap from the trees, sustain the plant, even after the principal root has been destroyed. The stem is four-cornered and juicy; the leaves long and fleshy. The flowers are in spikes, and are very large, fleshy, and generally fragrant. The fruit is a pod-like, fleshy capsule, opening along the side. The *vanilla* of commerce was formerly supposed to be the fruit of *V. aromatica,* a native of tropical America, but is now ascertained to be chiefly, if not wholly, the fruit of *V. planifolia,* a species indigenous to Mexico, Guiana, Brazil, Peru, etc., and cultivated also in some of the West India islands, the Mauritius, and Ceylon. The fruit is cylindrical, about a span long, and less than half an inch thick It is gathered before it is fully ripe, dried in the shade, and steeped in a fixed oil, generally that of the cashew nut. It contains within its tough pericarp a soft black pulp, in which many minute black seeds are imbedded. Vanilla appears in commerce in packets of 50 to 100 pods, wrapped up in cane-leaves and sheet-lead, or in small tin boxes. It has a strong, peculiar, agreeable odor, and a warm sweetish taste. The interior pulp is the most aromatic part. Benzoic acid is sometimes so abundant in it as to effloresce in fine needles. Vanilla is of little use in medicine, although it is a gentle stimulant and promotes digestion, and in large doses is said to be a powerful aphrodisiac; but it is much used by perfumers, and also for flavoring chocolate, pastry, sweetmeats, ices, and liquors. Balsam of Peru is sometimes used as a substitute for it, as it is expensive, and the whole quantity imported into Britain does not exceed four or five cwt. annually. It is in very general use in South America. Several kinds are distinguished in commerce. The best is that called *leg* or *lec,* which is almost of a black color, and covered with crystals of benzoic acid. Another kind, less fragrant, dryer, and of a darker color, is known as *simarona.* A still inferior kind, with much broader, brown capsules, is called *pompona,* or *bova.* When the fruit of vanilla is fully ripe, a liquid (*baume de vanille*) exudes from it which is unknown in Europe, but is valued in Peru. Vanilla has ripened its fruit in British hot-houses, but the flowers are apt to fall off without fruit being produced, unless care is taken to secure it by artificial impregnation. This is, in some measure the case even in the East Indies, and in some parts of America itself; and it is supposed that the presence of some insect, delighting in the flowers of the vanilla, makes it more productive in other parts of America, especially in Mexico.

VAN LENNEP, Henry John, d.d., b. Smyrna, 1815; sent to the United States for education at the age of 15; studied at the Mt. Pleasant institution, Amherst, Mass.: graduated, Amherst college, 1837; studied theology at Andover; sailed as a missionary

of the American board to Turkey, 1839; stationed in Constantinople, Smyrna, and Tocat in connection with educational institutions; traveled in Greece, Palestine, and Egypt; returned to the United States, 1869, and became a professor in Ingham university, Le Roy, N. Y., and principal of Sedgwick institute, Great Barrington, Mass. He d. in 1889.

VANLOO, Charles André, younger brother of Jean, was born in 1705, at Nice. As a boy, he was with his brother at Rome, and studied under Benedetto Luti. He accompanied his brother in 1719 to Paris, where, after some little interval, in which he was employed as a decorative artist at the opera-house, he betook himself to portrait painting. He returned in 1727 to Rome, and there he executed some works which laid the basis of his future reputation, procured him, through the influence of the cardinal De Polignac, a pension from the king of France, and in 1729 the title of cavaliere from the pope. On leaving Rome, he visited Turin, painted there for the king of Sardinia a series of subjects from the *Jerusalem Delivered* of Tasso, and returned to Paris in 1734. The year following he was made a member of the academy, and his subsequent career was one of full prosperity. Tempting offers were made him by Frederick the great, who desired to have him in his service; but he declined them in favor of a nephew, preferring to remain in Paris. In 1751 he was made by Louis XV. a knight of the order of St. Michael; and in the course of the same year he became director of the academy. In 1762 he was made chief painter to the king, and three years after he died. As the last really great specimens of the old French school of historical painting, his works have still their admirers.

VANLOO, Jean Baptiste, a member of a family originally Flemish, in which a love of art seemed indigenous, was born at Aix in Provence, in 1684. His grandfather and father were both painters of some talent, and under the instruction of the latter, while yet a mere boy, he is said to have attained considerable proficiency as an artist. Subsequently he settled himself as such at Nice, and afterward at Toulon, where he married the daughter of an advocate. On quitting Toulon, on the occasion of its being besieged by the duke of Savoy in 1707, he returned to his native place, and abode some years there. He was again at Nice in 1712, and in the year following he visited Genoa and Turin. At the latter of these cities he won the favorable regard of the prince of Corignano, son-in-law of the duke of Savoy, and was sent by him to study at Rome as a pupil of Benedetto Luti. After a further residence at Turin, he proceeded in 1719 to Paris, where apartments were assigned him in the hôtel of the prince his patron. Here he speedily acquired a great reputation as a portrait-painter. He was made a member of the academy in 1731, and professor of painting in 1735. The loss of a large sum of money in the Mississippi scheme induced him to come, in 1738, to London, where his portraits soon distanced all rivalry. His health, however, having given way, he retired in 1742 to his native district, Provence, where he died 1745.

VAN MARCKE, Émile, b. Sèvres, France, in 1827; studied art under Troyon; was celebrated chiefly as a painter of cattle; was a chevalier of the Legion of honor; exhibited several pictures at the Paris salon. Among his best known works are, "The Village Pasture, Normandy," 1875; "A Herd of French Cattle," "Landscape with Cattle," 1876, and "The Spring at Neslette, in Normandy," 1877. He d. 1890.

VANNES, a seaport town of France, capital of the department of Morbihan, stands at the mouth of the Vannes, which falls into a narrow inlet of the gulf of Morbihan, 310 m. w.s.w. of Paris by railway. The town is surrounded by high walls flanked with towers. The cathedral and the museum are the most important edifices. Pop. '91, 19,625.

VANNUCCI PIETRO. See Perugino.

VAN OOSTERZEE, Jan Jacob, b. Holland, 1817; educated at Utrecht, and became a minister of the Reformed church. He was a minister of the most important church in Rotterdam, and gained a high reputation as a pulpit orator, 1844–62, when he was appointed professor of systematic and practical theology at Utrecht. Among his works are *The Life of Jesus; Theology of the New Testament,* and *Christian Dogmatics.* D. 1882.

VAN RENSSELAER, Cortlandt, d.d., 1808–60; b. N. Y.; graduated Yale college 1827; admitted to the bar, 1830; studied theology at Princeton seminary; ordained, 1835; preached in Virginia; pastor of First Presbyterian church, Burlington, N. J., 1837; corresponding secretary of the board of education of the Presbyterian church, whose affairs he conducted with great efficiency; agent for Princeton college, for which he raised $100,000. He contributed largely to the *Presbyterian Magazine,* which he had founded; and published addresses, sermons, and essays. A posthumous volume of *Essays and Discourses, Historical and Practical,* was edited by his son.

VAN RENSSELAER, Henry Killian, 1744–1816; b. N. Y.; col. of a N. Y. regiment in the revolution. In 1777 he repelled an assault by the British near fort Ames, but retired on the evacuation of Ticonderoga by Gen. St. Clair. He participated in the operations about Saratoga, and was dangerously wounded. A mutiny in his regiment, caused by the disputes between New York and New Hampshire, was suppressed by Washington.

VAN RENSSELAER, Stephen, known as "the Patroon," an American statesman, and patron of learning, was b. N. Y., Nov. 1, 1769, the fifth in descent from Kiliaen Van Rensselaer, the original patroon or proprietor of the Dutch colony of Rensselaerwyck,

who in 1630, and subsequently, purchased a tract of land near Albany, 48 m. long by 24 wide, extending over three counties. He was educated at Princeton and Harvard colleges, and married a daughter of Gen. Philip Schuyler, a distinguished officer of the revolution. Engaging early in politics, at a period when they were the pursuit of men of the highest social position, he was, in 1789, elected to the state legislature; and in 1795, to the state senate, and became lieutenant-governor, president of a state convention, and canal commissioner. Turning his attention to military affairs, he was, at the beginning of the war of 1812, in command of the state militia, and led the assault of Queenstown; but the refusal of a portion of his troops, from constitutional scruples, to cross the Niagara river, enabled the British to repulse the attack, and the gen. resigned in disgust. As president of the board of canal commissioners for 15 years, he promoted the New York system of internal improvements; as chancellor of the state university, he presided over educational reforms; and as president of the agricultural board, aided to develop the resources of the state. At his own cost he employed Professors Eaton and Hitchcock to make agricultural surveys, not only of his own vast estates, but of a large part of New York and New England, the results of which he published in 1824; he also paid Prof. Eaton to give popular lectures on geology through the state. In 1824 he established at Troy an institution for the education of teachers, with free pupils from every county. Widening the sphere of his political interests, he went to congress in 1823, and served several terms, exerting a powerful influence, and securing the election of John Quincy Adams as president of the United States. After an active, useful, and honorable career, worthy of his high position, he died at Albany, Jan. 26, 1839.

VAN SCHAICK, Gozen, 1737–87; b. Albany, N. Y.: was in the expedition against Crown Point in 1756, and in the French, Indian, and revolutionary wars. In the latter he was sent to Cherry Valley to protect that settlement from the depredations of the British and Indians. He was engaged in the battle of Monmouth, and for his services in the war with the Onondaga Indians received the thanks of congress; brevetted maj.gen. 1783.

VAN VEEN, Otho (called also Ottovenius), an eminent painter, was a native of Leyden, of which city his father was a wealthy burgomaster. The exact year of his birth is involved in some obscurity; but there seems tolerable evidence to fix it as about 1556–57. He received a careful education, and in aid of the natural talent he displayed for drawing, the best masters were procured him. When about 15 years old he was sent to Liége, whence, after a residence of three years, he proceeded to Rome, where he became a pupil of the celebrated Zucchero. In Italy he remained about eight years; and on his return home by way of Vienna, the emperor, by tempting offers, vainly endeavored to detain him in his service. It is significant of the estimation in which he had come to be held as an artist, that on his passing through Munich and Cologne, similar offers were pressed upon him. These also, however, he declined, wishing to settle in his native country. Finally, he went to reside at Brussels, as painter to the famous Alexander Farnese, duke of Parma, and then governor of the Spanish Netherlands, of whom he executed a masterly portrait in armor, which greatly increased his reputation. The duke having died, he established himself at Antwerp, and opened an academy, at which the great Rubens was one of his pupils. In the matured art of Rubens, traces of his master are still, it is thought, to be detected; and in particular, he is held to have in all probability derived from him that fondness for allegorical and emblematic subjects which possessed him not always to his advantage. On the occasion of the entry into Antwerp of the new governor, the archduke Albert of Austria, Van Veen was employed to design the arches and the other decorative business of the ceremonial, and so pleased was the duke with the taste and invention displayed, that he appointed him master of the mint at Brussels, to which city he returned to reside. An invitation to Paris was subsequently sent him by Louis XIII., but this he saw fit to decline; and in Brussels, at the age of 78, he died.

The chief works of Van Veen are religious pictures for churches. In the cathedrals of Leyden, Antwerp, and Bruges, good specimens may be found. On their own account they deserve attention; but it is chiefly as "the work of a man who had the honor to be the master of Rubens" (to quote the words of Reynolds), that they now are esteemed.

VAN WERT, a co. in w. Ohio, bounded on the e. by the Miami and Erie canal; 405 sq.m., pop. '90, 29,671, chiefly of American birth. Co. seat, Van Wert.

VAN WERT, village and co. seat of Van Wert co., O.; on the Cincinnati, Jackson, and Mackinaw and the Pennsylvania Co.'s railroads; 30 miles s.e. of Fort-Wayne, Ind. It contains public and high school libraries, three public parks, electric light plant, waterworks supplied from wells, national banks, about a dozen churches, railroad machine shops, and piano, sucker rod, stave, and handle factories. The village was incorporated about 1868, is in an agricultural region, and has daily and weekly newspapers. Pop. '90, 5512.

VAN ZANDT, a co. n.e. Texas, bounded on the n.e. by the Sabine river; 840 sq. m. pop. '90, 16,225, chiefly of American birth, with colored. Co. seat, Canton.

VAPEREAU, Louis Gustave, b. France, 1819; educated at the Orleans college and the Paris normal school. He lectured on philosophy at the college of Tours for ten years; studied law, and became advocate in 1854. The first edition of his *Dictionnarie*

des Contemporains appeared in 1858; several editions of which have since been published. He has also published a *Dictionnaire Universel des Littérateurs*, and edited the annual *L'Année Littéraire et Dramatique* and other kindred works.

VA'POR. As all *solids*, with the exception of carbon (an exception most probably due to our not being able to produce a sufficiently high temperature), are melted, or rendered *liquid* by the application of heat (q.v.), so a further application of heat converts them into *vapor*. A vapor is really a gas, but it requires a little consideration to convince ourselves of the fact. Perhaps the best proof that can be given is that supplied by the beautiful experiments of Faraday (q.v.) and others on the liquefaction of gases. Hydrogen, oxygen, and nitrogen were long exceptions; but now all gases have been liquefied by a proper application of pressure or cold, or of cold and pressure combined. The difference, in common language only, between a vapor and a gas is this: A gas is a substance which at ordinary temperatures and pressures exists in a state of vapor; while a vapor is produced by the application of heat to a substance which is ordinarily found in the solid or liquid form. In other words, gases are the vapors of substances which, in the liquid form, boil at very low temperatures.

The most familiar instance of vapor is aqueous vapor, or steam (q.v.). At all temperatures, even as low as the freezing-point, ice and water give off vapor; and the quantity produced is determined by the temperature alone; that is, evaporation (q.v.) at any temperature continues (more or less slowly according to the quantity of air or other gas which is present) until the pressure exerted by the vapor upon the containing vessel attains a certain definite value, depending on the temperature alone. If the temperature be such that the corresponding vapor-pressure is equal to the pressure of the air, vapor comes off freely, and we have the phenomenon called boiling.

Vapor in a vessel which contains some unevaporated water is thus always *saturated*, as it is called, i.e., the full amount of vapor capable of existing at the temperature of the vessel is present. If it be compressed, some is liquefied; if allowed to expand, more vapor is formed.

If, however, there be no water present in the liquid form, and the temperature be gradually raised, the pressure of the vapor will rise, but much more slowly than when water is present, because no more vapor can be formed. In this state—that of *superheated* steam—vapor behaves almost exactly as an ordinary gas.

Chlorine, carbonic acid, sulphurous acid, etc., thus exist at ordinary temperatures as *superheated* vapors; and can therefore be reduced by cold and pressure to the condition of *saturated* vapor, when they are easily liquefied by carrying the process further.

Aqueous vapor may be liquefied by cold alone, or by pressure alone, as we have seen; and at ordinary temperatures it is easy to liquefy sulphurous acid, ammonia, and even carbonic acid and laughing gas, by mere compression. Gases absorbed by charcoal, or by spongy platinum, i.e., condensed by intense molecular forces on the large surface presented by the interstices in these bodies, must in all probability exist in the state of liquids. Carbonic acid is liquefied when exposed to a pressure of 35 atmospheres at ordinary temperatures; and some varieties of charcoal absorb from 80 to 100 times their bulk of this gas. Remembering that, on account of the impenetrability of matter, the gas can only be in the *pores* of the charcoal, and that their whole bulk forms but a small fraction of that of the charcoal itself, we see that in all probability the absorbed gas must be condensed so enormously as to have become liquid. It is probable that in Graham's recent process, for separating by dialysis (see OSMOSE) the oxygen and nitrogen of the atmosphere, the film of vulcanized india-rubber which is employed as septum compels these gases to pass through its pores in a liquid form.

Some extraordinary experiments, due to Cagniard de la Tour (the inventor of the Sirène, q.v.), have given us valuable information on the subject of vapors. He showed that when water, ether, and other liquids are hermetically sealed in glass tubes, so as to fill from a quarter to a half of the tube, the application of the requisite amount of heat is sufficient to convert the whole into vapor. This vapor, therefore, has a density equal to half or quarter of that of the liquid! Ordinary steam from boiling water has only about $\frac{1}{1700}$ of the density of water (in common language, a cubic inch of water gives a cubic foot of steam). These experiments are very dangerous.

Some important experiments of this nature are due to Andrews. Having, by mere pressure, partially liquefied carbonic acid in a glass tube, he raised the temperature gradually, and observed that the demarkation between the liquid and the gas became less and less definite; the capillary curvature of the surface of the liquid also diminishing. At about 88° Fahr., the liquid surface became horizontal, and the liquid disappeared. The tube then appeared to be filled with a homogenous substance, neither gaseous nor liquid; apparently a new state of matter. When the temperature was slightly diminished, or the pressure relaxed, there was a singular appearance of flickering striæ, such as one sees on mixing alcohol and water, or on looking through the column of irregularly heated air rising from a hot body. No pressure that Andrews could apply, not even 400 atmospheres, could liquefy this gas when its temperature was above 88° Fahr. It appears that for every gas there is a point of temperature above which it is impossible by any amount of pressure to liquefy it.

The so-called permanent gases—oxygen, hydrogen, and nitrogen—have at last yielded

to the patience and skill of M. Pictet of Geneva and M. Cailletet of Paris, and have been liquefied, or even solidified. In the last months of 1877 oxygen was liquefied under a pressure of 500 atmospheres; hydrogen, when subjected to a pressure of 280 atmospheres; and nitrogen, under a pressure of 200 atmospheres.

VAR, a department in the extreme s.e. of France, bounded on the s. and s.e. by the Mediterranean, and on the n.e. by the department of Alpes Maritimes. See Alpes Maritimes. Area, 2349 sq.m.; pop. '96, 309,191. The department receives its name from the river Var, which formerly served as its boundary on the e., but which, since the arrondissement of Grasse was taken from the department of Var, and added to that of the Alpes Maritimes, now belongs entirely to the latter. Var is well watered by a great number of streams, of which the chief are the Gapau, Argens, and Bianson. In the n. and n.e. it is mountainous, being traversed by a branch of the *Alpes de Provence*, called the Monts de l'Esterel. Between the mountains and the water-courses are many very fertile valleys. The climate of Var, tempered by the altitude of the surface, is pleasant. Fruits of all kinds are here cultivated with remarkable success; tobacco is grown, and the department abounds in minerals; an active commerce is carried on, the exports being chiefly wine, fruits, olive-oil, and other agricultural and horticultural products. It is divided into the three arrondissements of Draguignan, Brignoles, and Toulon. Capital, Draguignan.

VARANGIANS (Ger. *Waräger*, or *Väringer*), a Norman people of the Baltic coast, who greatly damaged by their piracies the commerce of the republic of Novgorod, and subjugated repeatedly the Slävic and Finnish peoples of northern and central Russia. They forced the Krivitches, Tschudes, and other tribes to pay tribute, and wrested from the Russians the districts now known as Revel, Petersburg, and Archangel; the Russians retreating into Finland and Karelia. Gradually the two nations became intermixed, and toward the 9th c., the names Russian and Varangian appear to have been considered synonymous. In 862, the rulers of this Russo-Varangian nation, Rurik (q.v.), Sineous, and Truvor, were invited by the federative state of Novgorod, in which the Släves were dominant, to put themselves at its head, and Rurik accepting the invitation, founded the Russian monarchy. See Russia. The Varangians were at first distinguishable in various ways above the other peoples of the Novgorod state; but being far inferior in number, were soon forced to adopt the Slävic tongue, conform to Slävic manners, and so become merged in the predominant population. The great success which attended this experiment of the Novgorod confederacy, induced other Slävic states which were located on the Dnieper to put themselves under the protection of the warlike Varangians; and accordingly we find, soon after 862, a second Slävic state at Kiev, under the rule of Oskold, a Varangian chief, and the conqueror of the barbarous Chazars. After Rurik's death, his successor in power, the Regent Oleg, united Kiev to Novgorod, making Kiev the capital—a position it held till supplanted by Moscow (q.v.).

VARAN´IDÆ, a family of saurian reptiles, having a very elongated body, without a dorsal crest; strong legs, and long unequal toes; the tail long and slightly compressed; the scales tuberculous, and arranged in rings; the tongue protractile, dividing into two points as in serpents. Some of them are aquatic, and some inhabit dry and sandy places. The terrestrial species have the tail conical; the aquatic species have it compressed and often crested, so that it becomes a powerful organ of locomotion in water. The motion of the terrestrial species is aided by the tail, and is always serpentine. Some of the varanidæ attain a large size. They feed on animal food of any kind, and have been seen to attack a young deer swimming across a river. The species are not numerous, and belong chiefly to the eastern hemisphere.

VARAZ´ZÉ, a small t. of northern Italy, in the province, and 18 m. s.w. of the city of Genoa. Some trade in wood and extensive construction of fishing-boats are here carried on. Pop. '81, 8237.

VARDÖE, an island in the Arctic ocean, off Finland, lat. 70° 20′ n., long. 31° 10′ east. It belongs to Norway. Its fortified town, Vardöehuus, is the most northerly town in Europe.

VA´REC, an old name for crude carbonate of soda.

VARE´SE, a t. of northern Italy, in the province of Como, and 13 m. w. of the town of that name. It is a handsome town; contains a number of fine palaces and magnificent villas; and carries on manufactures of silk, cotton, paper, and hats. Pop. '81, commune, 13,966. Varese is of very ancient origin. The Romans kept it strongly garrisoned as a stronghold against invasion from the north.

VARGAS, Luis de, 1502–68; b. Seville, Spain; studied art in Italy and for many years resided in Rome. On his return to Seville he painted many frescos, altar pieces, etc., for the churches. Of these the best, still preserved in his native city, are "La Generacion," "Jesus bearing the Cross," and "Adam and Eve." His portrait of the duchess of Alcalá is one of the finest works of art of the century.

VARIATION, in music, a transformation of a melody by melodic, harmonic, contrapuntal, and rhythmic changes. The subject chosen is called the theme; it is first simply harmonized with or without an introduction, and then repeated in a variety of different

transformations and the variations collectively with the theme constitute the piece Occasionally the different variations are combined by an intermediate passage; but generally each has its separate close, and the whole terminates with an extended and richly-developed variation, or a coda.

VARIATION OF THE COMPASS. See TERRESTRIAL MAGNETISM.

VARICEL'LA (Lat. a little pimple), popularly known as chicken-pox (q.v.).

VARICK, RICHARD, 1753–1831; b. Hackensack, N. J.; practiced law in New York city before the revolutionary war, and entering the army commanded a company, became military sec. to Gen. Schuyler commanding the northern army, and filled other responsible offices until the capture of Burgoyne 1777. In that year he was appointed inspector gen. at West Point, holding the post until Arnold's treason was exposed; then became recording sec. at Washington's headquarters, with the rank of col. He was recorder of the city of New York, 1783–89; atty. gen. of the state, 1789, afterward mayor of the city. Associated with Samuel Jones, he revised the state laws in 1786. He was one of the founders of the American Bible society, and its president, succeeding John Jay.

VARICOCELE' (known also as CIRCOCELE) is a term used in surgery to designate a varicose state of the veins of the spermatic cord. It is caused by the same conditions which give rise to varicose veins (q.v.) elsewhere—viz., weakness of structure, combined with obstruction through corpulence, constipation, etc., to the return of the venous blood. For a description of its symptoms, and of the suitable treatment, we must refer to any ordinary text-book of surgery.

VARICOSE VEINS. When a vein becomes dilated at a certain part of its course, for no apparent physiological object, such as relieving the venous circulation elsewhere (as, for example, in the case of the superficial abdominal veins enlarging in order to relieve a compressed vena cava), it is said to be varicose, the actual dilatation being called a *varix* (a word used in this sense by Cicero and Celsus). Some veins seem to be unaffected by varices, which, however, are of common occurrence in the sub-mucous veins of the rectum (constituting hemorrhoids or piles), in the spermatic veins, giving rise to varicocele (q.v.), and in the veins of the lower extremities. They are occasionally (but very rarely) found in other veins. Certain conditions of the system favor the formation of varices, among which may be noticed an indolent temperament, and a debilitated condition of the general system, accompanied by a relaxed state of the walls of the veins; and possibly also a congenital predisposition or hereditary tendency. Persons with such a predisposition are more likely to suffer from this affection if their occupation is one which involves much standing or walking; and cooks, washer-women, and foot-soldiers have been selected as specially prone to varicose veins. Varices may occur at almost any period of life, but are chiefly developed during middle age. Their formation is aided by any condition of the system which impedes the circulation, as certain diseases of the heart, lungs, and liver; and by continued *high living*, which is especially liable to induce hemorrhoids. From the researches of Andral, it appears that in varicose veins the coats of the dilated vessels may become thickened or may become thin; that they may be lengthened so that the veins become tortuous; and that the dilatation may be unequal, giving rise to the formation of pouches; and that, in consequence of the enlarged caliber of the vessels, the veins only act imperfectly, and gradually undergo degeneration. Varices occurring in the leg, to which our remaining observations apply, commonly give rise to deep-seated aching pain in the limb, with a sense of weight, fullness, and numbness, before there is any external appearance of the affection. In a more advanced stage, the ankles swell in the evening, and the feet are always cold. After a time, a small tumor of a bluish tint appears, which disappears on pressure, but returns on the removal of the pressure, and is caused by a dilating vein. This dilatation extends, and forms knotty, irregular tumors, soft to touch, diminishing on pressure, or on the patient's assuming a horizontal posture, and giving a bluish tint to the adjacent skin. These tumors commonly occur in the middle of the leg, along the track of the saphena veins, but they often extend along the whole of the leg and thigh. With regard to treatment, it may be mentioned that old varices cannot be cured, except by operations dangerous to life, although much may be done for their relief. In their earlier stages, they are, however, more amenable to treatment. As the disease is a very common one, we shall enter somewhat in detail into the palliative treatment which any one may adopt for himself. The venous circulation of the limb should be as much as possible facilitated by the disuse of garters; by keeping the limb (if the means and condition of the patient permit it) in a horizontal position for a month or six weeks; by prohibiting walking, and allowing only carriage-exercise, with the leg elevated to the horizontal position The limb should also be carefully bandaged from the toes to above the knee, the bandage being replaced daily, and the limb then well rubbed with the hand, or with a flesh-brush, for ten minutes or more, from below upward, so as to stimulate the circulation. When the circumstances of the patient hinder this treatment, elastic stockings may be tried during the day, or ordinary bandages, with a pad of lint placed on each varicose cluster before the bandage is applied. In cases where only one or two trunks are affected, the disease may be prevented from extending by the application of pieces of wash-leather spread with soap-plaster firmly over them. At the same time, the general

health must be attended to. Ill-nourished, feeble patients must be treated by tonics and nourishing diet; while over-fed, plethoric patients require mild but often repeated purgatives to relieve the portal circulation. In the numerous cases in which there is a relaxed condition of the veins, the tincture of sesquichloride of iron may usually be given with advantage in half-dram doses thrice daily in half a tumbler of water, with a colocynth pill every second night, to obviate the constipating action of the iron. Among the means of effecting a *radical cure*, by causing coagulation of the blood in the dilated veins, when they shrink and contract permanently, are (1) caustic potash applied over the course of the vessel, (2) subcutaneous incision of its walls, and (3) compression of the vessel between a steel pin and a twisted suture. We believe that the cases are rare in which the pain of the varix is so great as to disqualify a patient from his ordinary work, and these are the only ones in which any of these operations should be recommended; "and the patient," says Mr. Callender, "if wise, will be contented with the palliative measures of a more simple character."—Holmes's *System of Surgery*, vol. iii., p. 321. Among the troublesome consequences of varicose veins are the obstinate ulcers, known as varicose ulcers, to which they give rise; and it must be borne in mind that occasionally, when the skin gets thinned by prolonged pressure, the varices burst through it, and give rise to hemorrhage, which, if not promptly stopped, may cause fainting, and even death. When such an accident occurs, the patient should at once be placed in a horizontal position, and the leg raised, in which case the bleeding will probably cease. If it continue, a pad of lint must be pressed upon the mouth of the bleeding vessel by means of a few turns of a bandage round the limb.

VARIETY, in natural history, a term employed to designate groups subordinate to species (q.v.). Varieties are regarded as less permanent than species; and those who regard species as perfectly distinct in their origin, look upon varieties as modifications of them due to particular causes. Of course those who adopt Darwin's view of species do not deem the distinction between species and varieties so important, but rather consider varieties as species in process of formation. However this may be, all naturalists acknowledge a difficulty of deciding what are varieties and what are species; and some reckon as varieties what others regard as distinct species. The whole subject is involved in difficulty, and must be studied both with respect to general principles, and to the peculiarities of particular cases. Whatever theory may be adopted, many of the groups now distinguished by particular names are doubtful, and their designations must be regarded as merely provisional. It cannot be certainly said whether they are varieties or species. The term *variation* has been employed by some authors to designate forms less permanent than varieties, but the term has not obtained general acceptance.

VARI'NAS, or BARINAS, a t. of Venezuela, in the province of Zamora, near the San Domingo. It stands at the entrance to a valley covered with tobacco-plantations. Varinas carries on a trade in tropical productions and in cattle. Pop. stated at 4000.

VARI'OLA. See SMALL-POX.

VA'RIX. See VARICOSE VEINS.

VARNA, an important seaport of the principality of Bulgaria, on the northern side of a semicircular bay, an inlet of the Black sea, 189 m. n.n.w. of Constantinople. The congress of Berlin in 1878 decided that the strong fortifications by which the port was formerly defended should be destroyed. Varna stands on a sandbank, and the city wall, the base of which in some places is 20 or 30 ft. above sea-level, is in other places on a level with high-water. It is the ancient *Odessus*. The town itself is crooked, irregular, dirty, and dilapidated, and as viewed from the sea, it presents a huge jumble of red-tiled houses, interspersed here and there with mosques and minarets. There are a number of distilleries, breweries, tanneries, and soap factories. Pop. '93, 28,174. The allied French and British troops were here encamped for some time in 1854.

VARN'HAGEN VON ENSE, KARL AUGUST LUDWIG PHILIPP, 1785–1858; b. Düsseldorf; studied medicine at the university of Berlin, and in 1804, in conjunction with Chamisso, published a *Musen-almanach*. He then studied philosophy at Halle, Berlin, and Tübingen. In 1809 he received a commission in the Austrian army, and was wounded at the battle of Wagram. In 1813 he accepted a commission as capt. in the Russian army, and accompanied Tettenborn as adjt. on his march to Paris. He then entered the Prussian diplomatic service, and accompanied prince Hardenburg to the congress of Vienna in 1814. After the war of 1815 he was appointed resident minister at Karlsruhe, where he remained till 1819, when he retired from public affairs, and devoted himself to literature at Berlin. He published *Deutsche Erzählungen* (1815); *Vermischte Gedichte* (1816); *Göthe in der Zeugnissen der Mitlebenden* (1823); *Biographische Denkmale* (5 vols. 1824–30); and *Denkwürdigkeiten und vermischte Schriften* (7 vols. 1843–46) and other works.

VARNISH is a solution of some resinous material in any proper solvent, alcohol and oils being the ones chiefly employed. The solution must be of such consistency as to enable it to be very thinly and smoothly spread over the surface intended to be var-

nished, so that when it dries, it leaves a thin resinous coating, which is either naturally glossy, or can be made so by mechanical polishing. From the extremely inflammable nature of the material employed, the preparation of varnish is extremely dangerous, and should not be attempted except in premises specially adapted for the purpose, and with skilled workmen. The resinous gums, such as copal, anime, and mastic, and the various kinds of lac, are those chiefly used; the copals and anime are employed in making the oil-varnishes, and the lacs and gum-mastic for spirit-varnishes. Heat is required with both kinds of solvents, and it is obtained by hot-water baths as a means of safety. Coloring matters are added to some varnishes, especially to those used on metal, as the lacquer varnish used to protect the polished surface of brass, which is colored with gamboge and turmeric. Saffron, aloes, dragon's-blood, and asphalt are also used to give yellow, brown, red, and black colors.

VARNISH TREE, a name given to several trees of the family *anacardiaceæ*, the resinous juice of which is used for varnishing or for lacquering. The BLACK VARNISH TREE (*melanorrhœa usitata*) is described in the article MELANORRHŒA; the JAPAN VARNISH TREE (*rhus vernicifera*) in the article SUMACH. Another tree, valuable for the varnish which it yields, is *stagmaria verniciflua*, a native of Java, Sumatra, Borneo, Celebes, and other East India islands. The juice is extremely acrid, and soon hardens into a black resin. To obtain it pieces of bamboo are inserted into the bark, and allowed to remain all night, as the juice flows more freely by night than by day. It sells at a high price. It is prepared for use by boiling it with equal parts of oil, obtained from the fruit of the *mimusops elengi*. The exhalations of the tree are said to be very noxious.

VARNUM, JAMES MITCHELL, 1748–89; b. Mass.; educated at Brown university and admitted to the bar. He entered the continental army in 1774 at the head of a Rhode Island regiment, and became a brig.gen. in 1777. The same year he had command of the American troops on the New Jersey side of the Delaware. He was at Valley Forge and at the battle of Monmouth, and he took part in the campaign in Rhode Island. He resigned in 1779. He was a member of congress, 1780–82 and 1786–87. He was appointed a justice of the supreme court of the North-west territory in 1788.

VARRO, "the most learned of the Romans," so called from his vast erudition in almost every department of literature, was b. 116 B.C., and educated first under L. Ælius Stilo Præconinus, and then under Antiochus, a philosopher of the academy. Varro served with distinction in the wars against the Mediterranean pirates and Mithridates; but afterward as legatus of Pompey in Spain, he was compelled to surrender his forces to Cæsar. He continued to share the fortunes of the Pompeian party till its defeat at Pharsalia, after which he solicited and obtained his pardon from Cæsar, by whom he was employed to collect and arrange the great library designed for the public. The next period in Varro's life was spent in literary retirement, chiefly at his villas near Cumæ and Tusculum. When the 2d triumvirate was formed, his name was enrolled in the list of the proscribed; but he succeeded in escaping, and, after some time spent in concealment, he was received under the protection of Octavian. The residue of his long life was spent in the tranquil prosecution of his favorite studies, rendered all the more arduous by the destruction of his magnificent library. He died in his 89th year, 28 B.C. Varro was not only the most learned, but also the most prolific of Roman authors. He himself confesses to having composed no fewer than 490 books; but only two of these have survived, and one of them in a fragmentary state. The most considerable of his writings, whether lost or extant, are as follows: 1. *De Re Rusticâ, Libri III.*, still extant, and though written in the author's 81st year, constituting the most important treatise on ancient agriculture known to us. 2. *De Linguâ Latinâ*, a grammatical work, which originally extended to 24 books, only 6 of which, however, have come down to us, and even these in an imperfect form. But for this treatise, mutilated as it is, we should be ignorant of many terms and forms, as well as of much recondite information regarding the civil and religious usages of the ancient Romans. 3. *Sententiæ*, consisting of 165 pregnant sayings strung together, not by Varro himself, but probably by different hands at different times. 4. *Antiquitatum Libri*, comprising two sections, the *Antiquitates Rerum Humanarum*, in 25 books, and the *Antiquitates Rerum Divinarum*, in 16 books. This, the greatest work of Varro, and on which his reputation for learning was mainly founded, has unfortunately perished, all but a few fragments. From the 2d section St. Augustine drew much of his well-known work, the *City of God*. 5. *Saturæ*, composed in various meters, and occasionally in prose. These pieces, copied to some extent from the productions of Menippus the Gadarene, were apparently a series of comments on a great variety of subjects, generally conveyed in the form of dialogue, and aiming at the enforcement of some moral lesson or serious truth in a familiar and even jocular style. Of these we have only fragments; and of the other works little more than the titles. The best edition of the *De Re Rusticâ* is that of Schneider (Leip. 1794–97); of the *De Linguâ Latinâ*, that of Müller (Leip. 1833).

VARUN'A (from the Sanskrit *vr'i*, surround; hence, literally, "the surrounder," and kindred with the Greek *ouranos*) is, in the Vedic mythology of the ancient Hindus, one of the *Adityas*, or offsprings of *Aditi*, the deity of space, and among these, one of the

most prominent. He is often invoked together with *Mitra*, sometimes together with *Agni*, the god of fire, or with *Indra* (q.v.), or other elementary deities; but frequently he is also separately praised by the poets of the Vedic hymns. The character of Varuna, as is the case with other Vedic deities, does not appear to have been or remained the same throughout the whole period represented by the Vedic poetry; but, on the contrary, to have varied according as new imaginations were connected with the idea out of which he arose. Originally, *Varun'a* seems to have been conceived as the sun from the time after its setting to that of its rise; while *Mitra* probably represented the sun at its rise. The night is therefore said to be Varuna's, and the day Mitra's; and the "ever-going Varuna grants a cool place of rest to all moving creatures, on the closing of the eye (of *Savitr'i*, the sun)." As a consequence, the sun, as manifest during its daily course, is spoken of as his infant, and he "prepares a path for the sun;" and the dawn, which is called the golden light of Mitra and Varuna, "goes before Varuna." Out of the mysteriousness with which night is easily endowed, and the qualities which imagination may ascribe to the luminous origin of Varuna, then probably grew the moral attributes given to this deity; for he is extolled as the guardian of immortality; as the cherisher of truth; as armed with many nooses, with which he seizes evil-doers; as the forgiver of sins, and as having unlimited control over mankind. "No one rules for the twinkling of an eye apart from him, and he witnesses man's truth and falsehood. The functions of sovereign authority which are then also attributed to him are probably a consequence of his character as protector of the good, and punisher of the wicked; but his kingly might is, in some hymns, also associated with the power, predicated of him, of "setting free the water of the clouds," or of "ruling over the waters that are in heaven and earth." Whether the connection of Varuna with the element of water arose from the association of moisture with night, or, which is more likely, from the notion that water (*vâri*, from the same radical, *vr'i*, as Varuna) envelops or surrounds the earth, as darkness does, may be doubtful; but it is worthy of notice that the passages of the R'igveda in which Varuna is spoken of as the cause of rain, or as the lord of rivers or the sea, are few, and perhaps do not belong to the earlier portion of R'igveda poetry. See, for more detail, J. Muir's "Contributions to a Knowledge of the Vedic Theogony and Mythology," in the *Journal of the Royal Asiatic Society* for 1864. Compare also the article Vasisht'ha.—It is in this latter character alone, however, that Varuna appears in the classical and Purânic mythology; for there he has ceased to impersonate the sun, when invisible, and though, at that period too, he is still mentioned as an Aditya, his real quality is that of the regent of the waters, and more especially of the ocean, personified. As such, he retains, it is true, the Vedic qualities as "lord of punishment," and carries the "noose" to bind the wicked with; these attributes, however, are, then, not the reflex of his solar omniscience and power, but that of his might as the god of water.—Later fiction makes him also the regent of the west, probably in recollection of his Vedic character as the setting sun; and endows him with a wife, *Varun'âni*, a son, *Pushkara*, and sometimes also with a daughter, *Punjikasthalî*. It further gives him for a residence the fabulous mountain, *Pushpagiri*, "the mountain of flowers," and a marine monster, *Makara*, for his vehicle.

VARUS, Publius Quintilius, a Roman of noble birth, was appointed governor of Syria, and on his return from that post, was sent by Augustus to command the armies of Germany. His instructions, also, were to introduce into that country the regular administration of a Roman province. The Germans were indignant at his proceedings, and under the leadership of a chief of the Cherusci, named Arminius (Latinized from Herman), attacked Varus, who, with three legions, the usual number of auxiliaries, and a strong body of cavalry, had proceeded as far as the Weser. By false intelligence, the proconsul was induced to quit his intrenched camp. The Romans marched in a long straggling line, encumbered with baggage, with their wives and children. Suddenly, they were assailed by the Germans in a forest, and it was with difficulty they forced their way to a clear space to encamp for the night. For the next two days the Romans struggled on, marching and fighting, with decreasing forces, and exhausted strength, intending to reach, if possible, the fortress of Aliso on the Lippe. Near Kreutzberg, they were met by the main force of the Germans, and completely broken. Varus killed himself in despair. Augustus, who was now old and weak, is said to have yielded to transports of grief, calling upon Varus to give him back his legions. This victory of the Germans was gained 9 A.D., and rolled back the tide of Roman conquest. The Rhine, instead of the Weser, again became the boundary of the empire. The battle has ever since been a proud recollection for the Germans, and is known by the name of Herman-schlacht, that is, Herman's fight.

VA'RUS is a term employed in surgery to designate a variety of club-foot (q.v.). The corresponding Latin word signifies "having the legs turned inward, knock-kneed." It may be regarded as the opposite to valgus (q.v.), and as in the case of that word, *talipes* must be understood. In the form of club-foot termed varus, (1) the heel is raised; (2) the inner edge of the foot is drawn upward; and (3) the anterior part of the foot is twisted inward, so that the patient walks on its outer edge.

VAS, the Hungarian name of Eisenburg, a co. of Hungary, in the Trans-Danubian circle, bounded by Lower Austria, Styria, and Oedenburg, Veszprém and Zola counties;

It is crossed in the w. and s. by the Alps, and drained by the Raab. The soil produces grain, wine, and fruit. It takes its name from Vasvár, a free town and fortress under Matthias Corvinus. Pop. '90, 389,854. Capital, Szombathely.

VASA, a province of Finland, Russia, on the gulf of Bothnia; 16,084 sq.m.; pop. '94, 424,438. The surface is of level plains, with few lakes or rivers. Capital, Vasa.

VASARHELY, or HÓD-MEZÖ-VÁSÁRHELY, a city of Hungary, province of Czongrád, 5 m. from the left bank of the Theiss, and 16 m. n.e. of Szegedin. It has churches, a gymnasium, town hall, banks, hospitals, breweries, and oil factory. The city is rapidly rising into prominence. Pop. '90, 55,483, actively engaged in cattle-breeding, and in the cultivation of wine and tobacco.

VASARHELY, or MAROS-VÁSÁRHELY, a handsome t. of Transylvania, the largest of what are called the Szekler towns, and the center of Szekler political life, stands on the Maros, on a fruitful plain 60 m. n.n.e. of Hermanstadt. It has broad streets and well-built houses; excellent public schools, Protestant and Catholic—the latter richly endowed; a strong castle; and a choice public library founded by count Tekeli, and containing a fine museum of natural history. Tobacco, wine, and fruit are largely cultivated. Pop. '90, 14,212.

VASARI, GIORGIO, an Italian painter and author, was b. at Arezzo, in Tuscany, in 1511. He was a pupil of Michael Angelo's, and obtained the patronage of many distinguished persons, as cardinal Ippolito de' Medici, Clement VII., and the dukes Alessandro and Cosmo de' Medici; but his pictures possess no peculiar or distinctive merit, and his reputation rests exclusively on his *Vite de' più excellenti Pittori, Scultori, e Architetti* (Lives of the most excellent Painters, Sculptors, and Architects; Flor. 2 vols. 1550; 2d ed. by Vasari himself, 3 vols. 1568). This work is written, on the whole, in a simple and honest style; at times, it is even marked by a noble eloquence. The criticism is often admirable; and in spite of frequent inaccuracies (which, indeed, have been corrected by Della Valle, Rumohr, Förster, and others), it remains a model of art criticism and biography. Vasari died at Florence in 1574.—Bohn has published an English translation of Vasari, in 5 vols., forming part of the "Standard Library" series.

VASCO DA GAMA. See GAMA.

VASCULARES, in De Candolle's botanical system, the first of the two great divisions of plants, consisting of those in which vascular tissue (q.v.) appears, and thus including all the phanerogamous plants, both endogenous and exogenous. See CELLULARES.

VASCULAR TISSUE, in botany, that kind of vegetable tissue which is composed of closed tubes or vessels, elongated cells. The tubes have membranous walls of cellulose (q.v.), and within them are juices of the plant, which often deposit secretions. They are generally almost cylindrical—although sometimes prismatical from compression—except that they taper to a point at each extremity, preserving their character as cells by being closed at the extremities. They lie close together in bundles, and often overlie one another at the ends. The principal kinds of vascular tissue are woody fiber (q.v.) and laticiferous tissue, composed of the vessels which convey the latex (q.v.). Laticiferous tissue is generally composed of branched and anastomosing tubes, the walls of which are thin and delicate, extremely so in young plants. Many varieties of vascular tissue have, however, been distinguished by botanists, of which the most important are those classed under the name of *fibro-vascular tissue*, having spiral fibers in the tubes, winding up the inside of their walls as if to strengthen them. These fibers are elastic, and the coil can often be easily unrolled, at least while the tubes are young. Many fibers are often found in a single tube.

VASE (Lat. *vas*, Ger. *fass*), a term applied, in its widest signification, to all vessels adapted either for ornament or use. It is generally used in this sense with reference to ancient art; in connection with modern art, it is restricted to vessels of an ornamental kind. Few remains of antiquity have excited more interest than vases, particularly those of Greece, and of the Greek colonies and conquests. The names given by classical writers to vessels adapted for different purposes, have not always been easily identified with the ancient vases which have been preserved to us; but according to the nomenclature of M. Gerhard, which has generally been adopted, the following are the principal varieties, classified according to their uses: 1. Vases for holding wine, oil, or water, known under the names of *amphora* and *diota stamnos*. 2. Vases for carrying water, *hydria, calpis*. 3. Vases for mixing wine and water, *crater, kelebe, oxybaphon*. 4. Vases for pouring, *oinochoë, olpe, prochoüs*. 5. Drinking cups or goblets, *cantharus, kyathus, karchesion, holchion, kyphos, kylix, lepaste, phiale, keras, rhyton*. 6. Vases for ointments or perfumes, *lekythos, alabastron, askos, bomylios, aryballos, kotyliscos*.

The materials of which vases are formed include metal, stone, glass, and earthenware.

Vases of the precious metals were in use among the ancient Egyptians. Among the Greeks and Greek colonists of Asia Minor, they were very early employed for sacrificial purposes, and those of silver were frequently chased, an art in which considerable progress had been attained at a remote period. The general improvement in design in the epoch of Phidias, told in the chaser's art, the complete development of which was, however, according to Pliny, due to Polycletus. In the later period of the Roman republic, chased silver vases were more than ever in request; but under the empire,

chasing fell into disuse. Bronze, iron, and lead were all used as materials for vases. Bronze vases abounded among the presents made to the Greek temples; they were generally thin and hammered out, often decorated with inlaid ornaments or reliefs, among which mythological subjects and animal heads appear, and the handle sometimes assumed the shape of the human figure. Leaden vases were chiefly used for ungents or perfumes. The gold and silver vases of the first few centuries of the Christian era were, for the most part, imitations of pagan art. In the 12th c., a style was introduced, called *damascene* work, with patterns of gold or silver wire imbedded in iron or bronze. Many vases of this kind were made by Benvenuto Cellini.

Among the mineral materials which, plain and enriched, have been used both in ancient and modern times for vases, are marble, lapis lazuli, jasper; semi-transparent stones, such as opal, girasol, agate, chalcedony, sardonyx, cornelian; as also transparent gems and rock crystal. Multitudes of vases of precious stones were brought to Rome from the conquered provinces, particularly from Asia. Those in highest esteem were the *myrrhine* vases, whose material has been the subject of dispute among antiquaries; they are described by Pliny as brilliant, gem-like, and of various colors, generally purple and white, mingled with the iridescent hues of the rainbow. Precious stones have not ceased to be a material for vases; large and costly vases of malachite and jasper are manufactured in Russia; and elaborately carved vases are still made of the white alabaster of Volterra, in Tuscany.

Glass has at all times been a favorite material for vases. Small toilet-phials of opaque glass were in use in Egypt as far back as 1450 B.C. The cameo vases of Rome, of which the Portland vase is the most celebrated example, were composed of two layers of glass, the outer of which, being opaque, was cut down into groups of figures, delicately executed in relief. About the 3d c., we have, for the first time, the *diatreta*, or bored vases, with an external veil or network, almost detached from the rest of the glass. In the 5th c. occur vases composed of two layers of glass, with gilded subjects—often figures of Christ and legends of saints—between them. Vases of green glass, of a later period, with undercut projections, bearing a rude resemblance to the diatreta, have been found in tombs in England and France. Venice afterward acquired great celebrity for its glass vases. In the beginning of the 16th c., the Venetian glass-makers introduced a class of vases enriched with white or colored filigree work, having the appearance of being incrusted in the glass. They were much sought after all over Europe; and great care was taken to prevent the secret of their manufacture from being discovered. Beautifully enameled vases were also issued from the Venetian manufactories, as well as others of grotesque forms, representing imaginary animals, and pierced with holes or constructed in the form of a siphon, which are said to have been employed by alchemists, and in pharmacy and distillation. The German manufacturers, in the 16th c., produced vases with heraldic designs and inscriptions in enamel, generally cylindrical, and sometimes of considerable size, which are much prized by connoisseurs; in the following century, the designs became more artistic; and both in Germany and Italy, it was quite usual for distinguished artists to be employed to decorate these glass vases, in imitation of rock crystal, with ornaments, and arabesques. See POTTERY.

VASELINE, or petroleum jelly, is a residue from the distillation of petroleum, prepared by filtration. It is an amber-colored, translucent, semi-solid of the consistency of butter, melts at 37° C., is slightly soluble in alcohol, and readily dissolved by ether. It does not become rancid, and is largely used in pharmaceutical preparations, especially ointments, instead of the ordinary fats; is also extensively used for toilet articles. Lately it has been used by the bakers of Paris in the place of lard, because it ferments less quickly.

VASISHT'HA (the superlative of the Sanskrit *vasumat*, wealthy) is the name of one of the most celebrated Vedic R'ishis (q.v.), the author of several hymns of the R'igveda, and a personage who seems to have played an important part in the early history of the Brâhmanic or priestly caste of the Hindus. In the account given of him, historical events and mythological fictions are so much blended together that it is scarcely possible to gather more from it, for certain, than that he was a sage of high reputation, and a priest jealous of the privileges and the position of his caste, and ever ready to assert its superiority over the second or military and royal caste. In one of his R'igveda hymns he claims to have been enlightened by the god Varun'a; and in another he is called the son of *Mitra* and *Varun'a* (q.v.), born from the mind of *Urvas'î* (see PURÛRAVAS). In other Vedic passages his pre-eminence over other R'ishis, and his acquaintance with sacred and sacrificial knowledge are extolled. In the Mahâbhârata (q.v.), which also calls him the son of Mitra and Varun'a—whence his appellation there, *Maitrâvarun'i*—he is mentioned as imparting divine knowledge to king Janaka, and as the family priest of the race of Ikshwâku; and in the Purân'as he is said to have been one of the arrangers of the Vedas in the Dwâpara age. In Manu and the Purân'as (q.v.), he becomes a patriarch, one of the nine mind-born sons of the god Brâhman; and, according to some, marries Urjâ (strength); according to others, *Arundhatî*, one of the Pleiades, by whom he has seven sons. Various other legends relating to him always endeavor to impress the Hindu mind with his Brâhmanic power over kings and Kshattriyas generally. Thus, so great was his power, as the Raghuvans'a relates, that when king Dilîpa was doomed to remain childless, because he had inadvertenty;

offended the fabulous cow Surabhi, he was released of this curse by faithfully attending on the cow of Vasisht'ha, which was the cow of plenty, and an offspring of Surabhi. But the most interesting episode of his life is that relating to his conflict with *Vis'wâmitra* (q.v.). A Vasisht'ha is also mentioned as the author of a law-book; but whether he is, or is intended to be, the same personage as the ancient sage, may be doubtful. The name is often written *Vas'isht'ha*, when it would be the superlative of *Vas'a*, meaning "the most humble"—which the epic and Purânic Vasisht'ha certainly was not—or of *Vas'in*, meaning "the sage who has thoroughly subdued his passions"—which, too, would seem to be a rather strange epithet of the irascible saint. But though the name of the owner of the cow of plenty, who could obtain anything he desired, is doubtless correctly spelled Vasisht'ha, the less correct spelling must nevertheless have been current for a considerable time, since so early a poet as Kâlidâsa (q.v.), in his Raghuvans'a, puns on the words *vas'i vas'isht'ha*, "Vasisht'ha, the sage with subdued passions."—See, for the legends concerning Vasisht'ha, J. Muir's *Original Sanskrit Texts*, vol. i. (1858).

VASQUEZ DE CORONA'DO, Francisco, 1505–42; b. Spain; came to New Mexico, which he explored. In the hope of finding treasures among the Indians, he headed an expedition which started from Culiacan on the Pacific, early in 1540, traversed Sonora, crossed the Gila, and came to the cities of Cibola. He did not, however, find the expected treasure. He sent to Spain drawings of these cities, and an account of his expedition, which contains the first description of the buffalo. On his journey back from the city of Quivera he fell off his horse and was killed.

VASSAL (Celtic, *gwâs*, a youth or page), in the feudal system, is the correlative of suzerain (q.v.). See also Feu; Feudal System.

VASSAR, Matthew, 1792–1881; b. England; emigrated to this country in 1796. He succeeded his father in the brewing business near Poughkeepsie, and acquired a great fortune, $800,000 of which he gave for the establishment and endowment of the college for women which bears his name.

VASSAR COLLEGE. A non-sectarian institution for the higher education of women, founded by Matthew Vassar, near Poughkeepsie, N. Y., in 1861, but was not fully organized until 1865. It is situated two miles east of Poughkeepsie, with which it is connected by electric cars. There are 400 acres of grounds. The college buildings comprise the main building, a structure 500 feet long, containing the chapel, library, parlors, offices, etc.; Strong Hall and Raymond House, for residence; the Vassar Brothers' laboratory of physics and chemistry; the museum, with its collections, art-galleries, music-rooms, etc.; the recitation hall; the observatory; the alumni gymnasium; the conservatory; the lodge; residences for the president and professors; and other structures. The library of the college contains some 25,000 carefully selected volumes, and has connected with it a reading-room. There are a number of endowed scholarships for the assistance of students, besides two special funds of $50,000 each, and several of smaller amounts. The regular course of study leads to the baccalaureate degree, but special students are also admitted to the different departments. The college likewise provides for graduate instruction leading to the degree of A.M. In 1897, the professors and other officers of instruction and government numbered 57; and the students (graduate and undergraduate), 543. President, the Rev. James M. Taylor, D.D., LL.D.

VASSILKOV', a t. of Little Russia, in the government of Kiev, and 18 m. s.w. of the city of that name. This town, which was founded in the 10th c., contains tobacco and soap factories. Pop. about 18,000.

VAS'TO, or Il Vasto, a t. on the e. coast of southern Italy, in the province of Chieti, 26 m. s.e. of Ortona. It stands on a rising ground facing the Adriatic, from which it is distant 1½ m., is inclosed by walls, contains a spacious square with a handsome fountain, a handsome palace, a castle, and several churches. It has manufactures of silk, woolen goods, and earthenware. Pop. '81, 13,883.

VASUDEVA and **VÂSUDEVA**. See under Vishn'u.

VATER, Johann Severin, 1771–1826; b. Saxe-Altenburg, Germany; educated at Jena and Halle. He became a distinguished linguist, orientalist, and theologian; and held professorships at Jena, 1796; Halle, 1800–9 and 1820–26; and Königsberg, 1809–20. He published important works, of which the best known are his Russian, Polish, and Hebrew grammars, and the *Literatur der Grammatiken, Lexika, und Wortersammlungen aller Sprachen der Erde.*

VATE'RIA. See Tallow Tree.

VATICAN, Palace of, in Rome, the principal residence of the pope, and the seat of the great library and the museums, and collections of art, ancient and modern, which, for visitors, constitute one of the chief attractions of the city of Rome. The popes, very soon after the establishment of the peace of the church under the emperor Constantine, had a residence at the Vatican, which they occupied, although at uncertain intervals, conjointly with that of the Lateran. For a long time, however, through the mediæval, and especially the late mediæval period, the Vatican appears to have been

neglected. It was Nicholas V. who began that systematic scheme for the improvement and embellishment of the Vatican which has resulted in what, taken altogether, may be regarded as perhaps the noblest of princely residences. Alexander VI., Julius II., and above all, Leo X., pursued the same plan; and there are very few of the succeeding popes who have not had a share in the enlargement or embellishment of the Vatican. Amid all the difficulties, financial and political, of his pontificate, Pius IX. carried out many tasteful works of completion or restoration, the most striking and effective of which is the great stair by which it is approached from the colonnade of St. Peter's. The building, with its gardens and other appurtenances, is said to cover a space equal to the whole area of the city of Turin, such as it was thirty years ago, with a pop. of 130,000. It is popularly believed to contain 16,000 apartments of various sizes, but this is probably an exaggeration. Some of them, however, are of unrivaled beauty, among which may be particularized the chapel of San Lorenzo, the Pauline chapel, and the still more celebrated Sixtine chapel, which is decorated in frescoes from the pencil of Michael Angelo; the Sala Regia, the galleries and halls decoroted by Raphael, Giulio Romano, and their scholars; the magnificent library, which, although surpassed in the number of volumes, is unrivaled among the cities of Europe in extent, in beauty of proportions, and in decorations; the galleries of antiquities and of paintings, statuary, etc. The library was opened for historical research, under certain conditions, by Leo XIII. in 1883. Many descriptions of the Vatican have been published, and are to be found in all great libraries. An extremely interesting account, historical and descriptive. is to be found in Donovan's *Rome, Ancient and Modern;* see also Hare's *Walks in Rome*, and for recent additions and changes, Murray's *Handbook of Rome.*

VATICAN CODEX, one of the most valuable manuscripts of the Greek Scriptures, in uncial letters, belonging to the 4th century. Its marks of antiquity are the same as those of the Sinaitic codex, and the characters in both are very much alike. It is written on fine, thin vellum in beautiful square letters. It contains a large part of the Old Testament, and the New as far as Hebrews ix, 14. It has been in the Vatican library about three centuries. An edition prepared by cardinal Mai was published in 1857, after his death, but was found to be very erroneous. A new edition is now in progress under papal authority in beautiful style. The size and shape of the manuscript are preserved; and the printing is from the type cast for the imperial Russian edition of the Sinaitic codex.

VATICAN, COUNCIL OF THE (see COUNCIL). In 1867, more than 300 years after the council of Trent, Pope Pius IX. announced his purpose of holding another, the 20th ecumenical council. The period between this announcement and the publication of the pope's encyclical (June 29, 1868), definitely summoning the council, was replete with controversy regarding it, nor did the controversy become mute till the very date of the meeting. The liberal parties in the church, specifically the Jansenist, Gallican, and Old Catholic parties, as opposed to the Jesuitical and Ultramontane section —who were opposed to the subordination of the state to the church and of councils to the pope, vigorously contested the expediency of holding a council. Many of the prelates and of the general body of the clergy, especially of France, Belgium, Germany, and Holland, as well as many Catholic statesmen, gave voice to their opposition. Notably the court of Bavaria, under the inspiration of Dr. Döllinger, the leader of the Old Catholic party, combated the proposition in a vigorous circular addressed to Roman Catholic courts, showing the political bearings of the question. Austria united in discountenancing the projected meeting, and although Napoleon III. was not indisposed to it within certain limits, his ministry generally regarded it with distrust. Montalembert from his dying bed issued a voice of warning in opposition. The government of Italy opposed it openly. On the festival of the Immaculate Conception, 1869, amid thunders of artillery from San Angelo, and universal ringing of church bells the council held its first session in the basilica of the Vatican. There were present 719 prelates, 49 of whom were cardinals, 9 patriarchs, 4 primates, 121 archbishops, 479 bishops, and 57 abbots and generals of monastic orders This number gradually rose to 764, which was the greatest number of the 1,031 members invited who attended any one session. The deliberative sittings of the council, whether of the committees, or deputatory, or of the general congregation, were strictly private, but four public sessions were held at different times, when the decrees of the council were solemnly promulgated.

The subjects for discussion had been distributed by preparatory commissions under four heads (faith, discipline, religious orders, rites, including missions), each assigned to a separate committee of 26 members presided over by a cardinal; the reports of these committees on each specific point being laid before the general congregation, discussed, revised, adopted, and then, in public session and in presence and by authority of the pope, proclaimed to the public. Although the doctrine of infallibility had not been formally announced as a portion of the programme of the council till its actual convention, yet it may be said that the council had but two real objects. The solemn ratification of this dogma, and the utterance of a protest against infidelity in all its aspects, whether of rationalism, pantheism, materialism, or atheism. While the decrees setting forth the doctrines of the church regarding God, the creation, the relation of faith to reason, etc., were unanimously adopted in the third public session, April 24

1870, the decision in regard to infallibility was not arrived at so harmoniously, and not till a much later period.

It had been arranged that the committee on faith should consider all other matters lying within its sphere, relating to the church, before treating of its head and his prerogatives, but, April 29, the Italian bishops addressed a collective note to the council urging that all questions should give way to that of papal infallibility. The pope approved of this change, and ordered an inversion of the order of business accordingly. The debates on the subject agitated the council for some months, and the first vote was not arrived at till July 11, when, out of a court of 601 members, 88 voted "*non placet,*" or adversely. Influences were brought to bear on the non-conforming members, and these, combined with the threatened outbreak of the Franco-Prussian war, led many either to return to their dioceses, or, at least, to refrain from further attendance on meetings at which a vote was taken. On the final vote on the question, July 18, 1870, only two anti-infallible prelates recorded their votes; and even these, with all the rest of their recusant brethren, did ultimately, for the sake of unity and peace, acquiesce in the decrees of the church, henceforward known as the "Vatican decrees."

The decision on this matter arrived at by this great council may be summarized as follows: "The pope is superior to all councils; he is bishop of bishops, they being his vicars as he is vicar of Christ; when speaking on questions of faith and morals he is infallible, and his decisions irreformable and irreversible." A decision of such historic significance and so far-reaching in its consequences has not been issued by any former council: by it the Jesuits and Ultramontanes have gained a triumph absolute and decisive over their liberal opponents; but the ultimate fruits of such a victory can be developed only with the process of the ages. In the mean time it may be noted that it has placed the church and the government of Germany in direct antagonism, and one of the first results of the victory of the Jesuits was to procure their own expulsion from that country. The council was adjourned and indefinitely postponed, Oct. 20, 1870, in consequence of the outbreak of the Franco-Prussian war.

VATICAN DECREES. See VATICAN, COUNCIL OF THE.

VATTEL, EMERICH, a well-known writer on the law of nations, was born at Couret, in Neufchâtel, Apr. 25, 1714. His father, a Protestant clergyman, had been ennobled by the king of Prussia, whose subject he was. Vattel studied for the church at Bâle and Geneva, but he devoted greater attention to the writings of Leibnitz and Wolf than to those of the Calvinistic divines; and instead of becoming a country clergyman, he resolved to push his fortune at the court of Berlin, as a man of letters and diplomatist. In 1741 he offered his services to Frederick II., who had just ascended the throne, but there was then no vacancy in the public service. Three years afterward, he received an appointment at Dresden from the elector of Saxony, then also king of Poland; and in 1749 he was Saxon ambassador to Bern. In this post, he had ample leisure, and devoted himself to literary pursuits. He published, in French, under different titles, collections of essays on miscellaneous subjects, which are lively, and well written. But his chief attention for ten years was bestowed on his great work, the *Droit des Gens; ou Principes de la Loi Naturelle appliqués à la Conduite et aux Affaires des Nations et des Souverains.* This title sufficiently explains the scope of the work. It contained little that was new, but it abridged and systematized the doctrines of Grotius, Puffendorf, and Wolf. Vattel had, however, that skill in arranging his materials, and that power of lucid expression, which so often characterize French men of letters; and his book became rapidly popular as a text-book of international law. Like all his predecessors in the same field, Vattel based his whole system on an imaginary law of nature, and it would be easy to enumerate a large number of false conclusions to which he came in the absence of the light thrown on the law of nations by practice, and by the principle of utility in our time, so generally adopted as the test of international morality. After the completion of his great work, Vattel was recalled to Dresden, where he married, in 1764, Marianne de Chêne, and was promoted to the rank of privy-councilor. The duties of his new post proved too arduous, and he died of over-work on Dec. 28, 1767. Mr. Chitty republished, in 1833, an English translation of Vattel, with notes.

VAUBAN, SEBASTIEN LE PRESTRE, Marshal of France, the celebrated military engineer, was born at Saint Leger de Fougeret, in the dep. of Nievre, May 15, 1633; and being left an almost destitute orphan at the age of ten, his education was carried on under the auspices of the *curé* of his village. Leaving Saint Leger in 1651, he set out on foot to join Condé's army, then on the Belgian frontier; and during two years of active field service, obtained large insight into the engineering methods then in practice. Taken prisoner in 1653, he joined the royalists, and during the succeeding contest was mostly attached to the army of Turenne, who intrusted him with the sole control of the besieging operations; and the powerful assistance which the extraordinarily rapid reduction of the enemy's strongholds gave to the king's little army, gained for Vauban the repute of being the most promising young engineer of the time. On the conclusion of peace in 1660, he was dispatched to the w. to demolish the rebel strongholds in Lorraine, and to take charge of Breisach; but in 1667 he appeared again in the n., capturing one after another the powerful defenses of the Belgian frontier. About this period, the all-

powerful Louvois, charmed by Vauban's probity, punctuality, and habits of cool calculation, no less than by his genius, took him firmly by the hand; and it was as much owing to the great minister's favor as to the superiority of his designs that Vauban was preferred to the highly honorable and important office of fortifying the Flemish fortresses which had fallen into the possession of France. This labor accomplished in 1672, and the war with Holland resumed, Vauban took his old place as director of the siege operations, and for the first time introduced into practice in western Europe the method of approach by parallels (recently borrowed from the Turks), at the siege of Maestricht (1673), and with such effect, that that strong fortress capitulated in thirteen days. After tracing the plan of siege for Treves, and with remarkable sagacity foretelling the date when it *must* fall, he set himself with energy to strengthen the newly-acquired fortresses in the low countries, and closed a long and brilliant array of services for 1674 by throwing himself into Oudenarde, where William of Orange besieged him in vain. In 1675 he inaugurated a new era in military tactics by obtaining the creation of a corps of engineers, though the completion of the innovation by the establishment of companies of sappers was denied him. In 1676, he conducted the remarkable sieges of Valenciennes and Cambrai, stormed the latter in open day, against the unanimous opinion of the generals of the army; and two years later was rewarded for his long and glorious services by the appointment of director-general of fortifications. This post gave him the supreme control of the department of military engineering, and the ten years of peace which followed 1678 supplied opportunity for Vauban's rendering to France perhaps the greatest of his services, in surrounding the kingdom with a complete cordon of fortresses, fitted either for defense or for commanding weak points of the neighboring countries. At intervals during this period, he captured the almost impregnable fortress of Luxembourg, and planned and partly executed the magnificent aqueduct of Maintenon, by which the waters of the Eure are conveyed to Versailles.

War breaking out again in 1688, Vauban conducted the sieges of Philipsburg, Mannheim, and Frankenthal (introducing, at the last, his invention of ricochet-firing) Mons, (1691), and Namur (1692), with his usual success, though opposed at the last-named place by his great rival, Cohorn, who had fortified, and who defended it. After this period, Vauban almost disappears from the field of warfare, on which he had stood invincible for so many years, for the sieges of Charleroi (1693), Ath (1697), Breisach (1704), and the construction of the intrenched camp near Dunkirk (1706), are the only professional works of importance during the last 14 years of his life. After the peace of Ryswick in 1697, he had applied his active practical mind to the consideration of various deficiencies and anomalies in the internal government of France; and his zeal and research brought together a large mass of information and suggestion on numerous subjects, which was published under the curious title of *Oisivetés de M. de Vauban*, and contained recommendations for the collection of statistics of population, commerce, and agriculture, for supplying the army by recruitment, and valuable suggestions for improving the soil by drainage, etc., etc. Another of his works which excited an immense sensation at the time was the *Dime Royale* (1707), in which he discussed the question of taxation, and anticipated in the most striking manner the doctrines which, a century later, overthrew the French monarchy: such principles promulgated by a man of Vauban's sterling integrity and profound practical wisdom, could not be expected to be very palatable to the king and court of whose conduct they furnished indirectly the severest censure; and we are not therefore surprised to learn from Saint-Simon "that the marshal de Vauban was very ill received when he presented himself," and that, by an edict of Feb. 14, 1707, his book was seized and confiscated. Vauban did not long survive his disgrace, dying at Paris, Mar. 30, 1707. Fontenelle calculates that he had constructed 33 new fortresses, repaired 300 old ones, conducted 53 sieges, and had been present at 140 "actions of vigor;" and in his practice, the capture of a fortress was certainly a mere question of time and powder. His various professional works on the attack and defense of places, and on mines, have been collected under the title of *Œuvres Militaires* (Paris, 1796); and besides these we have various other memoirs on professional subjects from his pen. Historical notices and eulogies of Vauban are abundant in French literature. See *Nouvelle Biographie Générale.*

VAUCANSON, Jacques de, 1709–82, b. France; studied mathematics, and produced several curious mechanical inventions. Among them were a flute-playing automaton, and a duck that swam, quacked, etc., and could apparently digest its food. In 1741 he was made inspector of silk factories, and while in that position invented useful machines for dressing and weaving silk.

VAUCLUSE, a department in the s.e. of France, bounded on the w. by the Rhone, and on the s. by the Durance, which separates it from the department of Bouches du Rhone. Area, 1370 sq.m.; pop. '96, 236,313. The Rhone is the great river and its affluents, with the exception of the Durance, are all small. The department is traversed in the e. by spurs of the Alps. The plains are all in the w.—the chief being those of Orange, Carpentras, and Cavaillon. In the e., the mountains are separated by narrow, torrent-plowed valleys; and the summits, the chief of which is Mont Ventoux, 6,270 ft. high, are arid and bare. The climate is healthy and temperate, although sub-

ject to great variations—the winds from the n. and n.e. being sometimes very violent. The department, though more agricultural than manufacturing, does not produce cereals in great quantity; but the peach, pear, prune, almond, and fig trees bear excellent fruits. Olive, mulberry, and orange trees are quite common. Wines and honey, both held in high esteem, are produced. There are four arrondissements—Avignon, Apt, Carpentras, and Orange. Avignon is capital.

VAUD (Ger. *Waadt*), a canton which forms the western corner of Switzerland between the Jura and the Bernese Alps. Area, 1244 sq.m.; pop. '94, 256,242. It is a comparatively level district, traversed, however, by an elevated tract known as mount Jorat, from which plains slope on either side to the lake of Geneva on the s., and the lake of Neufchâtel on the north. On both sides, near the mountains, there are extensive pasture-lands, but the greater part of the country is highly cultivated. The orchards and vineyards are very extensive, the latter yielding white wines of excellent quality. Music boxes and watches are manufactured, and there are salt works. It is now traversed by railways, which connect it in two directions with France, and in three with the rest of Switzerland. It forms part of French Switzerland, the dialect spoken being the Vaudois. The religion is Protestant. Vaud has formed, since 1830, a democratic republic, the council of the canton being elected and controlled by the people. In 1845 and 1861 the rights of the people were still further extended. Vaud, after the fall of the Roman empire, formed part of the Burgundian kingdom. In the 13th c. it became a dependency of Savoy, to which it was annexed in 1359. In 1476 the house of Savoy took part with the duke of Burgundy in his struggle with the Swiss; and on his defeat, a part of Vaud was annexed to the adjoining cantons. In 1536 the Bernese took possession of the whole of Vaud, which they divided into 15 parts, administered by *baillis*, appointed at Bern. The nobility became patricians of Bern, and in this way acquired great influence. Still, the local councils had the power of appointing magistrates and administrative officers, which, to some extent, tempered the aristocratic character of the government. The French invasion put an end to the rule of Bern, and Vaud became a separate canton. The government remained in the hands of the higher classes until June, 1830, when a new constitution, granting a vote to every adult *bourgeois* of good character, was obtained from the council. The existing democratic-representative constitution dates from 1845. The Vaudois are industrious and well educated: and from this part of Switzerland come a large number of the Swiss teachers and governesses who are met with in all parts of the world. Capital, Lausanne (q.v.).

VAUDEVILLE, originally a popular song with words relating to some story of the day; whence it has come to signify a play in which dialogue is interspersed with songs of this description, incidentally introduced but forming an important part of the drama. The German *liedertafel* is a somewhat similar composition. The name vaudeville is a corruption of Vaux de Vire, the name of two picturesque valleys in the Bocage of Normandy. One Olivier Basselin, a fuller in Vire (q.v.), composed about the middle of the 15th c. a number of humorous and more or less satirical drinking-songs, which were very popular, and spread over France, bearing the name of their native place (Les Vaux de Vire). As the origin of the term was soon lost sight of, it at last took its present form. In the 16th c., Vauquelin still names such pieces Les Vaux de Vire.

VAUDOIS. See WALDENSES.

VAUDREUIL, a co. in s.w. Quebec, having the St. Lawrence river and the island of Perrol on the s.e., and the lake of Two Mountains on the n.; 182 sq.m.; pop. '91, 10,792. Co. seat, Vaudreuil.

VAUDREUIL, LOUIS PHILIPPE, DE **RIGAUD**, Marquis de, 1724–1802; b. France; entered the navy. He was in command of a vessel in the fight between Byron and D'Estaing near Granada in 1779, and that with Rodney near Martinique in 1780. He was in command of a squadron in the action between De Grasse and Graves, and in that with Rodney in 1782. He sat in the states general in 1789. He escaped to England, where he remained during the reign of terror.

VAUDREUIL, PHILIPPE DE **RIGAUD**, Marquis de, 1641–1725; b. France, of ancient family. He entered the army, and in 1687 was sent to Canada, then ranking as brig. gen.; he led expeditions against the Senecas, Oneidas, and other Indians in general with success. In 1698 he became governor of Montreal, and in 1703 governor-general of Canada. In this position he showed great executive ability, and defeated a naval expedition sent against Quebec.

VAUDREUIL, PIERRE DE **RIGAUD**, Marquis de, 1698–1764; b. Quebec, Canada; son of Philippe. He entered the French army, and in 1733 was appointed governor of the Trois Rivières. He became governor of Louisiana in 1742, succeeded to the title in 1748, and was made governor general of Canada in 1755. He vigorously resisted the attempts of Wolfe to capture Quebec; but, receiving no assistance from France, was forced to surrender. An official examination in France vindicated his conduct.

VAUGHAN, BENJAMIN, LL.D., 1751–1839; b. Jamaica; educated at Cambridge university, England; studied both law and medicine. He was a member of parliament, 1792–96. Dr. Vaughan wrote *The Rural Socrates*, and translated Poivre's *Travels of*

a Philosopher. He emigrated to this country, and accumulated a fine library, a large part of which he gave to Bowdoin college, near which he lived for the last 29 years of his life.

VAUGHAN, Charles John, d.d.; b. England, 1816; studied at Rugby school under Dr. Arnold; graduated Cambridge, 1838; fellow of Trinity, 1839; ordained in the church of England; had the living of St. Martin's, Leicester, 1841–44; head-master of Harrow school, 1844–59; vicar of Doncaster, 1861–69; chancellor of York cathedral, and chaplain in ordinary to the queen. He is one of the leaders of the "broad church," and distinguished as a preacher and commentator. He has published many volumes of sermons and expositions.

VAUGHAN, Henry, 1621–95; b. South Wales, entered Jesus college, Oxford, 1638; became a student at law at the Inns of Court, and studied medicine in London, withdrawing subsequently to his native place, Newton, in South Wales, where he became an eminent physician; also cultivating his favorite studies, and writing poetry on various subjects, chiefly devotional. The ancient inhabitants of South Wales were called "the Silures," and coming from that region, he adopted the name of "the Silurist," a name since received into the nomenclature of modern geology. Among his works which have been republished in our own day are *Poems with the Tenth Satyre of Juvenal Englished* (1646); *Olor Iscanus* (1651); *The Mount of Olives, or Solitary Devotions* (1652); *Thalia Rediviva* (1673). His verse, sometimes harsh, has a frequent charm of quaintness and a delicate force.

VAUGHAN, Robert, d.d., b. England, 1795; educated for the ministry at Bristol college; minister of Independent chapel, Kensington; professor of history in London university, 1830–42; president of the Independent college at Manchester, and professor of theology, 1842–57; the projector of the *British Quarterly* and its editor, 1845–65. His chief works are: *Life and Opinions of John de Wycliffe, D.D.; Memorials of the Stuart Dynasty; Causes of the Corruption of Christianity; The Protectorate of Oliver Cromwell; History of England under the House of Stuart; History of Revolutions in England; Memorial of English Nonconformity*. He d. 1868.

VAUGHAN, William, 1703–46; b. N. H.; graduated at Harvard, 1722. He was largely interested in the Newfoundland fisheries; took part in the Louisburg expedition of 1745, acting as lieut.col. of militia. Feeling slighted in the distribution of rewards, he went to England to present his claims, and there died.

VAULT, an arched roof, usually constructed of stone or brick-work. The simplest kind of vault is the plain wagon or tunnel vault, being a simple segmental or semicircular arch, thrown across a longitudinal apartment, and extending from one end to the other. Ordinary bridges show an example of this style of vaulting. Such vaults were commonly used by the Romans, who also built vaults with *groins*—i.e., vaults intersecting one another. See Groined Vaulting. The tunnel arch, of a pointed form, was of very ancient introduction, having been used by the Assyrians for vaulting their large drains.

The Egyptians are also said to have been acquainted with vaulting; but the earliest remains of ancient vaults of any magnitude are Roman works.

The Roman vaults, where groined, are usually constructed with carefully cut stone, so as to prevent the angle from chipping. The mediæval architects had not the costly materials or skill of the Romans at command, so they formed the groins only of dressed stone, and the filling in of the vault with commoner materials. This led to the groin becoming a prominent feature in mediæval architecture, being generally ornamented with moldings and carved work. We have already traced the progress of Gothic vaulting under the heads Gothic Architecture, Fan-tracery Vaulting, Rib, etc. Domical or hemispherical vaulting was also much used by the Romans. The Pantheon, in Rome, is the finest example remaining, being a circular building with a dome 142 ft. in diameter. Roman domes and vaults are frequently ornamented with sunk panels. During the renaissance period vaulting in great measure gave place to wooden roofs; but when employed, the domical or plain groined vaults of Roman architecture are chiefly used. In modern works vaults and arches are gradually becoming superseded by the use of iron construction, both for roofs and for supporting floors, bridges, etc.

VAULTING-SHAFT, a small column, or pillar, supporting the ribs of a Gothic vault. These shafts generally occur in clusters, and may either spring from the ground, or be supported on small corbels in the wall.

VAUMURE, in old fortresses, a low work under the wall in the nature of a *fausse-braye*.

VAUQUELIN, Jean, a French poet, was b. in 1535, of a noble family, at the château of La Fresnaye, near Falaise. He made a pretense of studying law at Poitiers, Paris, and at Bourges, but really spent his time in gayety and verse-making. He finally became president of the *présideal* bench at Caen, where he died in 1607. His *Œuvres Poétiques* contain many sportive songs and other light pieces, which are yet read with pleasure. He was the first writer of idyls in French verse, and is considered as the real founder of French satire, which he redeemed from the grossness that had hitherto characterized the productions that went under that name.

VAUTIER, Benjamin, b. Switzerland, 1829; studied art in Düsseldorf; became distinguished for his *genre* pictures of life in Switzerland and Swabia. Previous to 1864 he exhibited "Devout Singers in a Church;" "A Party embarking on a Rhine Steamer," etc. "Cats in a Criminal Case" is considered one of his best productions. At the Paris exhibition of 1867, where he exhibited his "Courtier and Peasants in Würtemberg," he received a medal. Among his latest works are "A Public Dinner;" "A Village Funeral," 1871; "Alsatian Woman," 1882; and "Abandoned," 1892.

VAUX, Calvert, b. London, 1824, educated in that city; came to the U. S. at the request of A. J. Downing, 1850, and practiced at Newburg with the latter till his death, 1852, and afterwards alone. In conjunction with F. L. Olmsted, Mr. V. prepared the design for the Central Park; in 1865 made a special report on the existing boundaries of Prospect Park, Brooklyn, which led to an entire change in its scope and character and the acceptance of his general scheme for its arrangement. In 1873 he was employed by the Canadian government to prepare the design which was executed for laying out the grounds and terraces of the Parliament buildings at Ottawa. He also designed the museum of natural history and the Metropolitan museum of art, in New York, and other notable buildings elsewhere. He d. in 1895.

VAUX, Richard, b. Philadelphia, 1816; son of Roberts V.; was recorder of his native city, 1842–49, mayor, 1856–58, and member of Congress, 1890–92. Although he held no office for many years, he was always a prominent democratic politician. He published a number of addresses, lectures, papers on social science, historical, humorous, and critical essays, and legal reports, and was well known as a penologist.

VAUX, Roberts, 1786–1836; b. Philadelphia, a member of the society of Friends. He was for a short time before his death judge of the county court. Most of his life was devoted to charity, to education, and to the reform of the penal code. He was an advocate of the so-called "separate system" of punishment. Among his works are: *Memoirs of the Life of Anthony Benezet* (1817); and *Notices of the Original and Successive Efforts to Improve the Discipline of the Prison at Philadelphia* (1826).

VAUX, William Sandys Wright, b. England, 1818; educated at Westminster and Oxford. He entered the department of antiquities in the British museum in 1841; was made keeper of the department of coins and medals in 1861, and resigned in 1870. Among his works are: *Nineveh and Persepolis; Persia, from the Earliest Period to the Arab Conquest* (1875); and *Greek Cities and Islands of Asia Minor* (1877). He d. 1885.

VAUXHALL', a famous public garden in London, constituted as such immediately after the restoration (May, 1660), and supporting that character for nearly two centuries. It was situated in Lambeth, opposite Millbank, and near the manor called Fulke's Hall (the residence of Fulke de Breauté, a follower of King John), from which is derived the name Vauxhall. Pepys, writing May 28, 1667, describes the garden, and concludes that the entertainments there to be had are "mighty devertising." But the pastimes of Vauxhall were not always of a merely "devertising" description. The eating, drinking, dancing, and flirtation that continually went on there led to much quarreling and dissipation.

VA'VASOUR, or Valvassor (derived, like *vassal*, from Celtic *gwâs*, a youth or page), a term of feudal times, more in use in the continent of Europe than in England, employed somewhat loosely, and defined by Camden as the rank next below a baron. Its usual meaning was one who held his lands, not directly of the crown, but of one of the higher nobility. In this class were comprehended the *châtelains*, who owned castles or fortified houses, and possessed rights of territorial justice.

VÂYU (from the Sanskrit *vâ*, blow), the wind, is, in the Vedic mythology of the Hindus, a deity, which originally seems to have held an equal rank with Indra (q.v.), but much more rarely occupies the imagination of the poets than this god, or Agni, or the sun; for though, according to Yâska (q.v.), ancient commentators of the Vedas hold that there are only three great deities—viz., *Agni*, fire, whose place is on earth; *Sûrya*, the sun, whose place is in heaven; and *Vâyu*, or *Indra* (q.v.), whose place is in the intermediate sphere—only a few hymns, comparatively speaking, are dedicated to Vâyu, whereas the other deities named are the subject of manifold praise. The description given by the R'igveda of the greatness of Vâyu nevertheless answers the position which those ancient commentators assign to him.—See J. Muir's "Contributions to a Knowledge of the Vedic Theogony and Mythology," in the *Journal of the Royal Asiatic Society* for 1864. In the epic and Purânic mythology, Vâyu occupies but an inferior position, and the legends there related of him have no cosmical character. They give him a wife, *Anjanâ*, by whom he has a son, the monkey *Hanuman* (q.v.).

VAYU-PURÂN'A. See Purân'a.

VEDA (from the Sanskrit *vid*, know; kindred with the Latin *vid-*, Greek *id-*, Gothic *vait-*, Lithuanian *weizd-;* hence, literally, knowledge) is the technical name of those ancient Sanskrit works on which the first period of the religious belief of the Hindus is based. See India, sec. *Religion*. The oldest of these works—and in all probability the oldest literary document still existing—is the *R'igveda;* next to it stand the *Yajurveda* and *Sâmaveda;* and the latest is the *Atharvaveda*. The first three also bear the collective title of *trayî*, or "the threefold" (scil. science); and all four are considered to be of

divinely inspired origin. Each of these Vedas consists of two distinct divisions—a *Sanhitâ*, or collection of *mantras*, or hymns; and a portion called *Brâhman'a*. A *mantra* (from *man*, think; hence, literally, the means by which thinking or meditation is effected) is, as Colebrooke, in conformity with the Mîmânsâ writers, defines the word, a prayer, or else a thanksgiving, praise, or adoration addressed to a deity: it declares the purpose of a pious act, or lauds or invokes the object; it asks a question, or returns an answer; either directs, inquires, or deliberates, blesses or imprecates, exults or laments, counts or narrates, etc. Sometimes it is addressed to the deity with a verb in the first person; sometimes it ends with the verb "thou art," or with the word "thee." See Colebrooke, *Miscellaneous Essays*, i. p. 308; Müller, *Ancient Sanskrit Literature*, p. 343; Jaiminiyanyâyamâlâvistara, as quoted in Goldstücker's *Pân'ini*, p. 69. If such a *mantra* is metrical, and intended for loud recitation, it is called *R'ich* (from *r'ich*, praise)—whence the name *R'igvedâ*, i.e., the Veda containing such praises—if it is in prose, and then it must be muttered inaudibly, it is called *Yajus* (from *yaj*, sacrifice; hence, literally, the means by which sacrificing is effected); therefore, *Yajurveda* signifies the Veda containing such *yajus*. And if it is metrical, and intended for chanting, it is termed *Sâman;* whence *Sâmaveda* means the Veda containing such sâmans. (The original meaning of the latter word is obscure. Native grammarians derive it, but without much probability, from *so*, to give pain, because, they say, "it is difficult to utter such mantras." A mystical, but grammatically impossible, account of *sâman* is given in the *S'atapatha-brâhman'a* and *Br'ihadâran-yaka*, where the word is analyzed into *sâ* and *ama*, the former being interpreted as implying "speech," and the latter "breathing forth," since the chanting of the sâman, as the commentator says, is essentially the result of both.) No special name is given to the mantras of the fourth Veda. The author of the mantra, or, as the Hindus would say, the inspired "seer," who received it from the deity, is termed its *R'ishi* (q.v.); and the object in which the mantra is concerned is its *devatâ*—a word which generally signifies "deity," but the meaning of which, in its reference to the mantras, must not always be taken literally, as there are hymns, in which not gods or deified beings, but, for instance, a sacrificial post, a remedy against bad dreams, the generosity of princes from whom gifts were received by the authors, or a chariot, a drum, weapons, the charioteer and horses employed in war, and other worldly objects, invoked, are considered as the *devatâ*.—See Colebrooke's *Misc. Essays*, i. p. 22; Wilson's *Rigveda*, vol. i., in the edition of F. E. Hall, p. 347.—*Brâhman'a*—derived from *brahman*, neuter, probably in the sense of prayer or hymn (see concerning this word, J. Muir, "On the Relation of the Priests to the other Classes of Indian Society in the Vedic Age," in the *Journal of the Royal Asiatic Society* for 1864; and the introduction of M. Haug's edition of the Aitareya Brâhman'a vol. i. p. 4)—designates, according to *Mâdhava-Sâyan'a*, the great commentator on the Vedas, that portion in prose of the Vedas which contains either commandments or explanations; or, in other words, which gives injuctions for the performance of sacrificial acts, explains their origin, and the occasions of which the mantras had to be used, by adding sometimes illustrations and legends, and sometimes also mystical and philosophical speculations. The *Brâhman'a* portion of the Vedas is therefore the basis on which the Vedic ritual rests (see KALPA and VEDÂNGA), and whence the *Upanishads* (q.v.) and the philosophical doctrines (see SANSKRIT LITERATURE) took their development.

Though *Mantras* and *Brâhman'as*—both of which are also termed *S'ruti* (q. v.)—were held at a later period of Hinduism to have existed simultaneously, that is, from eternity, it is certain that the Brâhman'a portion of each Veda is posterior to at least some part of its Sanhitâ, for it refers to it; and it scarcely requires a remark that so great a bulk of works as that represented by both portions must have been the gradual result of a considerable period of time. There is, indeed, sufficient evidence to prove that various conditions of society, various phases of religious belief, and even different periods of language are reflected by them. The difficulty, however, critically to discern these periods, is enhanced by the losses, probably considerable, which these writings suffered before they were preserved in the shape in which we now possess them. For in tradition, which records that *Vyâsa* (q.v.), after having compiled and arranged the Vedas, handed each of them to four disciples, and that these disciples taught them to their disciples, and so forth, down to distant ages, there is so much indubitable, that Mantras and Brâhman'as had to pass through a large number of S'âkhâs, or schools, and that the discrepancies which gradually arose between these schools, both as regards the Vedic texts and the interpretation of these texts, cannot have been slight; for, apart from the conclusion yielded by a comparison of the remaining texts of some of these schools, later writers afford us an insight into the animosity which existed between these schools, and must have arisen from very material grounds. Thus, in a commentary on *Páraskara's Gr'ihya Sútras*, it is said: "Vasisht'ha declares that it is wrong to follow the rules of another S'âkhâ." He says: "A wise person will certainly not perform the duties prescribed by another S'âkhâ; he that does is called a traitor to his S'âkhâ. Whosoever leaves the law of his S'âkhâ, and adopts that of another, he sinks into blind darkness, having degraded a sacred R'ishi." And in another law-book it is said: "If a man gives up his own customs, and performs others, whether out of ignorance or covetousness, he will fall, and be destroyed." And again in the *Paris'ish't'a* of the *Chhandogas:* "A fool who ceases to follow his own S'âkhâ, wishing to adopt another one, his work will be in vain."—See Müller's *Ancient Sanscrit Literature*, p. 51. That each *S'âkhâ* claimed

the possession of the only true and genuine Veda, may be already inferred from passages like these. The difference between these S'âkhâs, however, did not consist—as has been believed—in their various readings of the S'ruti alone: it also consisted in considerable variations of their arrangement of the Scriptures; in their additions or omissions of texts—as may be seen from still existing S'âkhâs of the Yajurveda—and, as is stated by *Madhusûdana*, and results from a commentator on Pân'ini, in their *different interpretation of the Vedic texts*. How great the number of these S'âkhâs was, may be inferred from the statement of the *Charan'avyûha*, a treatise ascribed to an ancient writer, S'aunaka; for it enumerates five S'âkhâs of the R'igveda; says that there were 86, and names 42 (or in one recension 44) of the Yajurveda; mentions twelve of the Sâmaveda, out of a thousand, which, it says, were at one time in existence, and nine of the Atharvaveda. The *Atharvan'arahasya*, a modern treatise on the Atharvaveda, while ascribing the same number of Sâkhâs to the Sâmâveda and Atharvaveda, speaks of twenty-one of the Ri'g-veda, and a hundred of the Yajurveda. Of all these schools, however, the *R'igveda* is now extant only in one; the *Yajurveda* (both divisions to be named hereafter, taken collectively) in three and partially in four; the *Sâmaveda* in perhaps two; and the *Atharvaveda* in one.

The character of the Sanhitâ or Mantra portion of the four Vedas—on which their Brâhman'a portion is based—as well as the relation in which these Sanhitâs stand to each other, is intelligible only if it is borne in mind that the ancient Hindu believed to secure the favors of his gods chiefly by the performance of sacrificial rites; that gradually these rites became complicated and manifold, and that special care, therefore, had to be taken to provide for a correct celebration of the sacrifices which had sprung up, and also to guard against the evil consequences which might result from inadvertence, or other causes beyond the sacrificer's control. The original worship seems to have been simple enough (see INDIA, sec. *religion*)—it probably neither occupied much time, nor required the assistance of a priest. But when sacrifices were instituted which lasted from one day to eleven, nay, to a hundred days—and some works speak of sacrifices which went on for the space of one and even several years—and when the Brahmanic caste found the performance of such sacrifices to be an excellent means of establishing its sway over the other castes, and a convenient source of an easy livelihood, it was laid down as a rule that no sacrifice could be performed without one *R'itwij*, or priest; and that a great sacrifice, such as the Jyotisht'oma, Râjasûya, or other sacrifices which could only be celebrated by wealthy people or kings, required the assistance of not less than sixteen priests, besides a number of menials, who had to slay the sacrificial animals, to chant, or to perform other inferior work. These sixteen priests were then divided into four sections, each headed by one R'itwij, and containing besides him, his three purushas, or assistants. The first section consisted of the *Adhwaryu*, with his three purushas, the Pratiprasthâtr'i, Nesht'r'i, and Unît'ri; the second, of the *Brahman*, with the three purushas, Brâhmanâchchhansin, Agnîdh (or Agnîdhra), and Potr'i; the third, of the *Udgâtr'i*, with the Prastotr'i, Pratihartr'i, and Subrahman'ya; and the fourth of the *Hot'ri*, whose assistants were the Maitrâvarun'a, Achchhâvâka, and Grâvastut. (In other accounts the order of these sections varies, and in the section headed by the Brahman, the Potr'i precedes the Agnîdh; see also Müller, *Ancient Sanscrit Lit.*, pp. 468–69; where, however, by mistake, some of the assistant priests occur in the wrong sections.) The principal duties of these priests were further regulated in the following manner. The *Hot'ri* had to perform the rites relating to the R'igveda, the *Adhwaryu* those based on the Yajurveda; the *Udgâtr'i* was concerned in the rites of the Sâmaveda; and the Brahman had to possess a knowledge of all these three Vedas, and to set right any mistake that might have occurred in the performance of the ritual acts, or remedy any defect which might vitiate the efficiency of the sacrifice. He was therefore the most learned of all the priests; and the R'igveda itself, though perhaps in one of its latest portions, recognizes the superiority of the priest Brahman. In the ritual works relating to the first three Vedas, no functions based on the use of the latest or the Atharvaveda are assigned to him, but in the *S'aunaka-Brâhman'a* of the *Atharvaveda*, where Prajâpati is introduced as intending to perform a soma sacrifice, and asking the Vedas whom he should choose for his Hot'ri, Adhwaryu, Udgâtr'i, and Brahman, the Vedas answer him: "Choose for a Hot'ri (the priest) who knows the R'igveda; for an Adwaryn, (the priest) who knows the Yajurveda; for an Udgâtr'i,(the priest) who knows the Sâmaveda; and for a Brahman (the priest) who knows the Atharvaveda;" and to explain the reason for such advice, they add that the R'igveda hymns having the earth for their abode, one who chooses a *Hotr'i* will obtain dominion over the earth; the Yajurveda mantras resting on the intermediate space, one who engages an *Adhwaryu* will obtain the world of that space; the Sâmaveda hymns dwelling on heaven, one who employs an *Udgâtr'i* will obtain that world; but one who chooses a *Brahman* will encompass the world of (the neuter) Brahman, or the supreme spirit, since the hymns of the Atharvaveda have for their abode Brahman.

The most interesting feature of this and similar passages is the tendency of their authors to maintain the greater efficiency of one of the later Vedas in comparison to that of the R'igveda, and consequently the greater practical superiority of these Vedas over the avowedly oldest Veda. And this is intelligible enough if we compare the contents of these Vedas.

The worship alluded to in many hymns of the R'igveda must have consisted more of isolated sacrificial offerings than of a series of acts strung together so as to form an elaborate sacrifice. There are other hymns, it is true, which betray the existence, at their time, of a ritual, already become complicated, as when three or four, or even seven, priests are mentioned by the poet; but though these hymns, as well as the former, bear testimony to the existence, at that early period, of ritual acts, it does not follow that the R'igveda, as such, was composed for the purpose of being recited when they were performed. From the nature of its hymns, it results, on the contrary, that, having been composed, they were at some subsequent period connected with those pious acts which became more and more complicated, and gradually were systematized. But then even there remain verses which would not easily bend to such artificial purposes; and whole hymns, too, which would resist an attempt to force them into a liturgic code for which they were not intended by the poet's mind. A collection of songs, in short, which was the natural growth of time, and, to some extent, at least, the ingenuous outburst of the poets' feelings, became inadequate for a regular liturgy of a highly-developed and throughout artificial ritual. Out of this necessity there arose the *Sâma-* and the *Yajurveda*. The former was entirely made up of extracts from the R'igveda, put together so as to suit the ritual of the so-called Soma sacrifices. For, as all native authorities agree in stating that the Sâmaveda contains none but R'igveda verses, the absence of 71 verses in the recension of this Veda, edited by prof. Benfey, from the recension in which the R'igveda now exists, does not disprove their unanimous statement: it must be accounted for by the circumstance that these verses belonged to one or the other of the recensions of the R'igveda, which, as mentioned before, are no longer preserved. The origin of the Yajurveda is similar to that of the Sâmaveda; it, too, is chiefly composed of verses taken from the R'igveda; but as the sphere of the ritual for which the compilation of this Veda became necessary is wider than that of the Sâmaveda, and as the poetry of the R'igveda no longer sufficed for certain sacrifices with which this ritual had been enlarged, new mantras were added to it—the so-called Yajus, in prose, which thus became a distinctive feature of this Veda; and it is on the Yajurveda, therefore, that the orthodox Hindu looked with especial predilection, for it could better satisfy his sacrificial wants than the Sâma-, and still more, of course, than the R'igveda. "The Yajurveda," says *Sâyan'a*, in his introduction to the Taittirîya Sanhitâ, "is like a wall, the two other Vedas like paintings (on it)." The sacredness of the Sâma- and Yajurveda, and the belief in their inspired character, rest on the assumption that they are of the same origin as the R'igveda, which dates from eternity, and which was "seen" by the R'ishis who uttered it. That, in the case of the Yajurveda, this theory is only partially correct, results already from the description just given of it; for whatever losses the present text of the R'igveda may have suffered, it is admitted by all authorities that its mantras were always metrical, and that it can never, therefore, have possessed passages in prose. But how frail this theory is, and in what sense it is possible to speak of the sameness of origin even in the case of those hymns of the Sâma- and Yajurveda which are composed of R'igveda verses, a comparison of the place occupied by the verses of a few hymns taken from one and the other of these Vedas with the place which the same verses occupy in the R'igveda, will sufficiently show.

The first hymn of the Sâmaveda consists of ten verses, nine of which are contained in the present recension of the R'igveda. If by the side of each of these verses the place is marked which it holds in the R'igveda, the result is this:

	Book.	Hymn.	Verse.
Sâmaveda 1, verse 1, is R'igveda	6	16	10
" " 2, "	6	16	1
" " 3, "	1	12	1
" " 4, "	6	16	34
" " 5, "	8	73	1
" " 6, "	8	60	1
" " 7, "	6	16	16
" " 8, "	8	11	7
" " 9, "	6	16	13

The verses of which the hymn of the Sâmaveda 1, verses 370–380, is composed, correspond with the following verses of the R'igveda:

	Book.	Hymn.	Verse.
Sâmaveda 1, verse 370, with R'igveda	8	86	10
" " 371, "	10	147	1
" " 372, "		absent	
" " 373, "	1	57	4
" " 374, "	3	51	1
" " 375, "	10	43	1
" " 376, "	1	51	1
" " 377, "	1	52	1
" " 378, "	6	70	1
" " 379, "	10	134	1
" " 380, "	1	101	1

If from the White Yajurveda the mantras, for instance, of the 22d to the 25th chapter were submitted to a similar test, it would be seen that in chapter 22, which has 34 divisions, only four verses occur in the R'igveda, viz.:

	Book.	Hymn.	Verse.
White Yajurveda 22, verse 10, in R'igveda	1	22	5
" " 15, "	5	14	1
" " 16, "	3	11	2
" " 18, "	9	110	3

that in chapter 23, with 65 divisions, there correspond:

	Book.	Hymn.	Verse.
White Yajurveda 23, verse 3, with R'igveda	10	121	3
" " 5, "	1	6	1
" " 6, "	1	6	2
" " 16, "	1	162	21
" " 32, "	4	39	6

that of chapter 24 being in prose, cannot occur in the R'igveda; and that of chapter 25, with 47 divisions:

	Book.	Hymn.	Verse.
White Yajurveda 25, verse 12, is R'igveda	10	121	4
" " 13, "	10	121	2
" " 14–23 are "	1	89	1–10
" " 24–45 "	1	162	1–22
" " 46 is "	10	157	1, 3, 2

(See the article "The Inspired Writings of Hinduism," in the *Westminster Review* for Jan., 1864.)

All, therefore, that is left of the oldest Veda in the Sâmaveda and Yajurveda, is a R'igveda piecemeal; its hymns scattered about; verses of the same hymn transposed; verses from different hymns combined, and even the compositions of different poets brought into one and the same hymn, as if they belonged to the same authorship. That, under such treatment, the Yajurveda should have lost all poetical worth, is but what may be expected; it must be, however, matter of surprise that the Sâmaveda should have saved so much, as it even now possesses, of that genuine beauty which distinguishes the R'igveda poetry. The *Atharvaveda*, too, is made up in a similar manner as the Yajurveda, with this difference only, that the additions in it to the garbled extracts from the R'igveda are more considerable than those in the Yajurveda. It is avowedly the latest Veda, and even its name, "Atharvaveda," as it was current already during the classical period of Sanskrit literature, does not yet occur in the oldest Upanishads (q.v.), where only the songs or revelations of the *Atharva-Angiras*, or of the *Bhr'igu-Angiras*, apparently denoting this Veda, are spoken of. The Atharvaveda was not used, as Madhusûdana, in his treatise on Sanskrit literature says, "for the sacrifice, but merely for appeasing evil influences, for insuring the success of sacrificial acts, for incantations, etc.;" but on this very ground, and perhaps on account of the mysteriousness which pervades its songs, it obtained, among certain schools, a degree of sanctity which even surpassed that of the older Vedas.

This being the general character of these four Vedas, a few remarks must here suffice to convey some idea of their special contents.

On the religious ideas expressed in the *R'igveda*, a general account is given in the article INDIA, sec. *Religion;* see also, besides the deities mentioned there, and the articles referring to them, VARUN'A, VÂYU, and YAMA, and J. Muir's "Contributions to a Knowledge of Vedic Theogony and Mythology," in the *Journal of the Royal Asiatic Society* for 1864. The social condition of the Hindus, as reflected from the hymns of this Veda, is not that of a pastoral or nomadic people, as is sometimes supposed, but, on the contrary, betrays an advanced stage of civilization. Frequent allusion is made in them to towns and cities, to mighty kings, and their prodigious wealth. Besides agriculture, they mention various useful arts which were practiced by the people, as the art of weaving, of melting precious metals, of fabricating cars, golden and iron mail, and golden ornaments. The employment of the needle and the use of musical instruments, are known to them. They also prove that the Hindus of that period were not only familiar with the ocean, but sometimes must have engaged in naval expeditions. They had some knowledge of medicine, and must have made some advance in astronomical computation, as mention is made of the adoption of an intercalary month, for the purpose of adjusting the solar and lunar years. Nor were they unacquainted with the vices of civilization, for we read in these hymns of common women, of secret births, of gamblers and thieves. There is also a curious hymn, from which it would follow that even the complicated law of inheritance, which is one of the peculiarities of the existing Hindu law, was to some extent already in use at one of the periods of the R'igveda hymns. The institution of caste, however, seems at that time to have been unknown, for there is no evidence to prove that the names which at a later period were current for the distinction of caste, were employed in the same sense by the poets of these hymns.—See Wil-

son's *R'igveda*, vol. i., re-edited by F. E. Hall, vols. ii., iii.; and vol. iv., edited by E. B. Cowell (Lond. 1850–66).

The only recension in which the Sanhitâ of the R'igveda has been preserved to us, is that of the *S'ákala* school; and the hymns themselves are arranged according to two methods, the one chiefly considering the material bulk, the other the authorship of the hymns. Both divisions, however, run parallel. According to the former, the whole Sanhitâ consists of eight *Asht'akas*, or eights; these, again, are divided into 64 *Adhyáyas*, or lessons; these into 2,006 *Vargas*, or sections; and the Vargas into *R'ichs*, or verses, the actual number of which is 10,417, but, according to the statement of native authorities, seems at some other time to have amounted to 10,616 or 10,622.—According to the other method, the Sanhitâ is divided into 10 *Man'd'alas*, or "circles;" the Man'd'alas into 85 *Anuvákas*, or "sections;" these into 1017, and 11 additional, i.e., into 1028 *Súhtas*, or "hymns," and the hymns into *R'ichs*, or verses, the number of which coincides, of course, with that of the former arrangement. The number of *padas*, or words, in this Sanhitâ is stated as being 153,826.

In eight out of the ten Man'd'alas, the first hymn or hymns are addressed to *Agni;* the next hymn or hymns generally to *Indra;* and after these come hymns to the *Vis'we Devás*—the deities collectively—or hymns to other special deities. The eighth Man'd'ala begins with hymns to Indra, and the ninth is chiefly devoted to Soma.

As for the authorship of the hymns, the second Man'd'ala belongs chiefly to that of *Gr'itsamada*, the third chiefly to that of *Vis'vámitra*, and the fourth chiefly to that of *Vámadeva*. The fifth was composed chiefly by *Atri*, and members of his family; the sixth by *Bharadvája* and members of his family; the seventh by *Vasisht'ha* and his kin; the first, eighth, ninth, and tenth by various R'ishis.—The text of the Sanhitâ has been edited in Roman characters by Prof. Th. Aufrecht (Berlin, 1861); and the text, with a commentary of Sâyan'a, is published by Prof. Max Müller, there having already appeared vols. i.–vi. of this edition (Lond., 1849–74). Of translations, the first volume of one by Max Müller appeared in 1869; that by the late Prof. H. H. Wilson, which was left by him completed in manuscript, follows the commentary of Sâyan'a, based on Hindu tradition; that begun by Prof. Benfey in the Journal *Orient und Occident*, vols. i. and ii. (Gött. 1862–64), is essentially speculative.

The Brâhman'a portion of the R'igveda is preserved in two works only—the *Aitareya Brâhman'a*, which consists of eight *Panchikás*, or "pentades," each of these comprising five *Adhyáyas*, or "lessons," and all the Adhyâyas together, 285 *Khan'd'as*, or "portions;" and the *S'ánkháyana*, or *Kaushítaki-Brâhman'a*, containing 30 *Adhyáyas*, also subdivided into a number of *Khan'd'as*. The following specimens, selected from the former, may illustrate the manner in which works of this category enjoin sacrificial rites and explain their secret meaning. The first relates to the ceremony of carrying the Soma (q.v.). "The king Soma lived among the Gandharvas. The gods and R'ishis deliberated as to how the king might be induced to return to them. *Vách*, the goddess of speech, said: "The Gandharvas lust after women. I (therefore) shall transform myself into a woman, and then you sell me to them (in exchange for Soma)." The gods answered: "No! how may we live without thee?" She said: "Sell me unto them; if you should want me, I shall return to you." Thus they did. In the disguise of a big naked woman, she was sold (by the gods to the Gandharvas) in exchange for Soma. In imitation (of this precedent), men drive away an immaculate cow of one year's age, this being the price at which they purchase the king Soma. This cow may, however, be rebought; for *Vách* returned to the gods. Hence the Mantras, after Soma has been bought, are to be repeated with a low voice. After Soma has been bought, the goddess of speech is with the Gandharvas; but she returns as soon as the ceremony of carrying the sacred fire is performed."

The following are the speculations of this Brahman'a on the *Yûpa*, or sacrifical post, and the meaning of the sacrificial animal:

"(The theologians) argue the question: Is the *Yúpa* to remain standing (before the fire); or is it to be thrown (into the fire)? (They answer:) For him who desires cattle, it may remain standing. (About this, the following legend is reported.) Once upon a time, cattle did not stand still to be taken by the gods for food. After having run away, the cattle stood still, and, turning toward the gods, said repeatedly: "You shall not obtain us. No, no!" Thereupon the gods saw that *Yúpa*-weapon which they erected. Thus they frightened the animals, which then returned to them. That is the reason that, up to this day, the sacrificial animals are turned toward the *Yúpa* (their head being bent toward the sacrificial post to which they are tied). Then they stood still to be taken by the gods for their food. . . . . The man who is initiated (into the sacrificial mysteries) offers himself to all deities. Agni represents all deities, and Soma represents all deities. When the sacrificer offers the animal to Agni and Soma, he releases himself from being offered to all deities. Some say: 'The animal to be offered to Agni and Soma must be of two colors, because it belongs to two deities.' But this precept should not be attended to. A fat animal is to be sacrificed, because animals (compared to the sacrificer) are fat, and he (compared to them) is lean. When the animal is fat, the sacrificer thrives through its marrow. Some say: 'Do not eat of the animal offered to Agni and Soma. Who eats of this animal, eats human flesh, because the sacrificer releases himself (from being sacrificed) by means of the animal.' But this precept, too, should

not be attended to. The animal offered to Agni and Soma was an offering to Indra, for Indra slew Vr'itra through Agni and Soma. Both then said to him: 'Thou hast slain Vr'itra through us; let us choose a boon from thee.' 'Choose yourselves,' answered he. But they choose this boon from him; and thus they receive (now as their food) the animal which is sacrificed the day previous to the Soma feast. This is their everlasting portion chosen by them; hence one ought to take pieces of it, and eat them."—See M. Haug's edition and translation of the *Aitareya Brâhman'a* (vol. ii. pp. 59, 78), vols. i., ii. (Bombay, 1863).

The principal object for which the *Sâmaveda* was compiled is the performance of those sacrifices of which the juice of the Soma plant is the chief ingredient; and of such sacrifices the most important is the *Jyotisht'oma*, which consists of seven stages: the Agnisht'oma, Atyagnisht'oma, Ukthya, Shod'as'in, Atirâtra, Aptoryâma, and Vâjapeya; but the performance of the Agnisht'oma alone was considered obligatory for those who wished to derive the chief advantage accruing from the celebration of this grand ceremony; while its other six stages, though adding to the merits of the sacrificer, were deemed voluntary. At the performance of such Soma sacrifices, the verses of the Sâmaveda were intoned; and there are special song-books which teach the proper manner how to chant them. The Sanhitâ of the Sâmaveda is preserved in two recensions: in that of the *Rân'âyanîya*, and probably also the *Kauthuma* school. It consists of two parts: the first, the *Chhandograntha*, also called *Archika*, or *Pûrvârchika*, contains, in the present recension, 585 verses, which are arranged into 59 *Das'ati* or decades, these being divided into *Prapât'hakas*, or chapters, and the latter, again, into *Ardhaprapât'hakas*, or half-chapters. The second portion, called *Staubhika*, or *Uttarágrantha*, or *Uttarârchika*, consists of 1225 verses, distributed over nine *Prapât'hakas*, which, too, are subdivided into *Ardhaprapât'hakas*. And there is this peculiarity in the Uttarâgrantha, that being for the most part arranged according to triplets of verses, the first verse of these triplets is frequently one which also occurs in the Archika portion. It is then called the *Yoni*, or parent verse, because the subsequent two, the *Uttará*, are symbolically its children, since they participate of all the modulations, stoppages, and other modifications which may occur in the chanting of the "parent" verse. These modulations, etc., are taught in the *Gânas*, or song-books mentioned before, two of which, the *Veyagâna* and *Aran'yagâna*, relate to the Archika; and two others, the *Uhagâna* and *Uhyagâna*, to the Staubhika part. The text of the Sâmaveda-Sanhitâ, in the Rân'âyaniya recension, has been edited and translated by Dr. J. Stevenson (Lond. 1842–43), and by Prof. Th. Benfey (Leip., 1848).

The number of *Brâhman'as* relating to this Veda is, by the native authorities, given as eight; and their names are: the *Praud'ha-*, or *Panchavins'a-*, the *Shad'vins'a-*, the *Sâmavidhi-*, or *Sâmavidhâna-*, the *Arsheya-*, the *Devatâdhyâya-*, the *Vans'a-*, the *Sanhitopanishad-Brâhman'a;* and the *Upanishad*, which probably is the *Chhândogya-Upanishad*, and thus is ranked among the Brâhman'as. A later Brâhman'a, probably of modern date, and which is not mentioned by Sâyan'a, is the *Adbhuta-Brâhman'a*. The latter and the *Van'sa Brâhmana* have been edited by Prof. A. Weber; the former in the *Indische Studien*, vol. iv. (Berlin, 1858); the latter in the *Abhandlungen der königlichen Akademie der Wissenschaften zu Berlin* (1858).

The history of the Yajurveda differs in so far from that of the other Vedas, as it is marked by a dissension between its own schools far more important than the differences which separated the schools of each other Veda. It is known by the distinction between a Yajurveda, called the *Black*, and another, called the *White Yajurveda*. Tradition, especially that of the Purân'as, records a legend to account for it. *Vais'ampâyana*, it says, the disciple of Vyâsa, who had received from him the Yajurveda, once having committed an offense, desired his disciples to assist him in the performing of some expiatory act. One of these, however, *Yâjnavalkya*, proposed that he should alone perform the whole rite; upon which, Vais'ampâyana, enraged at what he considered to be the arrogance of Yâjnavalkya, uttered a curse on him, the effect of which was that Yâjnavalkya disgorged all the Yajus texts he had learned from Vais'ampâyana. The other disciples, having meanwhile been transformed into partridges (*tittirî*), picked up these tainted texts, and retained them. Hence these texts are called *Taittirîyas*. But Yâjnavalkya, desirous of obtaining other Yajus texts, devoutly prayed to the sun, and had granted to him his wish—"to possess such texts as were not known to his teacher." And because the sun on that occasion appeared to Yâjnavalkya in the shape of a horse (*vâja*), those who studied these texts were called *Vâjins*. That part of this legend was invented merely to account for the name of the *Taittirîyas*, after whom a Sanhitâ and Brâhman'a of the Black Yajurveda, and for that of the *Vâjasaneyins*, after whom the Sanhitâ of the White Yajurveda is named, is clear enough. Nor is greater faith to be placed on it when it implies that the origin of this dissension ascended to the very oldest period of the Yajurveda; for there is strong reason to assume that the division took place even after the time of the grammarian Pân'ini (q.v.). See Goldstücker's *Pân'ini*, p. 139, ff. But so much in it is consistent with truth—that the Black Yajurveda is the older of the two; that the White Yajurveda contains texts which are not in the Black; and that, compared to the motley character of the former, it looks "white," or orderly. This motley character of the Black Yajurveda, however, arises from the circumstance, that the distinction between a Mantra and Brâhma'na portion is not so clearly established in

it as in the other Vedas; hymns and matter properly belonging to the Brâhman'as there being intermixed. This defect is remedied in the White Yajurveda; and it points, therefore, to a period when the material of the old Yajus was brought into a system consonant with prevalent theories, literary and ritual.

The contents of both divisions of the Yajurveda are similar in many respects. Two of the principal sacrifices of which they treat are the *Dars'apûrn'amâsa*, or the sacrifice to be performed at new and full moon, and the *As'wamedha*, or the horse-sacrifice, at the performance of which 609 animals of various descriptions, domestic and wild, were tied to 21 sacrificial posts. A *Purushamedha*, or man-sacrifice, unknown to the other Vedas, is also mentioned in it; its character, however, is symbolical.

The text of the Black Yajurveda is extant in the recension of two schools—that of *Apastamba*, to which the *Taittirîya Sanhitâ* belongs, and that of *Charaka*. The former, which is in course of publication—the first volume and part of the second having been already published, with the commentary of Mâdhavâchârya (Sâyan'a), by Dr. E. Roer and E. B. Cowell in the *Bibliotheca Indica* (Calcutta, 1860–64)—consists of seven *Kân'd'a*, or books, which comprise 44 *Prapât'haka*, or chapters, subdivided into 651 *Anuvâka*, or sections, and containing 2,198 *Kan'd'ikâs*, or portions.

The *Vâjasaneyi-Sanhitâ*, or the Sanhitâ of the White Yajurveda, exists in the recension of the *Mâdhyandina* and *Kân'va* school. In the former—the text of which, apparently also with the commentary of *Mahîdhara*, has been edited by Prof. A. Weber (Berlin, 1852)—this Sanhitâ has 40 *Adhyâyas*, or books, subdivided into 303 *Anuvâkas*, with 1975 *Kan'd'ikâs*.

The principal Brâhman'a of the Black Yajurveda is the *Taittirîya-Brâhman'a*, which, with the commentary of (Mâdhava) Sâyan'a, is in the course of publication by Baboo Rajendralâla Mitra—the first volume and part of the second having already appeared in print (Calcutta, 1860–65) in the *Bibliotheca Indica*. That of the White Yajurveda is the *S'atapatha-Brâhman'a*, the most complete and systematic of all Brâhman'as. Its text, with a semblance of the commentary of *Sâyan'a*, has been edited by Prof. A. Weber (Berlin, 1855).

The Atharvaveda has no circle of sacrifices assigned to it. Its object is, as observed before, to teach how to appease, to bless, to curse, etc. "The most prominent characteristic feature of this Veda," Prof. Whitney, one of its editors, remarks, "is the multitude of incantations which it contains; these are pronounced either by the person who is himself to be benefited, or, more often, by the sorcerer for him, and are directed to the procuring of the greatest variety of desirable ends. Most frequently, perhaps, long life, or recovery from grievous sickness, is the object sought; then a talisman, such as a necklace, is sometimes given, or, in very numerous cases, some plant endowed with marvelous virtues is to be the immediate external means of the cure; further, the attainment of wealth or power is aimed at, the downfall of enemies, increase in love or in play, the removal of petty pests, and so on, even down to the growth of hair on a bald pate."—*Journal of the American Oriental Society*, vol. iii. p. 308. It has been surmised (Müller's *Ancient Sanscrit Literature*, p. 447, ff.) that the hymns of the Atharvaveda "formed an additional part of the sacrifice from a very early time, and that they were chiefly intended to counteract the influence of any untoward event that might happen during the sacrifice." This is possible; but the great importance which the adherents of this Veda themselves attach to it, is founded on other considerations than these. They argue, as appears from the treatise *Atharvan'arahasya*, mentioned above, that the three other Vedas enable a man to fulfill the *dharma*, or religious law, but that the Atharva helps him to attain *moksha*, or eternal bliss. This doctrine is laid down, for instance, in the *Châlika Upanishad* of this Veda, when it says: "Those Brâhmans and others who know the science of the (neuter) Brâhman contained in the *Brahmaveda*, become merged in Brâhman; and it is likewise inferred from other passages in the *S'aunaka-Brâhman'a*. The name of *Brahmaveda* itself, by which this Veda is also frequently called, is, therefore, explained by them, not as implying the Veda which belongs to the province of the priest Brahman, but the Veda which contains the mysterious doctrine of Brahman, the supreme spirit, into which the human soul becomes finally absorbed. It is probable, therefore, that the very uselessness of the Atharvaveda for sacrificial purposes, and the reluctance which was felt to base its sanctity merely on its incantations and spells, invested it in the mind of its followers, with a spiritual character, which was then fully developed in the numerous Upanishads (q.v.) now connected with it.

The text of the Atharvaveda is preserved only in the *S'aunaka* school. Its Sanhitâ consists in the present edition of it, of 20 *Kân'd'as*, or books. Of these, the first 18 are subdivided into 34 *Prapât'hakas*, or chapters, with, altogether, 94 *Anuvâkas*, or sections, each containing a number of *mantras* (the 17th Kân'd'a consisting of a single Prapât'haka). The 19th Kân'd'a is not divided into Prapât'hakas, but into *Anuvâkas*, of which it contains seven; and the 20th likewise divided into *Anuvakas*, has nine, of which the third is subdivided into three *Paryâyas*.—The text of this Sanhitâ has been edited by Profs. R. Roth and W. D. Whitney (Berlin, 1856).

The only existing Brâhman'a of this Veda is the *S'aunhaka-* or *Gopatha-Brâhman'a*. "That this Brâhman'a," Prof. Müller observes, "was composed after the schism of the Charakas and Vâjasaneyins, and after the completion of the Vâjasaneyi-Sanhitâ, may be gathered from the fact, that where the first lines of the other Vedas are quoted in the

Gopatha, the first line of the Yajurveda is taken from the Vâjasaneyins, and not from the Taittiriyas."—*Ancient Sanscrit Lit.*, p. 452. Each of these Vedas received in time *Anukraman'îs*, or indices, which give the first word of each hymn, the number of verse's the names of the deities, the name and family of the poets, and the meter of every verse. The principal treatise of this kind is the *Sarvânukraman'î*, or "The General Index," ascribed to the authorship of *S'aunaka*. For the theosophical works which grew out of these Vedas, see the article UPANISHAD; and for the works which were composed in order to secure a correct reading and understanding of the Vedic texts, and a correct performing of sacrificial acts, see the article VEDÂNGA.—At a later period the name of Veda was also bestowed on *Itihâsas*—legends or legendary works—and *Purân'as* (q.v.), collectively; but in this sense it never obtained real currency. *Upavedas*, or minor Vedas, are also mentioned in the *Charan'avyûha* and other works, and explained by them in the following manner: The Upaveda of the R'igveda, they say, is the *Ayurveda*, or the Veda on medicine—probably the well-known works of Charaka and Sus'ruta; the Upaveda of the Yajurveda is the *Dhanurveda*, or the Veda on archery; the Upaveda of the Sâmaveda is the *Gândharvaveda*, on music; and the Upaveda of the Atharvaveda is the *S'ilpas'âstra*, a work on mechanical arts, or, according to others, the *Arthas'âstras*, works on practical subjects, comprising polity, mechanical science, the training of elephants and horses, and fencing.

In the preceding brief outline of the four Vedas, the question as to the date at which they were composed has not been raised, because, in the present condition of Vedic philology, an answer to it could only be hypothetical. From astronomical facts, based on a statement in a Vaidik calendar, Colebrooke concluded that this calendar was written in the 14th c. before the Christian era (*Miscell. Essays*, vol. i. pp. 109, 110); and though subsequent writers have questioned the full correctness of this conclusion, those most reliable nevertheless admit that the error, if any, could not lessen the antiquity of this calendar by more than 100 or 200 years. As this calendar must have been composed after the R'igveda had been arranged, and as such an arrangement itself must be posterior to the date of its last hymn, a full scope is left for imagination to fill up these intervals. But let it be understood that imagination alone would have to perform this task, since scientific research has as yet not yielded any means to check it, or prompt it on, as the case may be; nor is there any real prospect that future discoveries in Sanskrit literature will supply this want. A safer basis, however, may be looked for, if future research restricted itself to the question as to the *relative* age of these Vedic writings. Much valuable evidence has been already brought forward in this respect to prove that there are R'ishis ancient, and less ancient (see, for instance, J. Muir's *Original Sanskrit Texts*, vol. ii. p. 205, ff.); that there are R'igveda hymns older than others (for instance, in Müller's *Ancient Sanskrit Literature*); but, on the other hand, much confusion has also been produced by starting a theory that all the Brâhman'as belong to one period, and all the hymns to another period preceding it, of which, again, two stages were thought to be discernible, and by assigning dates to the Brâhman'a period, as well as to each of the two stages of the Mantra period. For, apart from the purely imaginary value of such dates, and apart from the circumstance that no evidence whatever has as yet been brought forward to justify an assumption of only two stages of hymns, each of which would comprise only 200 years, it is clear that the similarity of subject-matter alone—such as it marks the literary character of the Brâhman'as—cannot be a criterion for determining that *all* the Brâhman'as must be more recent than *all* the Sanhitâs. That a Brâhman'a of the R'igveda must be posterior to those hymns of the R'igveda Sanhitâ which it mentions, but to those alone—again, that a Brâhman'a of the Sâmaveda must be younger than the hymns of the Sâmaveda on which it relies, and so on—cannot be matter of doubt; but as the Sanhitâ of the Sâmaveda, for instance, must be more recent than that of the R'igveda, and as no fact whatever has been adduced to show why the Aitareya Brâhman'a, or other Brâhman'as of the R'igveda, could not have appeared before a Sâmaveda-Sanhitâ was made, and so forth in the case of the other Vedas, it follows that it would be entirely unsafe to infer that all the Brâhman'as must be more recent than all the Sanhitâs; nay, even that all the Brâhman'as must be later than *all* the hymns of the R'igveda, since not all of them need have existed before the oldest Brâhman'a of this Veda was composed. A result like this is, unhappily, purely negative, but it may have the advantage of counseling caution and stimulating research.

VEDANGA—from Veda (q.v.) and *anga*, limb; hence, literally, "the limb of (the body of) the Veda"—is the name of six Sanskrit works, the object of which is to teach how to read and understand correctly the Vedic texts, and how to apply them correctly to sacrificial purposes. Whether the number of these works was originally the same as it now is, and already was at the time of the Upanishads, may be doubtful. Tradition mentions the following Vedângas: 1 *S'ikshâ*, or the science of proper pronunciation. It is represented by a short treatise of 35, or, in another recension, of 59 verses, which explains the nature of letters, accent, and pronunciation, and is ascribed to *Pân'ini* (q.v.). 2. *Chhandas*, or (a work on) meter, which is ascribed to *Pingala*. 3. *Vyâkaran'a*, or grammar, by which native authorities understand the celebrated work of *Pân'ini* (q.v.); but never those short books, especially concerned in Vedic peculiarities, called *Prâtis'âkhyas*, the existing representatives of which, in all probability, are posterior to Pân'ini (see Gold-

stücker's *Pân'ini*, etc., p. 183, ff.). 4. *Nirukta* (q.v.) 5. *Jyotisha*, or astronomy. "Its chief object is to convey such knowledge of the heavenly bodies as is necessary for fixing the days and hours of the Vedic sacrifices." 6. *Kalpa*, or works on the Vedic ceremonial, which systematize the ritual taught by the Brâhman'a portion of the Veda, omitting, however, all legendary or mystical detail. They are composed in the Sûtra style. See SÛTRA. The Kalpa, or Sranta, Sûtras belonging to the R'igveda are the *As'valâyana-*, *Sânkhâyana*, and *S'aunaka Sûtras;* those relating to the Sâmaveda, the *Mas'aka-*, *Lâtyâyana-*, and *Drâhyâyan'a* Sûtras; those of the Black Yajuveda, the *Apastamba-*, *Baudhâyana-*, *Satyâshâd'ha-*, *Hiran'yakes'in-*, *Mânava-*, *Bhâradvâja-*, *Vâdhûna-*, *Vaikhânasa-*, *Laugâkshi-*, *Maitra-*, *Kat'ha-*, and *Vârâha* Sûtras. The White Yajurveda has only one Kalpa, or 'Sranta, Sûtra connected with it, the *Kâtyâyana* Sûtra, and the Atharveda likewise only one, the *Kus'ika Sûtra.*—At a later period these works were supplemented by a similar class of works, which, however, merely describe the domestic ceremonies, viz., "the marriage rite, the rites to be performed at the conception of a child, at various periods before his birth, at the time of his birth, the ceremony of naming the child, of carrying him out to see the sun, of feeding him, of cutting his hair, and lastly, of investing him as a student, and handing him to a guru, under whose care he is to study the sacred writings." Works of this kind are called *Gr'ihya-Sûtras* (from *gr'iha*, house), and to these, again, were added the *Sâmayâchârika-Sûtras* (from *samayâchâra*, conventional practice), which treat of customs sanctioned by the practice of pious men, but not enjoined or expressly stated in the Gr'ihya-Sûtras. The two last classes of Sûtras, which are not comprised amongst the Kalpa works, then grew into the *Dharmas'âstras*, or law-books, of which that of *Manu* is the chief representative. See Müller's *Ancient Sanskrit Literature*, p. 108, ff.

VEDÂNTA (from the Sanskrit *veda* and *anta*, end; hence, literally, "the end or ultimate aim of the Vedas") is the second great division of the *Mîmânsâ* (q.v.) school of Hindu philosophy. It is chiefly concerned in the investigation of *Brahman* (neuter), or the Supreme Spirit, and the relation in which the universe, and especially the human soul, stands to it; and in contradistinction from the *Pûrvamîmânsa*, or the investigation (*mîmânsâ*) of the former (*pûrva*) part of the Vedas—viz., the Sanhitâ, and especially the *Brâhman'as* (see VEDA)—which contain the *dharma*, or religious law (see MÎMÂNSÂ), it is also called *Uttara-mîmânsâ*, or the investigation (*mîmânsâ*) of the latter (*uttara*) part of the Vedas—viz., *Aran'yakas* and *Upanishads* (q.v.), which treat of (the neuter) *Brahman*, or the Supreme Spirit [not to be confounded with (the masculine) *Brahman*, or the god of the mythological *Trimûrti* (q.v.)]. Sometimes the name given to it is *S'ârîraka-mîmânsâ*, or the investigation of the soul (s'ârîaka). In its method, the Vedânta differs from the Nyâya (see NYÂYA and VAIS'ESHIKA) by endeavoring to explain the universe as a successive development from one ultimate source or principle—whereas the Nyâya, in both its divisions, treats of the objects of human knowledge of which the universe is composed, under different topics, unconcerned about their mutual relation of effect and cause; and from the *Sânkhya* (see SÂNKHYA and YOGA), it is distinct, inasmuch as that system is based on the assumption of a duality of principles whence the universe derives its origin.

The object-matter of the Vedânta is the proof that the universe emanates in a successive development from a Supreme Spirit or soul, which is called *Brahman*, or *paramâtman;* that the human soul is therefore identical in origin with Brahman; that the worldly existence of the human soul is merely the result of its ignorance of this sameness between itself and the Supreme Spirit; and that its final liberation or freedom from transmigration (q.v.) is attained by a removal of this ignorance, that is, by a proper understanding of the truth of the Vedânta doctrine.

According to this doctrine, *Brahman* (neuter) is both the efficient and material cause of the world, creator and creation, doer and deed. It is one, self-existent, supreme, as truth, wisdom, intelligence, and happiness; devoid of the three qualities, in the sense in which created beings possess them; and at the consummation of all things, the whole universe is resolved or absorbed into it. From Brahman individual souls emanate, as innumerable sparks issue from a blazing fire. The soul, therefore, is neither born, nor does it die; it is of divine substance, and as such, infinite, immortal, intelligent, sentient, true. Its separate existence, as distinct from Brahman, is the cause of its ignorance; and this ignorance, which consists in regarding the world as a reality capable of subsisting without Brahman, has a double power—that of enveloping and projecting. By means of the former it makes the soul liable to mundane vicissitudes, as to the sensations of pleasure, pain, etc. The projective power of ignorance, when encompassing the soul in its fourth condition, or that of pure intellect (its other conditions are: waking, dreaming, and dreamless sleep) produces out of the darkness which then prevails the five subtile elements—viz., *ether*, which is the substratum of the quality sound; *air*, which arises from ether, the substratum of touch; from air, *fire or light*, the substratum of color; from light, *water*, the substratum of savor; and from water, *earth*, the substratum of smell. From these subtile elements are then produced 17 subtile bodies and the five gross elements. The former, also called *lingas'arîra*, because they are bodies (*s'arîra*) which impart to existing beings their individual character (*linga*), are *the five organs of perception*—viz., the organs of hearing, touch, sight, taste, and smell, which arise sev-

erally from the *pure* or inactive particles of each of the subtile elements; further, *two intellectual organs*, which are produced from the *mingled pure*, or inactive particles of the subtile elements—viz., *buddhi*, understanding, the function of which is to arrive at a certainty or conclusion, and *manas* (an organ of volition and imagination), the function of which consists in willing and doubting—thinking and referring the external objects to one's own self, being two functions common to both of them; lastly, *the five organs of action*—viz., the voice, the hands, the feet, the organ of excretion and that of generation, which are severally produced from the *foul* or *active* particles of each of the subtile elements; and *the five vital airs*, which are produced from the *mingled foul* or *active* particles of the subtile elements—viz., the air breathed forth, which has its place in the fore-part of the nose; the air breathed downward, which has its place in the lower intestines; the air which circulates through the whole body; the ascending air, which has its place in the throat, and the descending air in the middle of the body, which causes assimilation and digestion of food, produces semen, excrements, etc. (Later Vedântists assume ten such vital airs—viz., besides the foregoing, the airs which severally cause retching, winking, hunger, yawning, and fattening.) The five *gross elements* are the five subtile elements, when, according to a theory derived from a scriptural text, they have become so divided and combined that each of them retains a preponderating portion of itself, and consequently of the quality of which it is the substratum—as ether of sound, etc.—and besides smaller portions of the other subtile elements, and the qualities of which they are the substrata. From these gross elements then arise the various (mythological) worlds, and this world, too, with bodies which are distinguished as viviparous, or those produced from a womb, as men, beasts, etc.; oviparous, or those produced from an egg, as birds, snakes, etc.; those generated by "sweat" or hot moisture, as lice, gnats, etc.; and those germinating, as creepers, trees, etc. The soul, when existing in the body, is encased in a succession of "sheaths." The first or interior "sheath" consists of *buddhi*, associated with the organs of perception; the second, of *manas*, associated with the organs of action; and the third, of the vital airs together with the organs of action. These three "sheaths" constitute the subtile body of the soul, which attends the soul in its transmigrations; and the collective totality of such subtile bodies is the supreme soul, as regarded in its relation to the world; when it is also called "the soul which is the thread," or passes like the thread through the universe, or hiran'yagarbha, or life. The fourth and exterior "sheath" of the soul is composed of the gross elements; and the collective aggregate of such gross bodies is the gross body of the deity. This whole development being the result of ignorance, the soul frees itself from its error by understanding that the different stages in which this development appears, do not represent real or absolute truth; and when its error has completely vanished it ceases to be re-born, and becomes reunited with Brahman, whence it emanated. But since the means of arriving at a final deliverance can only be the complete mastery of the truths of the Vedânta, other means, such as the performance of sacrifices or other religious acts enjoined by the Vedas (q.v.), or the practice of Yoga (q.v.), cannot lead to the same result. They may be meritorious, and are even recommended as such, but can effect only an apparent liberation. Of this there are two kinds: one liberation which is effected in lifetime, and enables a man to perform supernatural actions or wonders, as the evocation of the shades of progenitors, going anywhere at will, and similar feats; and another which takes place after death, and enables the soul, not divested of its subtile body, to reside in heaven; but after a time its effect ceases, and the soul has to renew its mundane existence. In order to fit the mind for meditating on these truths, various moral duties are enjoined, and various practices are recommended, especially by later Vedânta writers. Thus, the student of the Vedânta is told not to hurt a sentient being, to speak the truth, not to steal, to practice continence, and not to accept gifts; to remain pure and content, to do penance, and to study the Vedas; also to remain in certain postures, to practice various modes of suppressing his breath, and the like. These injunctions, however, are extraneous to the doctrine itself, and appear to be a compromise with the old orthodox faith, which requires the peformance of religious acts, and a later stage of it, which favors such austere practices as are especially known by the name of Yoga (q.v.). Tho doctrine of *bhakti*, or faith, does not belong to the older Vedânta; it is, however, an interesting feature of the later periods of this philosophy; and the same observation applies to the doctrine of *Máyá*, or illusion, according to which the world has no reality whatever, but is merely the product of imagination; for the older Vedânta, as will have been seen, merely teaches that the world is not *the truth*, but does not deny its material reality.

The oldest work on this philosophy is attributed to *Bâdaráyan'a*, or *Vyâsa* (q.v.), and is written in the Sûtra (q.v.) style; it is called the *Brahma-Sûtra;* it consists of four *adhyâyas*, or lectures, each subdivided into four *pâdas*, or chapters; each pâda containing a number of Sûtras. The number of the latter is 558, and that of the *adhikaran'as* or topics treated in them, 191. The most important commentary on this work is the *S'ârîrakamîmânsâ-bhâshya*, by *S'ankarâchârya* (q.v.); and this commentary, again, has been commented on by a great variety of writers. The text of the Sûtras and this commentary have been edited at Calc., 1818; and the text with this commentary, and a gloss on the latter, by Govindânanda, in the *Bibliotheca Indica*, by Pandita Râma Nârâyan'a Vidyâratna, Calc., 1863. Of the great number of other commentaries on the

Brahma-Sûtras, mention may be made only of that by *Râmânuja* (q.v., under VAISHNAVAS), and of a short but very lucid one, by *Anûpanârâyan'as'iroman'ibhat't'a* (edited at Calc., without date). Among elementary treatises on the Vedânta, the most popular is the *Vedântasâra*, by *Sadânanda*, which, with the commentary of *Râmakr'ishn'a Tîrtha*, has been edited at Calc., 1829, and with this and another commentary by *Nr'isinhasaraswatî*, at Calc., 1849. It has been edited and translated also by the late Dr. J. R. Ballantyne (*A Lecture on the Vedânta, embracing the Text of the Vedânta Sâra*, Allahabad, 1850), who also translated the beginning of the Brahma-Sûtras.—A very useful compendium of the *Adhikaran'as*, or topics, is the *Adhikaran'amâlâ*, by *Bhâratîtîrtha*, which, with the commentaryof *S'rî Anandachandra-Vedântavâgîs'a*, has been edited, Calc., 1862, and as an appendix to the Brahma-Sûtras, with extracts from this commentary, in the *Bibliotheca Indica*, 1863.

VEDDER, ELIHU, painter; b. in New York, Feb. 26, 1836; studied with Picot in Paris; and after 1856 lived almost continuously in Rome, Italy. He was elected a national academician 1865, and member of the society of American artists 1880, and was honorably mentioned at the Paris exposition 1889. His paintings include "The Lair of the Sea Serpent;" "The Arab Listening to the Sphinx;" "Young Marsyas;" "Cumœan Sibyl;" and a series of mural paintings in the new congressional library at Washington. His illustrations of the Rubaiyat of Omar Khayyám attracted much attention.

VEDETTES are mounted sentinels, placed about 100 yards in advance of the outposts of an army, to watch the enemy and signal the approach of danger.

VEER, in sailing, is to pass from one board to the other by bringing the stern to windward. It is therefore the same action as *gybing* (q.v.).

VEGA, GARCILASO DE LA. See GARCILASO DE LA VEGA.

VEGA-CARPIO, LOPE FELIX DE, a celebrated Spanish poet, was born at Madrid on the 25th November, 1562. From his very infancy, he is said to have given promise of extraordinary talent. Like Pope, he "lisped in numbers." On the death of his father, the family, originally a good one, fell into great difficulties, and was broken up. The young Lope fell to the charge of his uncle, the inquisitor, Miguel del Carpio, who spared no pains to give him a good education. He was sent to the imperial college at Madrid, and seemed to be progressing quietly toward the holy state, to which, by his uncle, he was destined, when an odd whim struck the lad, and, being then fourteen, he went off on a roving expetition with a comrade. But he and his companion were speedily arrested as thieves on their trying to effect the sale of a chain of gold (probably stolen from Lope's uncle), and sent back to Madrid. The returning prodigal was but coolly received by his reverend relative, who declined to further concern himself with a nephew of such distinctly *lay* propensities. He in consequence became a soldier; and in 1577 served at Terceira against the Portuguese. After this we find him taken in hand by Geronimo Manrique, bishop of Avila, who sent him to finish his studies at the university of Alcala. Here he was again ripening for holy orders, and was nearly in fact ripe, when again the passion of the vagabond drove him out upon the world a pervert. For some time, at this period of his life, Lope disappears from public view; and probably his adventures were of the kind which a discreet biographer will always permit his hero to prosecute as far as possible in private. It is understood that in his dramatic romance, *Dorothea*, he afterward favored the world with a sketch of himself and of these his early experiences; and if this is in detail to be taken as history, Lope, on his own shewing, must have been no more a model of propriety than certain other great poets who might be named. Toward 1585 we find him again at Madrid, attached to the person of a young duke of Alva, for whom he composed the piece entitled *Arcadia*, a tedious pastoral, with verses interspersed, which only in detached passages displays his brilliant ability. About this time he married a lady of condition, by the name of Isabella de Urbino; but his domestic felicity was speedily cut short by a misadventure. Having had some difference with a gentleman of court, he satirized him in a filthy ballad; and on finding that he took it amiss, gave him satisfaction by running him through the body. For this he was thrown into prison, and afterward exiled to Valencia. He returned to Madrid as soon as he could with safety, and soon after lost his wife, whom he is said to have tenderly loved. Grief for her death, complicated with want of success in another of his little love-affairs, drove him to join the famous *Armada*, then being fitted out for the conquest of England. Through the perils of this disastrous expedition Lope came with a whole skin, and in 1590 was again safe in Madrid. A brother to whom he was much attached, and who sailed as an officer in the same vessel, had not the same luck, but died during the voyage. It is a characteristic trait, that Lope—who, whatever else he may be doing, must always be conceived as flooding out continuous torrents of verse—composed, amid the distractions of tempest and battle, a long poem, the *Hermosura de Angelica*, which, as a continuation of the *Orlando Furioso* of Ariosto, has found favor even with express admirers of that poet. Shortly after his return he became secretary to the marquis of Malpica and subsequently to the count of Lemos, whose service he quitted soon after his marriage, in 1597 to Donna Juana de Guardio, resolving thenceforward to trust solely to literature for his livelihood. This he could well do with every confidence, as already one of the most admired authors of the day, and by far the most popular dramatist. The years immediately succeeding, he himself frequently afterward refers to as the hap-

piest period of his life; but it was not of very long duration. At the age of seven, his son Carlos died; and soon after, in giving birth to a daughter, his wife also died. The double blow was severe. A mistress, indeed, remained to console him, Donna Maria de Luxan, by whom he had a boy and girl, the latter of whom, Marcela, was the most beloved of all his children. But he had no doubt got a little tired of Donna Maria; and about this time he began to turn his thoughts seriously to religion. Having had as much vice as he cared for, he considered he had reached the point in his career at which piety might begin to be prosecuted with advantage. Accordingly, after an interval of devout preparation, he became, in 1609, a priest of the order of St. Francis. Of his zeal in his new functions, there is evidence in the fact, that in Jan. 1623, he took prominent part in the ceremony of burning a heretical brother of his order. As to his performance of priestly duty otherwise, strictly thus much is known, that, with his old unremitting assiduity, he continued to pour forth poems and dramas, not always of a clerical or decent kind. During his last years, he fell into a profound religious melancholy. Despite the decay of his strength, he was rigorous in keeping himself up to the severest mark of discipline; in particular, he scourged himself terribly. Finally, in the beginning of Aug. 1635, he gave himself a scourging so terrible, that the walls of the chamber were found bespattered with his blood ; and some days after he died of it. Lope was the idol of his contemporaries ; his very name became a synonym of excellence, and his fame was almost as remarkable outside of Spain. His dramas, on which his popularity mainly rested, number not less than 1800. The ease and grace of his versification are unsurpassed, but in deep and serious qualities he is deficient.

VEGETABLE CHEMISTRY is the chemistry of plants. On submitting to incineration a plant which has been dried at a moderate heat till it ceases to lose weight, we find that the residue, which consists of mineral salts and a little carbon, is much lighter than the original plant, the portion which is burned off, or apparently lost, corresponding to the organic constituents of the plant. Hence every plant, like every animal, is composed of *organic* and *mineral* or *inorganic constituents*. While the mineral constituents of the plant are also found in the crust of the earth, the organic constituents are primarily formed in the plant itself from inorganic matters, viz., from *water*, *atmospheric air*, and the *soil*, which collectively may be termed the food of plants.

(1.) All organic constituents of plants contain *carbon*. (2.) All such organic constituents contain *hydrogen*. Some, as, for example, many ethereal or volatile oils, consist solely of these two elements. (3.) The greater proportion of these compounds contain *oxygen* in addition to the two preceding elements. To this class belong those constituents of plants which are at the same time of the most general diffusion and of the greatest physiological and economic importance; namely, the so-called *carbo-hydrates*, which consist of carbon combined with hydrogen and oxygen in the exact proportion in which the last two elements form water. Under this title are included cellulose, starch, gum, etc. Other organic constituents contain not only carbon with hydrogen and oxygen in the above ratio, but an excess of hydrogen. In this category may be placed almost all the *organic acids*, many *ethereal oils*, *wax*, the *resins*, many of the so-called *glycosides*, and the *fats*. (4.) With the above elements, *nitrogen* is associated, to form two very important groups of constituents, viz., the *organic bases* or *alkaloids*, and the *albuminates* or *proteine bodies*. Although the nitrogenous groups never form more than a small part of the mass of a plant, nitrogen is never altogether absent from a plant. (5.) In association with all the above-named elements, *sulphur* in small quantity is present in the albuminates of all plants; in association only with carbon and hydrogen, it occurs in oil of garlic and oil of asafetida; and when combined with carbon, hydrogen, and nitrogen, it has been as yet only found in oil of mustard. Whether *phosphorus* in very minute quantity occurs in any of the vegetable albuminates, is still uncertain.

The inorganic constituents which are found in the ashes of all plants are: *potash*, *soda*, *magnesia*, and *lime*, in combination with *phosphoric*, *sulphuric*, *hydrochloric*, and *carbonic acids*, and additionally, *iron*, *manganese*, and *silica*, with traces of *fluorine;* while the marine plants or sea-weeds contain also appreciable quantities of *bromine* and *iodine*. *Alumina* and *baryta* are also occasionally found, as also are *nitrates* in certain plants. The carbonates almost always found in the ash are, as is well known, for the most part formed by the action of the incineration upon the salts of the vegetable acids, such as the acetates, citrates, etc., and probably in some other respects, the arrangements of the constituents of the ash are not precisely identical with those of the mineral ingredients while existing in the actual plant. Among the most essential of the inorganic constituents is *water*, which acts as a solvent for the matters dissolved in the vegetable juices, and forms a very preponderating part of the mass, sometimes amounting to from 86 to 96 per cent. of the whole plant. From the preceding remarks, it is obvious that the nutrition and development of plants is dependent on their absorbing *carbon-compounds*, *hydrogen-compounds*, *nitrogen-compounds*, *sulphur-compounds*, *water*, and such *inorganic compounds* as yield the necessary inorganic constituents in a form capable of assimilation; together with the presence of *oxygen*, which is required for the formation of organic oxygenous compounds.

The assimilation of *carbon* first claims our attention. The composition of the atmospheric air, from whatever part of the earth's surface it is taken, is, as is well known, constant, in so far as the relative volumes of oxygen and nitrogen are concerned; while

the variations in the carbonic acid, except when there are obvious causes for an excess (as, for example, an over-crowded room), are very slight, and, as a general rule, deviate scarcely at all from 4 volumes in 10,000 of air. Yet causes disturbing this uniformity are perpetually at work. Prof. Mulder, adopting Lavoisier's and Davy's experiments, according to which a man consumes about 26 cubic ft. of oxygen in 24 hours (and later observers place the daily quantity at 45 cubic ft.), calculated his yearly consumption at more than 9,500 feet. Considering the enormous numbers of men and animals on the surface of the globe, and the lamps, fires, furnaces, etc., ever burning, the atmosphere would apparently soon cease to be fit for the support of life (1) in consequence of the great diminution of oxygen, a gas essential to life, and (2) in consequence of the great excess of carbonic acid, a gas deleterious to life. The cause of this marvelous uniformity of atmospheric air under these circumstances is that function of plants by which they absorb their carbon. It is to the experiments and observations of Priestley in 1771, Ingenhousz in 1776, Senebier in 1807, and many later observers, that we are indebted for the knowledge of the great general fact, that plants take up the carbonic acid from the air, reduce it in their organism, and retain the carbon for the composition of their own organisms, while they restore the oxygen gas to the atmosphere. It is chiefly by the leaves, which may be regarded as the respiratory organs, that this process is carried on. It is needless here to notice the questions as to whether it is only during light, or constantly, that these changes go on; whether different rays of the spectrum act with more or less power in liberating the oxygen, etc. Independently of the proof afforded, for example, by placing green plants in a mixture of 70 parts of common air and 30 parts of carbonic acid, and finding that, in the course of four hours, the carbonic acid has been almost entirely replaced by oxygen, we have obvious evidence in the case of lichens growing on a naked rock, that the carbon which they contain must be obtained from the atmosphere. In the case of aquatic plants, the process is identical, the atmospheric air being dissolved in the water. Carbon, in some form of combination or other, probably forms about two-thirds of the weight of a dried plant. The assimilation of *hydrogen* from the decomposition of water in and by the plant, is not capable of the same direct proof as that of carbon; but there are strong grounds for believing in its occurrence. This view is supported by the composition of wax, the resins, volatile oils, etc., and indeed it is difficult to see from what other source the hydrogen could be derived. In that case, the water, like the carbonic acid, contributes its oxygen to the air. The *nitrogen*, which enters into certain constituents of plants, is derived from ammonia, and not, as might have been supposed, directly from the air, of the volume of which it forms about four-fifths. It has been shown by the direct observations of Boussingault, that plants cannot assimilate nitrogen, that those which have been made to absorb it by placing their roots in nitrogenous water, throw it off unchanged, and that vegetation cannot exist in a soil which contains no substances readily convertible into ammonia. The indifference of nitrogen to other elements, and the extreme readiness with which ammonia becomes decomposed, and enters into different combinations (the amides, imides, amido-acids, compound ammonias, and probably also the albuminates, being derivatives of it), together with the conclusion we draw from the action of liquids containing ammonia, or matter convertible into it, as gas-liquid, fluid sewage, etc., confirm this view. The ammonia taken up by plants is obtained partly from the air, and partly from the soil. In the air it is formed after thunderstorms, and it is further supplied to the atmosphere by putrefactive processes, animal excretions, and volcanic action. It is indeed found in snow and in all rain-water, and is thus conveyed to the soil. Although direct experiments show that the air contained in the pores of the soil is richer in ammonia than ordinary atmospheric air, it is easy to show that a plant can derive its ammonia from the latter alone, by a reference to the vegetation on naked rocks, or by growing plants in powdered charcoal duly moistened with rain-water. Hence both air and soil contribute the ammonia from which the nitrogen is fixed in the plant. The *oxygen* which occurs in the various constituents of the plant is derived from the decomposed carbonic acid and water, and corresponds to the difference between the amount contained in those absorbed compounds and the amount liberated to the atmosphere. The *sulphur* that occurs in the albuminates and certain ethereal oils must be derived from the soil, since it does not occur either free or in combination in the air; and as the only form in which it is found in common soil is as sulphates, plants must have the property of decomposing these salts, and appropriating their sulphur after reduction. Extensive experience has proved that certain *inorganic constituents* are as indispensable to the life and development of the plant as the organic elements we have been considering; and further, that special plants require special inorganic constituents, as is shown in works on agricultural chemistry. The two following facts seem well established: (1) that the roots of plants exert a special selective power, and absorb some salts, and reject others that are also in solution in the water of the soil; and (2) that the top or vegetable soil has the power of absorbing and retaining the most necessary mineral ingredients, and does not allow them to be carried deep into the ground by the rain; but for the discussion of this subject we can only refer to the experimental researches of Liebig, Mulder, Huxtable, Way, etc. It would be altogether out of place to enter into the consideration of the prodigious synthetic and analytic power of the vegetable cells; we shall merely indicate how some of the most important

vegetable compounds are probably formed; beginning with the *vegetable acids*. "Even," says Prof. Gregory, "when carbonic acid and water are brought together in the cell, this is not enough. There must be present, first, albuminous matter, without which no active cell can exist; secondly, mineral matter, especially alkalies, phosphates, and salts. All these conditions being fulfilled, and light being admitted, we may suppose the first organic acid formed to be oxalic acid, the least complex of all."—*Organic Chemistry*, 4th ed. p. 541. Putting it in the briefest terms, the cell separates 1 atom of oxygen from 2 molecules of carbonic acid, and in presence of water yields 1 molecule of *oxalic acid*, or $2CO_2 - O + H_2O = H_2C_2O_4$. Two equivalents of dry oxalic acid, $2H_2C_2O_4$, by taking up 1 molecule of water, and losing 4 atoms of oxygen, yield *malic acid*, $C_4H_6O_5$. *Tartaric* and *citric acids* are capable of a similar production. Thus, 2 equivalents of dry oxalic acid, combining with 1 of water, and losing 3 atoms of oxygen, yield tartaric acid, $C_4H_6O_6$; and similarly, 3 equivalents of dry oxalic acid, combining with 1 of water, and losing 6 atoms of oxygen, yield citric acid, $C_6H_8O_7$. In like manner every vegetable acid, and every one of the neutral compounds of carbon, hydrogen, and oxygen, may be derived from some less complex compound, containing more hydrogen than itself; or, it may be supposed to be derived directly from carbonic acid and water, oxygen being, on every supposition, given off. "As the proportion of oxygen to carbon diminishes, the acids become weaker, till the oxygen exactly suffices to form water with the hydrogen, when we have either very feeble acids, or neutral bodies, such as sugar, gum, and starch. As the oxygen is still further diminished, we have neutral, bitter, and acrid compounds, or colored bodies, or such as yield coloring matters, with ammonia and oxygen; further on still we have aromatic oils, and volatile, quasi-resinous, crystallizable acids; then resins; and lastly, when all the oxygen is expelled, certain oils, which are carbo-hydrogens."—Gregory, *op. cit.*, p. 543. Although each individual substance is doubtless in reality derived from some substance only a little less complicated than itself, the final result, in so far as showing their mode of construction is concerned, is the same as if they were all obtained directly from carbonic acid and water. The following tabular view (compiled by Gregory) will serve to show how all the leading groups of vegetable compounds are produced from carbonic acid and water by deoxidation. Gregory's formulæ are here altered so as to conform to the new system of chemical nomenclature:

SUBSTANCES FORMED. Name.	Formula.	=	Carbonic acid.	+	Water.	—	Oxygen.
1. *Vegetable Acids*—							
Tartaric acid	$C_4H_6O_6$	=	$4CO_2$	+	$3H_2O$	—	5O
Malic acid	$C_4H_6O_5$	=	$4CO_2$	+	$3H_2O$	—	6O
Citric acid	$C_6H_8O_7$	=	$6CO_2$	+	$4H_2O$	—	9O
2. *Carbo-hydrates*—							
Cellulose	$C_6H_{10}O_5$	=	$6CO_2$	+	$5H_2O$	—	12O
Starch	$C_6H_{10}O_5$	=	$6CO_2$	+	$5H_2O$	—	12O
Cane-sugar	$C_{12}H_{22}O_{11}$	=	$12CO_2$	+	$11H_2O$	—	24O
3. *Other Neutral Bodies**—							
Mannite	$C_6H_{14}O_6$	=	$6CO_2$	+	$7H_2O$	—	13O
Salicine	$C_{13}H_{18}O_7$	=	$13CO_2$	+	$9H_2O$	—	28O
Pectine	$C_{28}H_{42}O_{24}$	=	$28CO_2$	+	$21H_2O$	—	53O
Hematoxyline	$C_{16}H_{14}O_6$	=	$16CO_2$	+	$7H_2O$	—	33O
Elaterine	$C_{30}H_{25}O_9$	=	$30CO_2$	+	$12\frac{1}{2}H_2O$	—	$63\frac{1}{2}O$
4. *Oxygenated Volatile Oils, and Allied Acids*—							
Oil of bitter almonds	C_7H_6O	=	$7CO_2$	+	$3H_2O$	—	16O
Benzoic acid	$C_7H_6O_2$	=	$7CO_2$	+	$3H_2O$	—	15O
Oil of cinnamon	C_9H_8O	=	$9CO_2$	+	$4H_2O$	—	21O
Cinnamic acid	$C_9H_8O_2$	=	$9CO_2$	+	$4H_2O$	—	20O
5. *Oily and Fatty Acids*—							
Acetic acid	$C_2H_4O_2$	=	$2CO_2$	+	$2H_2O$	—	4O
Butyric acid	$C_4H_8O_2$	=	$4CO_2$	+	$4H_2O$	—	10O
Valerianic acid	$C_5H_{10}O_2$	=	$5CO_2$	+	$5H_2O$	—	13O
Stearic acid	$C_{18}H_{36}O_2$	=	$18CO_2$	+	$18H_2O$	—	52O
6. *Resins and Camphors*—							
Many resins	$C_{10}H_{14}O$	=	$10CO_2$	+	$7H_2O$	—	26O
Camphor	$C_{10}H_{16}O$	=	$10CO_2$	+	$8H_2O$	—	27O
Borneo camphor	$C_{10}H_{18}O$	=	$10CO_2$	+	$9H_2O$	—	28O
7. *Carbo-hydrogens*—							
Oil of lemons	$C_{10}H_{16}$	=	$10CO_2$	+	$8H_2O$	—	28O
Oil of turpentine	$C_{10}H_{16}$	=	$10CO_2$	+	$8H_2O$	—	28O
Oil of juniper	$C_{10}H_{16}$	=	$10CO_2$	+	$8H_2O$	—	28O
Cumole	C_9H_{12}	=	$9CO_2$	+	$6H_2O$	—	24O
Cymole	$C_{10}H_{14}$	=	$10CO_2$	+	$7H_2O$	—	27O

A glance at the composition of these seven groups shows that they present a series of deoxidations, till in the sixth, very little oxygen, and in the last, no oxygen whatever is left. Thus, leaving out of view, for want of space, the compounds in which nitrogen and sulphur enter, "oxalic acid is first formed, and then malic, tartaric, citric, etc., acids from it or from each other; then sugar, starch, etc., from the acids; bitter, acrid, and colored compounds from the sugar, starch, etc.; then oxygenated volatile oils; and then acids perhaps also from sugar, etc.; then the oily and fatty acids, either from the preceding oils and acids, or from sugar; then the resins from the fats, or from sugar; and lastly, the carbo-hydrogens. Thus, we have a picture of the whole process of vegetation

* In this group, which is very numerous, compounds of a most discordant character appear. Of the specimens we have selected, the first closely resembles a sugar; the second is a pure bitter; the third, a gelatinizing substance; the fourth, a pigment, and the fifth, an acrid poison.

as far as concerns compounds devoid of nitrogen and sulphur; and we find it uniformly to be one of deoxidation."—Gregory, *op. cit.*, p. 548. To produce nitrogenous compounds, such as asparagine, amygdaline, nicotine, morphine, caffeine, etc., it is only additionally necessary that ammonia should be present, and the plant by a similar process gives rise to nitrogenous products, the process being shown as below:

Asparagine	$C_4H_8N_2O_3$	=	$4CO_2$	+	H_2O	+	$2NH_3$	—	6O
Amygdaline	$C_{20}H_{27}NO_{11}$	=	$20CO_2$	+	$12H_2O$	+	NH_3	—	41O
Nicotine	$C_{10}H_{14}N_2$	=	$10CO_2$	+	$4H_2O$	+	$2NH_3$	—	24O
Morphine	$C_{17}H_{19}NO_3$	=	$17CO_2$	+	$8H_2O$	+	NH_3	—	39O
Caffeine	$C_8H_{10}N_4O_2$	=	$8CO_2$	—	H_2O	+	$4NH_3$	—	13O

It is easy to show how the sulphur contained in certain oils (oil of garlic, $(C_3H_5)_2S$, for example) is probably obtained by the reduction of the sulphuric acid existing in the sulphates of the soil; but the composition of the albuminates containing both sulphur and nitrogen is so complex that we cannot venture to attempt a popular explanation of the mode of formation of these matters from the simple food of plants. On this subject the reader may consult Liebig's *Agricultural Chemistry*, *Letters on Chemistry*, and *Laws of Husbandry;* Mulder's various works (a new edition of his great work is now being translated, in parts, into German); Rochleder's *Phytochemie*, and the portion of Gregory's *Organic Chemistry*, and of the third volume of Gorup-Besanez's *Handbuch der Chemie*, devoted to this question.

VEGETABLE PHYSIOLOGY. All the most important departments of this subject have been already noticed in this work under the various headings of Circulation of Sap, Flower, Fruit, Leaves, Metamorphosis of Organs, Plant, Root, Seed, Spore, Stem, etc. We shall therefore here only discuss one subject, which has not been separately considered—namely, the organs and functions of reproduction in plants. Although, as we learn from Herodotus, the Babylonians knew that there were male and female date-trees, and that the female required the concurrence of the male to become fertile, and Theophrastus in his work *On the History of Plants*, and other ancient authors, frequently mention the sexes of plants, Cæsalpinus, who died at Rome in 1603, seems to have been the first writer who directed his attention to the reproductive organs of plants; and he speaks vaguely of an emanation from the male causing fertility in the female; and Grew, in 1676, seems to have been the first who distinctly recognized the functions of the stamens and pistils. Ray, in his *Historia Plantarum*, 1694, adopted and enforced Grew's view; and Geoffroy, in 1711, read a memoir before the royal academy supporting the same view. Linnæus, in his *Systema Naturæ* (1748), made these organs the foundation of his system of classification into sexual and non-sexual plants, the former being phanerogamous, or flowering, and the latter cryptogamous, or flowerless; in the latter division of plants, he could not detect stamens or pistils; and it was not till 1782, when Hedwig's work on mosses was published, that anything was known with certainty regarding the sexual organs of any of the cryptogamia. From this brief notice of the early history of this subject, we proceed to the consideration of reproduction in the phanerogamous plants. A complete flower consists, as is well known, of four whorls (*verticils*), placed alternately within one another, the two internal being the *stamens* (q.v.) and *pistils* (q.v.), which are the essential organs of reproduction; while the two external are the *calyx* and *corolla*, which constitute the floral envelopes or protective coverings.

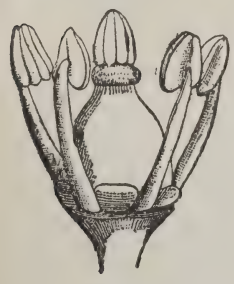

Fig. 1.

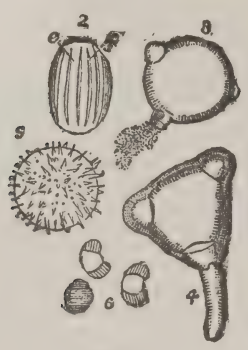
Androecium and gymnœcium (or, in other words, the stamens and pistil) of the vine, with the disk surrounding the base of the ovary.

Both the stamens and the pistils originate, like the floral envelopes (see Flower), from the thalamus, or upper part of the axis or peduncle, in the form of minute cellular processes; and in their development they resemble leaves, although in their appearance, they are less like leaves than are the floral envelopes. These parts are well seen in the accompanying diagram (fig. 1) of the flower of the vine, after it has cast its petals. There are here five stamens (the filament of one being concealed by the pistil), with introrse* two-lobed anthers. As separate articles are devoted to Stamens and Pistils, it is unnecessary to enter into any details regarding their anatomical structure. A few additional remarks on the pollen are, however, called for. This (the male fertilizing agent) consists of cells contained in the anther case, and is discharged by various kinds of longitudinal, transverse, valvular, or porous dehiscence. When examined by the naked eye, it usually appears as a yellow powder; but when magnified, it is found to consist of cellules of different singular forms, varying in size from $\frac{1}{300}$ to $\frac{1}{700}$ of an inch in diameter. Oval, spherical, and triangular forms of pollen are shown in figs. 2 to 6; and they may be square cylindrical hour-glass shaped, etc. These pollen-grains are developed in the large cells in the early stage of the anther. The contents of each cell

* This term is applied to anthers which open on the side next the pistil.

divide first into two, and afterward into four parts, each of which becomes covered with cellulose, so as to constitute independent cells or grains. These grains either burst through the parent cell, and become liberated, or they remain united in fours or some multiple of four, as in many species of acacia; or, in large masses, such as those seen in orchids and in asclepias, when they constitute *pollinia*. Each pollen-grain has usually two coverings: the outer one, called *extine*, being a firm membrane, often marked with bands or rough points; and the inner one called *intine*, which is thin, and capable of extension. In the interior of the pollen-grains, a minute granular matter exists, called *fovilla*—the granules, which are mixed with starch and oil, varying from $\frac{1}{4000}$ to $\frac{1}{30000}$ of an inch in diameter. On moistening pollen-grains in water, they swell till the intine bursts at one or more points, and expels the fovilla. In the act of impregnation the pollen is scattered on the pistil, and is moistened on one side by the fluid of the stigma (a part of the pistil composed of loose cells, which secrete a viscid fluid, and are uncovered by epidermis). It is then observed that the intine, instead of bursting, protrudes in the form of a tube called the *pollen-tube*. The number of these tubes varies greatly in different plants. According to Amici (as quoted by Balfour, to whose useful *Class-book* we are indebted for most of our facts and illustrations), the two pollinia of *orchis morio* contain each about 200 secondary small masses, composed of grains united in fours, and each of these small masses presents 300 openings capable of emitting tubes. In order that an embryo plant



FIGS. 2 to 6.

Fig. 2.—Elliptical pollen of milkwort (*polygala*), viewed lengthwise. Its surface, or extine, *e*, is marked with grooves or slits, *f*, where the intine protrudes. Fig. 3.—Ripe round pollen of cherry (*cerasus*) discharging its fovilla through a tubular opening formed by the intine. There are two other points at which the intine is seen protruding. Fig. 4.—Triangular pollen of evening primrose (*œnothera*), with one pollen tube protruding. This tube is formed by the intine, which is also seen projecting at the other angles. Fig. 5.—Round ripe pollen of hollyhock (*alcea*), with its extine, covered with prominent points. Fig. 6.—Pollen of fir (*pinus*), in which, by the increase of the intine, the extine is separated into two hemispherical portions marked by the dark spaces at each end of the grains.

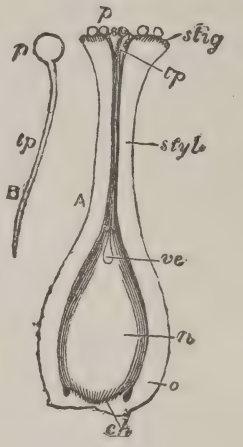


FIG. 7.

Pistil and pollen of polygonum. A, stigma, *stig*, with pollen-grains, *p*, adherent to it, sending tubes, *tp*, down the conducting tissue of the style, *styl;* the ovary, *o*, containing the ovule with its covering and central cellular mass or nucleus, *n*, containing a rudimentary embryo-sac *ve*, in which ultimately the embryo is developed. The base of the ovule attached to the placenta, is marked by the chalaza, *ch*. B, pollen-grain, *p*, separated, with pollen-tube, *tp*.

may be formed, the mature pollen must be discharged from the anther cells of the stamen, and brought into contact with the stigma, through which, and then through the conducting tissue of the style, it must pass until it reaches the foramen, or micropyle, of the ovule. The means by which this contact is accomplished are various, such as elasticity and irritability of the stamens, the action of currents of air, and the intervention of insects passing from the male to the female plant. In the case of the orchids, fertilization is solely effected by the agency of insects. The fertilizing power of pollen is retained for a different length of time in different plants: thus, while in most species of datura, and in *lychnis dioica*, it loses its power in two days, in the wall-flower it remains efficacious for 14 days; while in the date, cannabis, tea, and camellia, it will keep fresh for a year; indeed, Micheaux mentions that the pollen of the date has been successfully used after 18 years! The quantity of pollen that is produced is much greater than is actually required for the impregnation of the ovules. Thus, in the firs and pines, the quantity is enormous, probably because of the obstacles here presented to fertilization. The *sulphur showers* occurring in some districts are composed of the yellow pollen carried by the winds from pine forests; and the showers of colored rain which are occasionally noticed are due to a similar cause. The number of pollen-grains in certain flowers has been calculated. In a plant of *cereus grandiflorus*, Morren observed that there were 40 flowers, each containing 500 stamens, and that each anther contained 500 pollen-grains; hence the entire number of pollen-grains in each flower was 250,000, and in the

whole plant is 10,000,000. Similarly, in an entire rhododendron plant, the pollen-grains amount to 72,620,000. The quantity required for fertilization is very small—one, two, or at most three grains being sufficient to impregnate one ovule. In most cases, the pollen of a single anther is sufficient for complete impregnation; the additional anthers being, as it were, added for the purpose of insuring the result. During the evolution of the stamens, and the maturation of the pollen, the pistil undergoes certain changes, of which the most important is that the stigma becomes enlarged, lax, and covered with a viscid secretion, which, besides detaining the pollen-grains, causes them to protrude their tubes, as already described; moreover, in some flowers the style, which is sometimes covered with hairs, elongates during the discharge of the pollen, brushes the latter on to the pistil, and thus acts directly in fecundation. One of the central cells of the ovule now becomes much enlarged and developed, so as to form the embryo sac. At the end of this sac, next to the micropyle, several free nucleated cells are formed, to which the name of embryo vesicles, or germinal vesicles, has been given. In this way the ovule is prepared for the action of the pollen, and for the production of the embryo plant. The tubes developed by the pollen-grains, when acted on by the secretion of the stigma, pierce the stigmatic tissue, and carry the fovilla through the canal of the style to the ovule, as shown in fig. 7. In some plants the emission of tubes begins in half a minute after the pollen has been caught by the stigmatic secretion; in other cases it does not begin for 24 hours or more; and it is said that in the larch, the tubes do not emerge for 35 days. The length to which the tubes extend is often very great, but the diameter is extremely small. In *colchicum autumnale*, in which the style is 13 in. long, the length of the tube is 9,000 times the diameter of the grain from which it proceeds. The time taken by the tube to traverse the length of the style varies, but does not always correspond with the latter. In some short-styled plants, the time is very long, while in the long-styled *colchicum autumnale*, the pollen-tube reaches the ovule in about 12 hours. In some coniferous plants a year is required for the process.

We now proceed to consider the embryogeny of (1) gymnospermous and (2) angiospermous phanerogams. In the gymnospermous or naked-seeded flowering-plants, such as the coniferæ and cycadaceæ, impregnation is effected by direct contact between the pollen and the ovule, there being no true ovary bearing a stigma. The process is thus summarized by Balfour: "In gymnospermous plants, there are stamens containing pollen, and ovules supported on cones or altered branches, and in them the pollen enters the large micropyle of the ovule without the intervention of stigma or style. When the pollen reaches the nucleus of the naked ovule, it remains long dormant, and after many weeks and months, sends out a tube which reaches the embryo sac, and impregnates a corpuscle. One of the cells of the corpuscle then takes an active function, and develops the embryo with the suspensor in the midst of endospermal cells."—*Op. cit.*, p. 600. In the angiospermous phanerogams, when the pollen-tube has traversed the tissue of the style, and reached the ovule, it proceeds through the foramen, or micropyle, so as to come in contact with the embryo sac; and consequent on this is the development of the cellular embryo. There is, however, much dispute as to what now occurs. "Schleiden thinks that the end of the pollen-tube introverts the embryo sac, and in some cases perforates it, and that it becomes the first cell in the embryo. Most physiologists, however, agree in thinking that Schleiden was mistaken in regard to the extremity of the pollen-tube, and they believe that the embryo is formed from a distinct cell previously existing in the embryo sac. In some instances, the pollen-tube indents the embryo sac, at other times it perforates it, and comes into actual contact with a cell contained in the sac. In the embryo sac there are produced, before impregnation, certain cells, often three, which are called germinal vesicles, only one of which in general is impregnated by the pollinic fluid, which transudes through the membrane of the pollen-tube and the walls of the embryo sac and vesicles. After impregnation, the vesicle divides by a transverse septum into two parts, the upper portion forming a confervoid partitioned filament or suspensor, and the lower becomes filled with cells, constituting the rudimentary embryo. The suspensor is attached to the part which forms the radicle of the embryo, and at the opposite end, one or two cotyledons are produced, inclosing the fresh bud or plumule. An embryo is usually produced in each ovule (monembryonomy); but when more than one germinal vesicle is impregnated, there is a plurality of embryos (polyembryonomy). When the pollen of one species is applied to the pistil of another species, we occasionally find seeds produced which give rise to individuals intermediate between the two parents: these individuals are called hybrids or mules, and are rarely fertile. A plant has, however, a preference

FIG. 8.

Section of part of the ovule of a species of Speedwell (*Veronica triphyllos*), showing the pollen-tube, *a*, passing through the cellular tissue of the nucleus, and reaching the embryo-sac, which contains the rudimentary embryo, *d*, attached to the sac by its suspensor, *b*, and endospermal cells, *e*, at the lower part of the sac.

for the pollen of its own species, and hence hybrids are rare in nature."—Balfour, *op. cit.*, p. 600. A reference to the preceding figure of a section of part of the ovule of a species of *Speedwell*, will elucidate the above summary: it shows the pollen-tube *a*, just as it reaches the embryo sac which contains the rudimentary embryo, *d*, attached to the sac by its suspensor, *b*, and endospermal cells, *c*, at the lower part of the sac. The suspensor is sometimes of considerable length, and as much as three, or even five times the length of the whole seed. Its attachment to the radicular end of the embryo is shown in fig. 8. In monocotyledons, a single sheathing cotyledon is developed; in dicotyledons, two opposite leaves; and after their formation, the apex produces the terminal bud or plumule. The embryo is thus suspended in an inverted position in the seed.

It is impossible to enter into any general description of the organs or process of reproduction in cryptogamic plants. In this great division of the vegetable kingdom, the organs of reproduction are in general obscure, and consist usually of cellular sacs of two kinds—one being called *antheridia*, containing *phytozoa* or *spermatozoids*, representing the stamens, or the male; and the other being called *pistillidia* or *archegonia*, and representing the pistil, or the female. In the fully developed state of the plant, the antheridia disappear, while the pistillidia are transformed into cellular sacs containing germinating bodies known as spores (q.v.), which are considered as being formed by a process of reproduction, and as being analogous to cellular embryos. These spores are developed in mother-cells, the contents of which often divide into four, such mother-cells being called sporidia. With regard to the antheridia and the pistillidia in the different orders of cryptogamic plants, Dr Balfour observes that in ferns they are supposed to exist in a pro-thallus or cellular expansion produced by the spore when it germinates. A cell of the pistillium (the ovular body) afterward gives rise to the spore-bearing leaves (the fronds). After impregnation, the archegonial cells give rise to a sporingiferous frond. The spores are contained in sporangia, with or without an elastic ring, developed on the back, on the side, or at the base of the leaves. In mosses, these organs are seen at certain stages of the plant's growth, and they are either on the same or on different plants. After impregnation, the archegonial cell gives rise to a stalked theca or sporangium with its spores. In liverworts, they are usually on different parts of the plant, and as frequently in the substance or on the under surface of disk-shaped cellular stalked expansions. Here the impregnated cell gives rise to the fruit or capsules. In lichens, the existence of these organs has not been already established; and the fructification consists of *thecæ* or *asci*, containing 4, 8, 12, or 16 sporidia (or cells containing spores) in their interior. These thecæ are usually united together so as to form a cup-like mass of fructification. When mature, the sporidia or thecæ burst, and discharge the spores. The fungi, antheridia, and pistillidia are obscure, and the organs of reproduction are spores which are either naked or are contained in thecæ. In algæ, antheridia and pistillidia have often been detected; but in some of them, certain cells, in the same or separate filaments, seem to possess the property of producing spores by a process of conjugation or union; and in the lowest forms the cells undergo division into new individuals.

Besides the above-noticed modes of propagation, cryptogamic plants are also propagated by buds or gemmæ, which are either attached to the leaves or fronds, or are contained in peculiar cup-shaped bodies. See Carpenter's *General and Comparative Anatomy*, and Balfour's *Class-book of Botany*, from which we have borrowed freely.

VEGETABLE TISSUE, the term employed in botany to denote the whole substance of which plants consist; regarded according to its structure, rather than to functions or chemical composition. See Cellular Tissue and Vascular Tissue.

VEGETARIANISM, the doctrine that vegetable substances are the solids intended by nature for the sustenance of man, and that it is wrong—against nature and against good morals—for men to make use of an animal diet. There have never been wanting among speculative persons some who maintained that fruits and vegetables are the proper food for men; and illustrious names, such as those of Pythagoras, Plato, Plutarch, in ancient times—of Rousseau, Shelley, Swedenborg, in modern, can be counted among the upholders of this doctrine. A society for promoting the practice of vegetarianism was established at Manchester in 1847; and three years later, a similar society was established in the United States. Besides a short-lived publication called the *Vegetarian Advocate*, the vegetarians in Great Britain have been represented by the *Vegetarian Messenger* (monthly), from 1849 to 1859; for one year by the *Journal of Health;* from 1861 to 1871 by the *Dietetic Reformer and Vegetarian Messenger* (quarterly); and since 1871 by the *Dietetic Reformer* (monthly). The vegetarian creed has attracted very few disciples in England; and by these the advocacy of it has usually been conjoined with that of temperance, peace, homeopathy, and the cold-water cure.

There is, first, a physiological argument used in behalf of vegetarianism. It is said that the formation of the teeth and of the intestines in man proves that man was not intended to be a carnivorous, but a fruit and vegetable eating animal. Then it is maintained that a vegetable diet is the most favorable to man, in all respects, physical, intellectual, and moral; that with it, his life is longer, his enjoyment of life greater, his brain more vigorous, and his power of manual labor not less than with an animal diet; and that,

while the use of animal food begets ferocious dispositions, a carelessness about life, a callousness to the sufferings of men or animals, a vegetable diet "develops the gentler affections, and produces a broad and genial sense of brotherhood." It is affirmed that animal food produces febrile and inflammatory tendencies; that, like alcohol, it is a stimulant (some vegetarians call it a stimulating poison); and that a mixed diet is open to all the objection which lie against moderate drinking. It is also alleged that animal food as exposed for sale is often tainted with some disease or unwholesome condition, and that it thus becomes a frequent cause of disease in men. Moreover, it is submitted that vegetables contain all the principles necessary for the sustenance of man; that, therefore, the use of flesh is unnecessary; and that this being so, it is selfish, cruel, and tyrannical—calculated, too, to increase selfishness, cruelty, and tyranny in men—to cut short the existence of inferior animals.

The opinion of physiologists is not favorable to vegetarianism. The structure of man's organs is held to prove that nature intended him for an omnivorous animal, his stomach and intestines being fitted for deriving nourishment from every kind of food, and he being able, by means of cooking, to modify his food so as to prepare it for mastication and digestion. There is also almost a concurrence of medical experience against vegetarianism, and in favor of the opinion that man, as regards all his powers and faculties, thrives best, and that—if a difference can be made out—he also lives longest upon a mixed diet. It has been found, in making railways, that differences between workmen in respect of bodily strength and energy were chiefly due to a difference of diet; that, for example, a beef-eating Englishman would almost do the work of three vegetable-fed Frenchmen, and that this difference of working-power disappeared when the Frenchmen took to eating beef. Upon the alleged beneficent moral influence of vegetable food, it may be observed that there is no proof whatever of its reality; moreover, that since the majority of mankind live either mostly or entirely upon vegetables, vegetables must bear a large share of the responsibility which may fall upon diet for the evil tendencies of man, and that, in fact, the most cruel and the most debased of human races live entirely upon vegetables. To the charge of cruelty brought against the practice of killing animals for food, it has been answered, that the plan of nature contemplates such cruelty—if cruelty it be—and makes it impossible to avoid it; that the microscope has shown us that even in taking a draught of water we may deprive a multitude of beings of life; and that, on the other hand, the system of rearing cattle for the butcher—since the cattle would otherwise not be reared at all—really adds very largely to the sum of happy animal existence. It is not disputed that there is a liability to disease from the use of unwholesome meat; but, then, vegetables as well as animals are subject to diseases: and the reasoning which would drive us from the use of animal food because it may be diseased, would really cut us off from food altogether.

VE'GLIA, an island of Austria, in the Adriatic sea, belonging to the government of Triest; pop. 19,871. The channel of Morlacca separates it from the main-land and the islands of Cherso and Plannich on the s.w. It is 23 m. long and 12 m. in width. The coast is bold and rocky. The surface is mountainous and well timbered, and the soil in the s. and w. is fertile, producing wine and a variety of fruits. The chief mineral product is marble, and the principal industries are connected with the fisheries. On the s.w. coast is the town of Veglia, with a harbor and fort and a pop. of about 2000.

VEHMGERICHTE. See FEMGERICHTE.

VEHSE, KARL EDUARD, 1802–70; b. Germany; appointed head of archives department at Dresden in 1833. He traveled in the United States in 1839, was expelled from Prussia for his remarks about the royal family in his *Geschichte der deutschen Höfe Seit der Reformation*, 1851–58, and naturalized in Switzerland in 1857. He published *Geschichte Kaiser Otto's des Grossen* in 1828.

VE'II, an ancient city of Etruria in early times the formidable rival of Rome. Its very site is disputed, but is now generally thought to be at *Isola Farnese*, about 12 m. from Rome. The struggle between the two cities is recorded by Roman historians to have commenced as early as the time of Romulus, and to have continued under each of the kings, except the pacific Numa, and always to the advantage of the Romans. The Veientines had their revenge so far under Porsena; but after his time, being convinced by repeated defeats that they were no match for their enemy in the open field, they had recourse to the plan of sheltering themselves behind their walls on the approach of the Roman legions, and of sallying out on predatory expeditions as soon as they had retired. To relieve the republic from this annoyance, the Fabian clan, to the number of 306, with their followers, probably ten times as numerous, undertook to garrison a fortress near Veii, and act as a guard against the marauders. They were, however, enticed into an ambuscade, and cut off to a man at the Cremera. For the next 60 years, hostilities often broke out, followed by ill-observed truces. At last, the Romans determined to rid themselves of their rival by a siege, and persevered with great tenacity, though the city held out for ten years, and repeated attempts were made by the neighboring states to relieve it. It is said to have been taken at last by a mine, which was directed so as to lead into the citadel. The citizens were massacred or sold as slaves, and the land confiscated. The fall of Veii took place 396 B.C. It was debated more than once, especially after the destruction of Rome by the Gauls, whether Rome should

not be abandoned, and Veii made the capital. After its fall, it was gradually deserted; and although, in later times, a colony was planted there by Cæsar, and again by Augustus, it always remained an insignificant place. There are remains of the Etrurian, and also of the Roman city, which have latterly been traced out and described.

VEIL. This familiar article of dress is one of the most ancient in use; its origin is lost in remoteness, but we find an allusion to the wearing of veils by the Chinese in Ovid, and Juvenal speaks of women as being so delicate as to be overheated by a silken veil. Although generally considered portions of female dress, we read in the works of Ambrose (374 A.D.), of "silken garments and veils interwoven with gold, with which the body of the rich man is encompassed." Its use is now so extended that it may be found in every part of the civilized world, but almost exclusively confined to women.

VEINS, in anatomy, if we except the pulmonary, the portal, and the umbilical veins, are the vessels which carry back venous blood from the capillaries, and enlarging as they proceed, finally pour it through the ascending and descending *venæ cavæ* into the right auricle of the heart. See CIRCULATION. Their coats are similar to those of the arteries, but much thinner, and even transparent. They are, however, of considerable strength. The *internal coat* consists of an epithelial layer, supported on several laminæ of longitudinal elastic fibers. The *middle* or *contractile coat* consists of numerous alternating layers of muscular and elastic fibers, the muscular fibers being disposed circularly round the vessel. The muscular fibers are wanting in some parts of the venous system, and specially developed in others (as, for example, the splenic and portal veins, where, perhaps from the physical character of the tissues which they pervade, there may be more than the ordinary resistance to the passage of the blood). In the *venæ cavæ* and pulmonary veins near the heart, striped muscular fibers may be detected, continuous with those in the auricles. The *external* or *areolar fibrous coat* consists of connective or areolar tissue, and of longitudinal elastic fibers; within some of the larger veins, as the inferior *vena cava*, through its whole length, the external iliacs, the azygos, etc., there is also a longitudinal net-work of unstriped muscular fibers. The existence of valves in the veins is mentioned in the article CIRCULATION. These valves are most numerous in the veins of the extremities, especially the lower ones, these vessels having to act against the force of gravity more than most others. They are absent in the *venæ cavæ*, the hepatic, portal, renal, pulmonary, and some other large veins, and in very small veins generally. The veins are nourished by nutrient vessels, or *vasa vasorum*, like the arteries; but except in a few instances (including the inferior *vena cava*), nerves are not distributed to them.

The chief diseases of the venous system have been already sufficiently described in the articles PHLEBITIS, OR INFLAMMATION OF THE VEINS; PHLEBOLITES; PHLEGMASIA ALBA DOLENS, OR MILK-LEG; THROMBOSIS; and VARICOSE VEINS. We shall here merely refer to two conditions of the venous system which must be regarded as the results of natural rather than morbid action: they are *hypertrophy* and *atrophy*. Hypertrophy is a natural and healthy change, which will be readily understood by one or two illustrations. When the uterus enlarges during pregnancy, the quantity of blood in it increases in at least a corresponding ratio, and so also do the venous canals by which it is removed; while shortly after delivery, they return to their natural size; the hypertrophy being accompanied with a proportionate dilatation. This form of hypertrophy, with dilatation, often exerts a compensative action, one vein, or set of veins, taking additional work (and consequently requiring an increase of caliber), to make up for the partial or entire occlusion of another. When, for example, the ascending vena cava is diminished in size, or even entirely and permanently closed, it is well known that the lower portion of the vessel dilates in common with the branches entering into it, and that the superficial abdominal veins or azygos, or both, become enlarged, and thus carry to the heart the blood which ought to have reached the heart by the usual course. If the obstruction is only temporary, the enlarged veins return to their original state, except that additional transverse fibers are found in the middle coat. Atrophy of the veins accompanies the corresponding changes of other tissues, when a part is permanently diseased. Amputation above the knee soon reduces the femoral vein to less than one-third of its previous size. Mr. Callender, in his article on diseases of the veins, in Holmes's *System of Surgery*, states that in the case in which a kidney became transformed into a large cyst, the canal of the renal vein was impervious to a common probe; and this condition is daily seen in the change which occurs in the umbilical vein shortly after birth.

VEINS, in geology, are crevices, more or less vertical, caused by the contraction during drying or metamorphoses, or by the mechanical disturbance of a rock, which have been filled by materials different from the body of the rock. Veins containing substances that have been injected in a state of fusion from heat, have had their origin in some internal force; while those filled with mineral deposits may or may not be connected with upheaval. Granitic and trappean veins differ from dykes chiefly in the greater size of the latter. They produce similar changes in the rocks which they penetrate, indurating clays and sandstones, and converting limestones into marble, or giving them a compact texture like hornstone. Granite veins are generally more sinuous in their course than those of trap. One set of veins often intersects another, having been produced at a later period; and the two sets generally differ in color, grain, and even

mineral composition. Granite generally assumes a fine grain, and is even different in composition in the veins it sends into the adjoining rocks. Mineral veins are filled with different kinds of crystalline minerals. Quartz and calcite are the most common of these substances; but frequently several different minerals occur in the same vein, some of these being metallic ores. Veins of the same age are filled with the same metals, and generally maintain a general parallelism of direction. Thus, the tin and copper veins of Cornwall run nearly e. and w.; while the lead veins run n. and south. Three kinds of veins are distinguished by the miners—rake, pipe, and flat veins. The rake veins are simple crevices, crossing all the rocks of a series, generally highly inclined, and apparently formed from the contraction of the rock. The two originally opposite surfaces may retain their relative positions, only separated by the interposed contents of the veins; or a fault may place the originally contiguous surfaces at different levels; and in such a case, the intervening spaces between the walls of the vein are irregular, sometimes narrowing so that the walls are in contact, and then widening out, and forming large cavities containing ores. The pipe veins are irregular cavities, filled with minerals, and without any apparent connection with faults in the strata. Flat veins have a general direction corresponding with that of the stratification, and are connected sometimes with rake veins, and sometimes with pipe veins. The manner of working the minerals contained in veins is explained in the article MINING (q.v.).

VEIT, PHILIPP, a distinguished German painter, was born at Berlin, Feb. 13, 1793. His mother, a daughter of Moses Mendelssohn, had for her second husband, Friedrich Schlegel, and Veit became devotedly attached to the religious and artistic ideas of his stepfather, whom he followed in his renunciation of Protestanism for Roman Catholicism. After finishing his studies at Dresden, he proceeded to Rome in 1815, and became a very prominent member of that coterie of young German painters who sought to infuse into modern art the purity and earnestness of mediæval times. Of all the associates, Veit ventured furthest into the obscure realms of symbolism and allegory. His first famous work was the "Seven Years of Plenty," executed as a companion-piece to Overbeck's "Seven Years of Dearth," and forming part of a series of frescoes illustrative of the history of Joseph, painted at the Villa Bartholdy in Rome. In richness and freshness of invention, it is reckoned one of the best works of the school to which it belongs. Other pictures of a high order of merit, done during his residence at Rome, are "The Triumph of Religion" (Vatican galley), "Scenes from Dante's *Paradiso*" (Massimi Villa), and an altar-piece, representing "Mary as Queen of Heaven" in the Trinità de' Monti. These procured him so great a reputation that he was called to the directorship of the Städelsche art institute, in Frankfurt-on-the-Main. While holding this position, he produced many grand pictures, of which the most celebrated is the large fresco (at the institute), representing "Christianity bringing the Fine Arts to Germany," held by many to be the finest fresco by any modern artist. Others are, "The Two Maries at the Sepulchre," and "St. George." In 1843 he resigned his post as director, and removed to Sachsenhausen, in Hesse-Cassel. Among his later works are, "The Ascension of the Virgin," "The Good Samaritan," "The Egyptian Darkness," and "Glorification of the Christian Faith in its Alliance with the Reigning House of Prussia," for the king of Prussia. In 1868 he painted several frescoes for the Mayence cathedral. He died, December, 1877.

VE'LA, VINCENZO, b. Switzerland, 1822; in youth a stone-cutter; in 1836 studied drawing and worked in studios at Milan. He afterward spent some time in Rome and Venice and settled in Turin, 1849. He produced a number of statues and bas-reliefs; among which are "Spartacus;" "Harmony in Tears;" "France and Italy;" "Columbus and America;" and "Napoleon in St. Helena;" the last two now in possession of the Metropolitan art museum, New York. He d. in 1891.

VELASQUEZ, DIEGO RODRIGUEZ DE SILVA, one of the most famous of Spanish painters, was b. at Seville, in June, 1599, of a family of Portuguese origin. Very early, the bent of nature became obvious in him; and he was sent to be educated in the studio of Francisco Herrera el Viejo, an artist of considerable force and originality. He afterward became the pupil of Francisco Pacheco, a man accomplished in theory, but who could practically teach him little. The old pedant had, however, an attractive daughter, named Juana, who, doubtless, to the eyes of the young painter, atoned for her parent's deficiences, and who married him at the end of 5 years. His chief education, however, as with all men of real genius, was that which he gave himself; he painted assiduously from the life; the models he selected were, for the most part, of the sordid peasant class, and in this way a certain habit of mind was induced, unfavorable to the attainment of that pure and elevated ideal, some infusion of which is all that is wanted to elevate the noble realistic hardihood of his manner into the very highest region of the art. In 1622, he paid a visit to Madrid, to study the treasures of art there accumulated. During his stay, he painted the portrait of the poet Gongora, and made some influential friends, at whose instance he was, the year after, invited to return by the conde, Duque de Olivarez, the favorite of Philip IV. His portrait of this magnate so delighted the king, that he himself sat to the artist, and the result was a picture of superb merit by the public exhibition of which the artist at once became famous. The office of court-painter was bestowed upon him, and he found himself at once embarked on a full tide of the prosperity which continued through life to flow upon him. Of Philip IV. and his fam-

ily he painted many pictures; and shortly after his appointment, he executed a portrait —unfortunately lost—of Charles I. of England, then (1623) at Madrid on his famous fool's errand. The year 1628 was made memorable to him by the arrival, in Madrid, of the great Rubens, on a diplomatic mission The two artists were worthy to become friends, and speedily became so; but though Rubens, during his stay, was assiduous in the practice of his art, the familiarity of Velasquez with his florid harmonies of color and riot of animal vigor, seems to have exercised no modifying influence on the restrained gravity and severity of his own style, now thoroughly matured.

Velasquez had long desired to visit Italy; and in 1629, permission was granted him to proceed thither. Everywhere he was received with the highest honors; and in Rome, in particular, Pope Urban VIII. assigned him apartments in the Vatican. Here he chiefly employed himself in copying the frescoes of Raphael and Michael Angelo; and it is remakable that, in the one or two original pictures which he at this time produced, no hint of an influence can be traced from his studies of these mighty masters. He was not the less profoundly sensible of their power; though he has left it on express record, that of all the Italians he considered Titian the greatest. Such, however, was his powerful individuality, that his own style once formed, no such external influence was able to affect it appreciably. Having recovered from a severe illness, he proceeded to Naples; and finally, in the spring of 1631, returned to Madrid, where he was cordially welcomed by his royal patron, with whom he now became more and more a favorite. He had a painting-room in the palace assigned him; and the king was wont to come familiarly to watch him at work. It is a noble trait in the man, which deserves to be recorded along with his triumphs as an artist, that when, in 1643, the Duque de Olivarez, to whom he had been indebted while yet obscure, incurred disgrace at the hands of Philip, he braved the royal displeasure, by continuing to show him in everything the respect to which he had been accustomed. In 1648 Velasquez proceeded again to Italy, on a mission from the king to buy pictures and other works of art. He returned to Madrid in 1651; after which time many of his finest works were painted. Such was the favor in which he continued to be held by Philip, that, in 1656, the cross of Santiago was conferred on him, an honor never before awarded except to the highest of the nobility; and shortly after, he was appointed aposentador mayor. This post, the duties of which consisted in attendance on the king in his journeys, and superintendence of everything essential to his convenience, was one of much honor and emolument; but it involved at times great trouble and anxiety; and on the specially important occasion of the conferences held, in 1660, to arrange the marriage between Louis XIV. and the Infanta, these were such as to utterly prostrate the painter. On July 31 of that year, he returned to Madrid, worn down with the overwork to which he had been forced to subject himself, and died in a week after, on Aug. 7. He was buried with much ceremony in the church of San Juan. His wife, who was passionately attached to him, only survived his loss about a fortnight.

Velasquez—with the doubtful exception of Murillo—takes admitted rank as the greatest of Spanish painters. His portraits are, for force, penetration, directness, and severity of truth, of almost unrivaled merit; his historical pictures are also of rare value; his landscape effects are full of air and light; and his treatment of religious subjects only fails in defect of that deeper spirituality, the expression of which has been in its fulness attained by none save a few of the earlier Italians. The works of Velasquez are in this country rare. The few specimens to be found in the national gallery in London inadequately represent his genius, of the power and variety of which a worthy conception is only to be formed at Madrid. See Stirling-Maxwell's and Stowe's works.

VELEZ-MALAGA, a t. in the s. of Spain, in the modern province of Malaga, and 16 m. e. of the city of that name. It stands at the foot of a hill which forms part of the south range of the Sierra Tejada, and rises with its fortress and its spires overlooking the river Valez, at a distance of less than two miles from the shore of the Mediterranean. The climate, said by the Andalusians to be "that of heaven," is delightful; and owing to the abundance of moisture supplied by the hill-streams from the north, and the heat of an almost tropical sun, the vegetation of the vicinity is of the most luxuriant description. The aloe, palm, sugar-cane, prickly pear, orange, vine, olive, indigo, and sweet potato (*Batata de Malaga*), grow here abundantly. There are here the ruins of a Moorish castle, with a small tower. The town was taken from the Moors by Ferdinand the Catholic, after a long siege. Pop. (1887), 23,425.

VELIKI-LOUKI, a t. of Great Russia in the government of Pskov, on the river Lovat, 130 m. n.w. of Smolensk. It is one of the most ancient towns of Russia, having belonged to Novgorod before the annexation of that territory to Moscow. Boots are largely manufactured, and exported to St. Petersburg. Pop. '93, 7478.

VELIKI-USTIUG, or USTIUG-VELIKI, a trading-t. of Great Russia, in the government of Vologda, at the confluence of the Jug and the Suchona, 350 m. s.e. of Archangel. It was founded in the 13th c. by a colony from Novgorod. It exports grain, leather, flax, etc., and imports manufactures and colonial wares. Pop. '93, 8513.

VELINO, CATARACT OF. See TERNI.

VELLE'IA, or VELEIA, a t. of ancient Liguria, situated among the northern slopes of the Apennines, 18 m. s. by e. of Placentia (Piacenza). Little information respecting

it can be gleaned from the Latin writers. The Veleiates are mentioned by Pliny among the Ligurian tribes, and seem to have been subjected to Rome in 158 B.C. The t., however, dates from the time of Tiberius, and appears, according to the traditionary account, to have been overwhelmed by a land-slip of the mountains Moria and Rovinazzo, the earth having been loosened by the percolation through it of the waters from a lake high up in the mountains. A comparison of the soil which covers the city with that of the mountains, confirms this story, though, strange to say, there is not the slightest notice in Roman history of such an event having happened. Velleia remained hid and forgotten till 1747, when a field-laborer turned up a tablet of bronze, on which Trajan's alimentary law for the public maintenance of 279 children was written. This tablet, which measured about 8 ft. 8 in. by 5 ft. 9. in., Paris measurement, and weighed 7,200 ounces, narrowly escaped being melted down for bell-metal; and in 1760 excavations were commenced by the directions of the duke of Parma at the place where the tablet had been found. The result of these investigations, which were continued till 1765, was the discovery of a forum, in which was another bronze tablet of a smaller size than the one previously found, an amphitheater, baths, 12 marble statues, numerous small bronze statues, medals, coins, stamps, inscriptions, and bronze instruments of various kinds. From none of the coins discovered being of later date than the time of Probus, it has been supposed that the catastrophe which overwhelmed the city happened either during or soon after his reign. The museum at Parma contains most of the antiquities which have thus been rescued from the bowels of the earth.

For about a century previous to 1747, it was known to a very few that ancient treasures were concealed at the place where the town was subsequently discovered; and so much wealth in coins and gold statues was discovered by a poor priest belonging to the adjoining village of Macinisso, that his family became ennobled.

A few trifling excavations have been made since 1765, but they have now been discontinued for a number of years.—See *La Rovina di Veleia, misurate e disegnate da Giovanni Antolini,* etc. (Milano, 1819); and *Tavola Legislativa della Gallia Cisalpina ritrovata in Veleia da D. Pietro di Lama* (Parma, 1820).

VELLE'TRI, a city of southern Italy, in the province of Rome, is walled, well built, and situated on a hill, 26 m. s.e. of Rome. The principal buildings are the cathedral, an ancient Gothic structure; and the Ginetti palace, with a marble staircase, esteemed the finest in Italy. The hill of Velletri, which, like the surface of all the county between it and Rome, exhibits evidences of volcanic action, produces good wines. Pop. about 13,000.

VELLORE, a t. and fort of British India, presidency of Madras, in the district of Arcot, 80 m. w. of Madras, on the right bank of the Palar. The fort is extensive, is surrounded by a ditch cut in solid rock, and contains barracks, hospitals, etc. The t. is large, clean, and airy, and has an extensive and well-supplied bazaar. The t. contains a most remarkable and splendid pagoda, dedicated to Krishna, whose adventures with the *gopis,* or milkmaids, are represented in a series of elaborate sculptures. Although the heat of Vellore is great, it is considered one of the healthiest stations in the Carnatic. Vellore was the residence of Tippo Sahib's family from 1799 to 1806, when they were removed on account of a sepoy mutiny, which resulted in a terrible massacre of Europeans. Pop., with cantonments, 1891, 44,925.

VELLO'ZIA, a genus of plants of the natural order *hæmodoraceæ,* natives of Brazil, southern Guiana, and the Mascarene islands. They are sometimes called *tree lilies.* They are perennials, with trunks closely covered by the withered remains of leaves, branching by forks, and bearing tufts of long, narrow, aloe-like leaves at the extremities of the branches. Some of them are from 2 to 10 ft. high, and the trunk is sometimes as thick as a man's body. The structure of the trunk is very remarkable. It has a slender sub-cylindrical central column, of the ordinary monocotyledonous structure, outside of which are arranged great quantities of slender fibrous roots, which cohere firmly by their own cellular surface and form a spurious kind of wood. In some of the southern districts of Brazil, vellozias are found covering large tracts. The flowers of the larger species are about 6 in. long, either pure white, or of a beautiful purple color, much resembling the white lily of our gardens.

VELLUM. See PARCHMENT.

VELOCI'PEDE, a vehicle, consisting of two wheels placed one before the other, and connected by a frame-work, affording a seat for the rider, by whom the vehicle is propelled by means of pedals working a crank attached to the forward wheel. The first known velocipede was invented in 1817 by M. Drais of France, propelled by striking the ground with the feet. In the more modern vehicle the equilibrium is maintained by the momentum in a certain plane, and by the motion of the rider's body and limbs. About 1867, greatly improved forms of the velocipede were introduced, and the exercise became very popular. Among the feats performed were the riding of 100 m. in 7 hours and 43 minutes by David Stanton, and of 132 m. in 12 hours and 15 minutes by J. T. Johnson. Within a few years the velocipede in its old form has given way to the bicycle and tricycle. See BICYCLE: TRICYCLE.

VELOCITY (Lat. *velox,* swift) is the common term employed to denote speed, or *rate of motion.* It is obviously greater the greater the space passed over in a given time.

But, for its accurate measurement, we must distinguish between uniform and varying velocity.

Nothing is easier than the measurement of uniform velocity. It is measured by *the space passed over in a unit of time.* Thus, we speak of velocities of 10 ft. per second, 20 m. per hour, etc. But, for scientific purposes, it is best to keep, as far as possible, to definite units of time and space; and those most generally convenient are the *second* and the *foot.* The latter is defined, from the imperial yard, by act of parliament: the former is usually chosen as the interval between the beats of a good mean-time clock. Unfortunately, its duration is not invariable; but, as ages must elapse before any sensible alteration takes place in its length, it may be used without inconvenience. If, then, v be the velocity of a point moving uniformly, we mean that v feet are passed over in each second, so that, if s represent the space passed over in t seconds, we have $s = vt$, a formula which contains the whole properties of uniform motion. It gives $v = \frac{s}{t}$; that is, to find the velocity of a moving point (when uniform), divide the space (in feet) described in *any* period of time by the number of seconds in the period. This will give the same result whether we take a million seconds or the millionth part of a second, as the period in question. This at once shows us how to proceed in measuring a variable velocity, such as that of a stone let fall, in which case the velocity constantly increases, or of a stone thrown upward, in which case the velocity constantly diminishes.

That a moving body has at every instant, however irregular its motion may be, a definite velocity, is obvious, and is in fact matter of every-day remark. Thus when traveling in a railway train we say, shortly after starting. "We are now going at the rate of a mile an hour;" not thereby meaning that it will take us an hour to complete the mile, but that *if we were to go on for an hour with the velocity we now have we should run a mile.* Again we may say: "Now we are going at 30 m. an hour;" not thereby meaning that we have so much as 30 m. to travel, or that our journey is to last more than perhaps a few minutes, but that *an hour at the present rate would take us* 30 *miles.* In common language, then, our question is how to measure our present rate.

If we could at any instant so adjust the steam-power to the resistance of the air and the friction of the rails as to keep the rate unaltered, we should have uniform velocity, measurable with ease, as above shown. But as we cannot generally do this (though Attwood's machine enables us to do it in the case of a falling body), we are driven to some other expedient. Now it is obvious that the smaller the interval we take the less will our velocity have changed during its lapse, i.e., the more nearly will it have become uniform and measurable by the simple formula given above. That is for a variable velocity we have $v = \frac{t}{s}$ as an approximation, which is more and more nearly true as t, and therefore s, is smaller. In the language of the differential calculus—whose fundamental notions as laid down by its great inventor were in fact derived from this very question, the velocity being simply the *fluxion* (q.v.) of the space described—we have $v = \frac{ds}{dt}$. Practically, by means of the electric chronoscope, we can now measure (very exactly) extremely small intervals of time, such, for instance, as the interval between the fall of the dog-head and the exit of the bullet from a rifle-barrel; so that a variable velocity now presents no formidable difficulty, as we can study and measure it *while it is almost absolutely uniform.*

We define *average* velocity as the space described in any time divided by the number of seconds employed. This may not, except at one or more instants during the motion, represent the actual velocity; but it is a velocity with which, if uniform, the same space would have been described in the same time. We shall presently have an opportunity of usefully applying this definition to one interesting case of varying velocity.

The *resolution* and *composition* of simultaneous velocities follow, almost intuitively, from the most elementary geometrical notions. When a man is walking n.e. at a uniform rate, it is obvious to common sense that he is progressing northward and also eastward. What is his northward, and what is his eastward velocity. The answer is very simple. Suppose that in one second he walks from A to B, then AB represents his whole velocity. But draw AN northward and AE eastward; also draw BC parallel to AN. Then AC is the space by which B is eastward of A, BC the space by which it is northward. Hence AC represents the eastward and CB the northward velocity (each being the space in its respective direction described in one second), and these are called *components* of the velocity AB. AB again is said to be *resolved* into AC and CB.

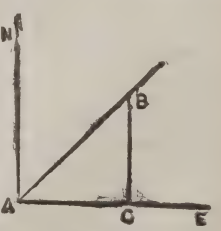

FIG. 1.

The general proposition is this, that a velocity represented by one side of a triangle may be resolved into two, represented in magnitude and direction by the other sides of the triangle. One or both of these may be again resolved by a similar process; and we find, as the most general propositions on the subject, that velocities represented by all the sides of a polygon (whether in one plane or not)

but one, taken in the same order round, are jointly equivalent to a velocity represented by that one side, taken in the *opposite* order, also that a point which has simultaneously velocities represented by the successive sides of any polygon, taken all in the same order round, *is at rest*. The second law of motion (see MOTION, LAWS OF) enables us to interpret this geometrical theorem into the physical truths known as the triangle and polygon of forces in statics.

Rate of change of velocity is called *acceleration*. It is measured in the same way as velocity itself. Thus if the change take place in the direction of motion it affects merely the amount, not the direction of the velocity; and an acceleration α adds (or subtracts, if it be negative) α feet per second from the velocity affected. Thus it is found that gravity produces an acceleration of about 32.2 on all falling bodies; so that if a stone be let fall, its velocity after t seconds is $32.2t$. If it be *thrown* down with a velocity v, its velocity in t seconds is $v + 32.2t$. If thrown upward with the same velocity, in t seconds its velocity becomes $v - 32.2t$, so that it will stop and begin to descend after $\frac{v}{32.2}$ seconds have elapsed.

The space passed over by the stone in t seconds is easily calculated by the help of the *average* velocity. For since in any of the above cases the velocity increases (or diminishes) *uniformly*, its average value during any interval is the average of its values at the beginning and end of the interval. Hence for the stone simply let fall:

Initial velocity $= 0$,

Velocity after t seconds $= 32.2t$,

Average velocity during the first t seconds $= 16.1t$. Hence, space described in t seconds

$= t \times$ average velocity $= 16.1t^2$.

So that the spaces described are as the *squares* of the times.

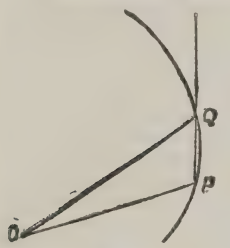

FIG. 2.

But if the acceleration be not in the direction of motion, the direction and magnitude of the velocity will generally change. To exhibit this geometrically, sir W. Rowan Hamilton (q.v.) invented the following beautiful construction of what he called the hodograph of the motion. Let O be any fixed point, and from it draw lines OP, OQ, etc., representing at every instant in direction and magnitude the velocity of the moving point. The extremities of such lines will form a curve, such as PQ in the figure. If OP and OQ be any two of these, the *change* of velocity is represented (as above) by the third side, PQ, of the triangle. As Q is taken nearer and nearer to P, PQ becomes more and more nearly the tangent to the hodograph, so that the tangent at P has the *direction* of the acceleration, and the rate at which P moves round the hodograph is the *magnitude* of the acceleration.

If we consider any uniform motion, we see that the hodograph is a circle (its radius being the magnitude of the velocity), and from this it is easy to see that *in uniform motion the acceleration is always perpendicular to the direction of motion*. If we consider uniform motion, with velocity V, in a circle of radius R, the hodograph at once shows that the acceleration is $\frac{V^2}{R}$, and is directed toward the center of the circle.

Translated into physics, acceleration (multiplied by the mass of the moving body) is the measure of the force which acts on the body. So the above simple example shows that, to keep a mass moving uniformly in a circle, it must be drawn toward the center by a force proportional directly to the square of the velocity, and inversely to the radius. This is the physical explanation of the so-called centrifugal force (see CENTRAL FORCES).

VELOCITY, INITIAL, in gunnery, is the speed with which the ball leaves the muzzle of the gun. This was formerly calculated from the momentum as shown by the ballistic pendulum (q.v.). A great improvement of the last ten years is the electro-ballistic pendulum, the invention of a Maj. Navez of the Belgian service, which actually measures the interval of time during which the shot traverses a short space of ground. The apparatus consists of a steel pendulum falling at the side of a graduated sector of a circle. Behind the segment is a piece of iron capable of being magnetized by a galvanic battery adjoining. The wires for completing the circuit between the battery and the magnet are so arranged that they are in connection with two targets of paper or other thin material in the line of the projectile's fire. So long as the circuit is complete, and before the experiment, the magnet holds the pendulum at its highest point. When the shot pierces the first target, the circuit is broken, the iron demagnetized, and the pendulum released; these effects being absolutely simultaneous. With equal simultaneity, the piercing the second target re-establishes the circuit, magnetizes the iron, and arrests the pendulum in its descent. The distance between the targets is known, and the accumulating resistance of the atmosphere within that time; the sector being finely graduated, the distance traversed by the pendulum shows exactly the fraction of a second occupied, and from these data the initial velocity is a matter of simple computation. Of an ordinary smooth-bore cannon the initial velocity is about 1600 ft. per second.

VELOCITY, Virtual. See Work.

VELPEAU, Alfred Armand Louis Marie, 1795–1867; b. France; studied medicine, and settled in Paris in 1821. In 1830 he was appointed surgeon to the Pitié hospital; in 1835 professor of clinical medicine at the academy of medicine, and in 1842 was called to the same position at the institute. Among his works are: *Traité de l'Anatomie Chirurgicale* (1825); and *Nouveaux Eléménts de Médicine Opératoire* (1832).

VEL'VET, a fabric in which, besides the ordinary warp and weft, which are usually arranged as in twill-weaving, there is also a supplementary weft, consisting of short pieces of silk, cotton, or woolen thread doubled under the regular weft, and brought to the surface in loops which are so close together as to conceal the regular web. The loops are afterward cut evenly, and the ends thus made constitute a covering resembling a very short fur. In silk velvets, the warp and pile threads are both of organzine silk, which is the strongest used in weaving.

VELVETEEN. A cotton fabric whose pile is so cut that it resembles velvet, though less beautiful in texture and less retentive of color. When it has a twilled back, it is often called Genoa. It is of English origin. It was introduced into France in 1740, but was not produced there to good advantage until 1768. Large quantities are now manufactured at Lyons, France, and at Crefeld, Prussia.

VENANGO, a co. in n.w. Pennsylvania, drained by the Alleghany and French rivers; 655 sq.m.; pop. '90, 46,640, chiefly of American birth, with colored. Co. seat, Franklin.

VENDACE, *Coregonus Willughbii* or *marœnula:* see Coregonus, a fish of the family *salmonidæ,* found in the rivers and lakes of Sweden, in the castle loch at Lochmaben in Scotland, and in some of the English lakes. It is popularly said to have been introduced at Lochmaben by queen Mary; but the statement rests on no authority, and is highly improbable, as the fish could not be easily transported, except by the roe, living only for a very short time after being taken out of the water. Like most of its congeners, it is highly esteemed for the table. Its food consists chiefly of *entomostraca,* and it is never taken by angling. Sweep-nets are used for its capture. It generally swims in considerable shoals, often with a remarkable separation of the sexes. It attains a length of 6 or 7 in., is deeper in proportion than many of the salmonidæ, and of a compressed form. The outline rises quickly from the snout to the dorsal fin, and the body tapers rather suddenly at the tail. The under-jaw projects a little. The scales are of moderate size, and do not come off very readily. The tail is broadly forked. The back is brown, the sides tinged with yellow, the cheeks partly white, and there is a curious red, heart-shaped mark between the eyes.

VENDEE, La, a maritime department in the west of France, bounded on the w. by the bay of Biscay, on the n. by the department of Loire-Inférieure, and on the s. by that of Charente-Inférieure. Area, 2,588 sq.m.; pop. '96, 441,735. The department, which owes its name to a small affluent of the Charente, is traversed from e. to w. by a range of hills, called in the e. the Plateau de Gatin, and in the w. the Collines Nantaises; and is watered in the n. by the affluents of the Loire, and in the s. by the Lay and the affluents of the Charente. The territory of La Vendée is divided into three parts, the names of which indicate the character of their configuration. In the w. is the *Marais,* occupied by salt marshes and lakes; in the n. is the *Bocage,* covered with plantations; in the s. and middle is the *Plaine,* an open and fertile tract. The coast-line, 93 m. in length, presents few deep indentations, the chief being the bay of Aiguillon, which affords secure anchorage for vessels. The climate is warm, humid, and unhealthy in the *Marais,* cold and humid in the *Bocage,* and warm, dry, and healthy in the *Plaine.* Cereals, potatoes, flax, hemp, honey, hops, fruit, and vegetables are largely cultivated, and much wine is produced. Among the mineral treasures iron ore and coal are very abundant. There are three arrondissements — La Roche-sur-Yon, Fontenay-le-Comte, and Sables-d'Olonne. The capital is La Roche-sur-Yon. For the *wars of La Vendée* (by which name the armed opposition to the religious and political changes in France is denoted, and which burst out into a species of partisan warfare in 1793, 1794, 1795, 1799, and 1815), see Cathelineau, Larochejacquelein, Hoche, Chouans, etc.

VENDÉMIAIRE (i.e., the "wine-month"), embraced, in the calendar of the first French republic, the period from Sept. 23, to Oct. 21. Particularly memorable in the history of the revolution is the 13th Vendémiaire of the year IV. (Oct. 5, 1795), when the Paris "sections" worked upon by royalist reactionaries in all sorts of ways, rose against the national convention, but were decisively beaten by a military force under the command of Barras, or rather of his lieut., Napoleon Bonaparte, then a young officer only beginning to be known. The victory of the convention saved the republic—for a time.

VENDET'TA, (vengeance), the term used to denote the practice, as it prevails in Corsica, of individuals taking private vengeance upon those who have shed the blood of their relations. In Corsica, when a murder has been committed, the murderer is pursued not only by the officers of justice whose duty it is to punish offenses against society, but also by the relatives of the slain, upon whom the received views of social duty impose the obligation of personally revenging his death. In such a case, the relatives

of the murdered man take up their arms, and hasten to pursue, and if they can find him, to slay the murderer. If he succeed in eluding their pursuit, the murder may be revenged upon his relatives; and as the vengeance may be taken whenever an opportunity occurs, the relatives of a murderer whose crime is unavenged have to live in a state of incessant precaution. When they go to the fields they take their arms with them, and set a watch; at home they have their doors well fastened, and their windows barricaded; and since the avenger is never far distant, they live, in fact, in a state of siege. Instances are on record of persons who were, as the phrase is, "suffering the vendetta," having lived shut up in their houses for 10 or 15 years, and being, after all, shot on the first occasion on which they ventured out of doors. Formerly, when blood had been shed, there was a custom of proclaiming the war of revenge, and announcing to what degree of relationship it should extend; but this custom is gone out of use. Frequently, in the practice of this system of vengeance, each of two sets of relatives has a murder to revenge upon the other; the vendetta, that is, crosses. This is called the *vendetta transversale*. The duty of taking vengeance lies primarily and especially upon the next of kin. Not to take revenge is deemed in the highest degree dishonorable; and any delay in doing so on the part of the next of kin is made matter of reproach by his relatives. When the Genoese were masters of the island, their laws declared the *rimbicco*—the uttering of such reproaches—punishable, as an incitement to murder. But there is seldom occasion for the rimbicco, for the Corsican is brought up to regard the vendetta as the most sacred duty of man. The women instigate the men to revenge by singing songs of vengeance over the body of the slain, and displaying his blood-stained garments. Often a mother affixes to her son's dress a bloody shred from the dead man's shirt, that he may have a constant reminder of the duty of taking vengeance. Although the vendetta usually has its origin in bloodshed, smaller injuries may give rise to it, and even purely casual occurrences. Mediators, termed *parolanti*, often interpose to make up a quarrel. When they succeed, an oath of reconcilement is taken, and this oath is regarded as specially binding. It is infamous to break it; nevertheless, it is broken now and then. Brigandage prevails to a great extent in Corsica, and the origin of the career of a brigand, in almost every instance, can be traced to the vendetta. A man commits a murder out of vengeance; he flees to the hills; it never is safe for him to resume his former life again, and so he turns robber for a living. Besides the vendetta, properly so called, hereditary family feuds are very common in Corsica; and sometimes there are hereditary feuds between whole villages. The great families of the island hand down feuds from generation to generation, in which not only themselves and all their relatives, but all their servants and dependents are involved—the kind of feud which was common in the Italian towns of the middle ages, and which is illustrated in the play of *Romeo and Juliet*.

The origin of the vendetta has often been referred to the lawlessness which prevailed in many parts of Corsica during the period of the Genoese domination, and to the venality which vitiated the Genoese administration of justice. And, no doubt, the insecurity and the mal-administration of justice which existed in Corsica for ages, helped to consolidate this barbarous custom; which, thus consolidated, has been perpetuated by the isolated position of the country, and the absence of civilizing influences. But the explanation of its origin must be sought in more general causes, for it is not exclusively a Corsican custom. On the contrary, it may be safely affirmed that a system of private vengeance, almost precisely similar, has existed among every people during certain stages of its progress—never entirely passing away until government became strong enough to insure redress of injuries, and to restrain the passions of individuals.

In the case of rude tribes, in the savage or semi-savage state, there is on record such a multitude of instances of the existence of the blood-feud, that its universality among men in that state cannot be doubted. Its incidents are usually the same which sir G. Grey found subsisting among the aborigines of Australia, and of which, in his *Journals of Travel in the North-west of Australia*, he has given a vivid description. The Australian tribe usually includes several stocks or bodies of men, between whom blood-relationship is acknowledged; and every member of a stock is bound to assist in taking vengeance for a personal injury done to any of his kinsmen. On the other hand, though a hunt is always made for the actual wrong-doer, the injury may be satisfactorily avenged upon any member of his stock. As in the Australian and similar tribes, there is no relationship acknowledged between members of the same family unless they are also members of the same stock (see article TRIBE), the blood-feud occasionally arrays father against son, and brother against brother. It often leads to the break-up of a tribe.

Of the prevalence of the blood-feud among tribes which have advanced to what is called the patriarchal state also, there is very ample evidence. Among such tribes, the cohesion of the family is very powerful; everything relating to the family is quasi-sacred; and the duty of taking vengeance for kindred blood is not merely a matter of honor, but of religion. Volney's description of the blood-feud, as practiced among the Bedouins, will do for all the tribes of this class; and it might almost stand for a description of the vendetta. "The interest of the common safety," he says, "has for ages established a law among them (the Bedouins) which decrees that the blood of every man who is slain must be avenged by that of his murderer. This vengeance is called *tar*, or

retaliation; and the right of exacting it devolves upon the nearest of kin to the deceased. So nice are the Arabs upon this point of honor, that if any one neglects to seek his retaliation, he is disgraced forever. He therefore watches every opportunity of revenge; if his enemy perishes from any other cause, still he is not satisfied. His vengeance is directed against the nearest relation. These animosities are transmitted as an inheritance from father to children, and never cease but by the extinction of one of the families, unless they agree to sacrifice the criminal, or purchase the blood for a stated price in money or in flocks. Without this satisfaction, there is neither peace, nor truce, nor alliance between them, nor sometimes even between whole tribes." The blood-feud is observed almost precisely as described above, among the Circassians, the Druses, and the numerous hordes of central Asia; it seems to have had the same incidents, too, among similar tribes in ancient times—e.g., among the Greeks of the Homeric period, among the Germans in the time of Tacitus, among the northern nations who overran Europe after the fall of the Roman empire. The Corsican vendetta seems to be the same thing as the Bedouin tar, surviving, with slight modifications, in a secluded island, where the law has never made itself supreme, long ages after the progress of society and the consolidation of government have effaced every trace of it, except at a few isolated points on the neighboring continent of Europe. The vendetta exists in Sicily and in Sardinia, as well as in Corsica; in Calabria also; and it (or we should rather say, the blood-feud) flourishes vigorously among the Montenegrins and the Albanians.

The right of private war which subsisted in Europe in the Middle Ages—introduced by the northern nations who shared the spoils of the Roman empire—was just a modification of the blood-feud. This right belonged only to the nobility, and could be exercised only against men of equal rank. It was usually resorted to on account of insults publicly done, of atrocious acts of violence or bloodshed, and similar injuries. The right of vengeance devolved first upon the next of kin; but all the kindred within the degrees of relationship to which the ecclesiastical prohibitions of marriage extended, were bound to take up the quarrel; and this obligation was so far sanctioned by law, that if any one failed to fulfill it, he was deemed to have renounced his kindredship, and to have lost his rights of succession. Vassals, equally with kinsmen, became implicated in the vengeance of their lords; and every person present when the cause of quarrel arose was required to take side with one or other of the parties. For several centuries, private wars were constantly being waged within the kingdoms of the continent, and the efforts of kings and ecclesiastics to restrain them produced little effect until governments became strong enough to prohibit them, and to enforce the prohibition.

It is now apparent that the vendetta represents a system which prevailed everywhere before the consolidation of society into the state, and the establishment of a police capable of protecting life and property. This system was a rude substitute for government and the administration of justice. The family, or the body of kindred, formed, in fact, a commonwealth of itself; its members held firmly together; and when one was injured, all the little state was injured. The Nagas have no government, and among them the blood-feud is the only check—it is not altogether inefficient—upon the selfishness and the passions of individuals. As society became consolidated, the exercise of this right of vengeance was curtailed—remaining longest with the nobility, who counted it as one of their most valuable privileges, and maintained it as long as possible. They had to surrender it at last, because the state grew strong enough to supersede the action of individuals in redressing injuries, and was able to do this with greater fairness, and without the same admixture of calamitous results. See Maffia and Mala Vita.

VENDÔME, a t. of France in the dep. of Loir-et-Cher, seated on vine-clad hills, on the Loir, which here divides itself into many canals, 20 m. n.w. of Blois. It contains cavalry barracks, a lyceum, a library, a theater; the church of the Trinity, a remarkable edifice; a college; and the ruins of a lofty castle. Manufactures of leather, cotton goods, gloves, and paper are actively carried on. Pop. '91, 9538.

VENDÔME, a very ancient town, and said to have been of importance under the Merovingians, was the capital of the ancient county of Vendomois, which was erected into a duchy-peerage by Francis I., in favor of Charles de Bourbon. Henry IV. conferred it on one of his natural sons, who thus became the founder of the house of Vendôme. In 1870, it was the scene of several conflicts between the French and Germans.

VENDÔME, House of. Vendôme was an old county of France, erected into a duchy by Francis I., for behoof of Charles of Bourbon, the grandfather of Henry IV. On the accession of the Bourbons to the throne, it was reunited to the crown, but again separated from it by Henry IV., who conferred it upon Cesar, the eldest of his sons by Gabrielle d'Estrées. Cesar's eldest son, Louis, duke of Vendôme, married Laura Mancini,* one of Mazarin's nieces, and had by her three sons, the eldest of whom was Louis-Joseph, Duke of Vendôme, the celebrated French general who so distinguished himself

* It is curious to remark the relationship between the opposing leaders in the great war of 1700–13. Vendôme (French) and prince Eugene (allied) were cousins; Vendôme was second cousin to the duke of Burgundy; Eugene was similarly related to the duke of Savoy; and Marlborough (allied) and Berwick (French) were uncle and nephew.

during the war of the Spanish succession. He was born at Paris, July 1, 1654, and made his first appearance on the field of battle as a lifeguardsman during the Dutch campaign of 1672, afterward serving with distinction under Turenne in Germany and Alsace, and under Crequi in Flanders. Released by the peace of Nimeguen (1678), he retired to his château of Anet, near Dreux, where he resigned himself to the most liberal indulgence in all kinds of pleasure. At this time he became compromised in the affair of Lavoisin (see Poisoning); but it turned out that his intercourse with the pretended seer was prompted merely by curiosity. On the outbreak of war in 1688, he was ordered to the low countries, where, under Luxembourg (q.v.), he earned deserved renown at the sieges of Mons and Namur, and the battles of Leuse and Steenkerk; and his high reputation was not diminished by his subsequent conduct in Italy, where he commanded the left wing of Catinat's army at the battle of Marsaglia (Oct. 4, 1693). But Vendôme's brilliant gallantry and military talents had not hitherto succeeded in obtaining for him the honor of an independent command, for it was only too evident that with these valuable qualities were combined inveterate indolence, and careless and disorderly habits, which might, as effectually as the most utter incapacity, ruin the chances of any enterprise under his management. However, the necessities of the case induced Louis ultimately to give him (1695) the command of the army in Catalonia; and he was agreeably surprised at the alertness of Vendôme, who closed a series of brilliant successes by the capture of Barcelona, an exploit which did much to bring about the peace of Ryswick (1697). After five years of inaction, spent in sloth and sensuality, he was dispatched by his sovereign to supersede Villeroy in Italy. His arrival was hailed enthusiastically by the soldiery, who relied implicitly upon his brilliant genius and happy audacity to extricate them from all difficulties, and with whom his excessive laxity in the matter of discipline rendered him a great favorite. The restored confidence of the troops was proved by the victories of Ustiano and San-Vittoria; while the enforced retirement of prince Eugene beyond the Mincio equally showed the superior strategic abilities of their general; and it required the utmost exercise of both to prevent the surprise at Luzzara (Aug. 15, 1702), brought about through Vendôme's usual carelessness, from becoming a total rout. From this time, a slight though temporary improvement in Vendôme's habits is visible; in 1703, he drove the Austrians before him into the Tyrol, repeatedly defeating Starhemberg; when the defection of the duke of Savoy forced him to retreat. The duke, though joined by Starhemberg, was beaten again and again, and at last cooped up in Turin, whither Eugene was advancing to his relief, when the defeat of his advanced guard by Vendôme compelled a halt. The imprudent Frenchman, however, intrusted the difficult duty of holding Eugene in check to his younger brother, the grand-prior, who, though a gallant soldier, was no match for his opponent in generalship; and had not Vendôme returned to Cassano just in time to divide the honors of the battlefield with his opponent, the army of observation would have been scattered to the four winds of heaven. Again, partially stimulated by this narrow escape, Vendôme displayed unwonted vigor, and drove the Austrians into the Trentin; but in the summer of 1706, he was recalled to supersede Villeroy, who had blundered in the low countries, as he had formerly done in Italy. Unfortunately, Vendôme's besetting faults were attempted to be remedied by uniting the duke of Burgundy with him in command; and the want of a thorough understanding between the conjoint chiefs led to the defeat of the French at Oudenarde (q.v.), and to the failure of the attempt to relieve Lille. The cause of these reverses formed the subject of vehement discussions in France, and though undoubtedly Vendôme was mostly to blame, his great reputation gained him the public support; yet Louis XIV. held him in a sort of disgrace for a time. In 1710, a cry of distress arose from Spain, where the British and Austrians were carrying all before them; and in compliance with the urgent request of Philip V. (who had served under Vendôme in Italy) to his grandfather to send him—not a re-enforcement, but only Vendôme, the heroic old debauchee was once more roused up from his lair, and dispatched to Spain. His appearance, like that of Du Guesclin more than three centuries before, brought together as if by magic a numerous army of volunteers; towns, villages, and even religious establishments united in a most enthusiastic manner to contribute the necessary funds, and Philip was settled in his capital before the close of the year. A week after, Stanhope and the British troops were defeated and captured at Brihuega; and on the following day, Starhemberg and the Austrians were completely routed at Villa Viciosa. The grateful monarch raised his deliverer to the rank of a prince of the blood-royal, and presented him with 500,000 livres (£20,000), a gift which Vendôme accepted only to distribute it among his soldiers. Vendôme for the last time relapsed into his usual habits, and after "a month of extraordinary gluttony," died of indigestion at Vinaroz in Valencia, June 15, 1712. Vendôme, of all the descendants of Henry IV. both then and since, bears the strongest resemblance to his great-grandfather; but of the resolute persistency and self-denial of the first and greatest of the Bourbon monarchs, we cannot discern in him the slightest trace.—Saint-Simon's biography of Vendôme, and Voltaire's *Siècle de Louis XIV.*, are the principal authorities for the life of this extraordinary man.

Vendôme's disinterestedness, like his other good qualities, and they were not a few, became a vice from its very extravagance. It is related that one of his domestics demanded permission to leave his service on the ground that he could not stand by to

see a master robbed by his servants in such a barefaced way. "Is that the reason?" said Vendôme; "very well, then, rob like the others."

VENDOR'S LIEN, the equitable lien which the vendor of land has for the balance of the purchase money still unpaid. It is enforced, like a mortgage, which it resembles, by foreclosure and sale. It can be enforced against the vendee, and all persons holding under him, except purchasers for value without notice. The vendor loses this lien if he accept a higher security, a mortgage, for instance, or if he take collateral security from a third person; but he does not waive his lien by accepting the personal security of the vendee.

VENEER (Fr. *fournir*, to furnish), a layer of wood, cut very thin, for the purpose of being glued on to the surface of a commoner kind. Only choice kinds of hard woods are sawn into veneers, and they are usually attached to deal or pine, so as to give all the appearance of being made solid. In this way the more costly kinds of furniture-woods are economically used by the cabinetmaker, for with the improvements which have been effected in the process of sawing, veneers as thin as paper have been produced.

VENEREAL DISEASE. See Syphilis.

VENERIDÆ, a family of lamellibranchiate mollusks, having a regular, closed, bivalve shell; the teeth and laminæ of the hinge near together in a single group under the beak (*umbo*); generally three diverging teeth in each valve; a marked oval impression in front of the beak; the general form similar to that of the cockles (*cardiaceæ*), but usually more flattened. The mantle has a large opening in front; the siphons are unequal, more or less united; the foot is tongue-shaped, compressed, sometimes grooved, and producing a byssus (q.v.). The species, all of which belong to the Linnæan genus *Venus*, are very numerous. They are very widely distributed, but abound chiefly in tropical seas. About forty are found on the British coasts, some of them very common. The veneridæ are generally elegant in form, and often finely colored. Some of them have the shell furnished with long spines, but chevron-shaped lines are their common ornament. The veneridæ first appear in the oolitic rocks, and are more abundant in the present than in any former geological epoch.

VENESECTION (occasionally termed Phlebotomy, and popularly known as Bloodletting or Bleeding) is an incision into a vein, for the abstraction of blood. Although the operation may be performed on many of the superficial veins, it is restricted in this country to the veins at the bend of the elbow. Of these veins, the most prominent are the median-cephalic and the median-basilic; the former being situated on the outer side of the tendon of the biceps muscle, while the latter lies on the inner side, and only separated from the brachial artery by a thin layer of fascia. Hence, from fear of wounding the artery, the median-cephalic should be preferred; but in reality the median-basilic is usually selected, in consequence of its being the more prominent and larger vein of the two. The appliances required are a lancet, a bleeding-tape or narrow bandage; lint, a bowl to receive the blood, a basin of water, and a sponge. The patient being placed in a sitting position, the tape or bandage must be tied sufficiently tight around the middle of the upper arm, or rather lower, to arrest the venous circulation without materially affecting the pulse at the wrist. The forearm having been allowed to hang down till the veins are tense, the operator must make his selection, and taking the blade of the lancet between the forefinger and thumb of the right hand, should fix the vein by pressing his left thumb upon it just below the part he is about to open. Steadying his hand by resting the ends of the three outer fingers on the forearm, he should steadily (and without a jerk or plunge) introduce the point of the lancet obliquely until the interior of the vessel is reached, and the blood is seen rising up. Without penetrating deeper, he should thrust the instrument forward, so as to open the vein longitudinally to a sufficient extent. On now removing the thumb, the blood should emerge in a full jet; and if the stream be scanty, the patient may have a hard body—as a piece of stick or a pocket-knife—placed in his hand, with directions to grasp it firmly, or the surgeon may increase the flow by chafing the palmar surface of the forearm, rubbing from below upward. When a sufficient quantity of blood has been abstracted, the thumb of the left hand should be placed on the wound, and the ligament loosened; a small pad of lint should then be placed over the orifice, the surrounding parts should be cleaned of blood by a sponge, and the pad of lint compressed against the arm by the tape or narrow bandage, applied in the figure-of-eight form, with the crossing of the tape lying on the pad. After the operation the arm should be carried in a sling for a day or two. We have, contrary to our ordinary custom, given the details of the operation, because it is one which, if performed at the proper moment, may be the means of preserving life, and which any person of ordinary intelligence could probably perform more safely, after reading these directions, than the farriers, barbers, etc., who are frequently called upon to perform it in remote country districts and in the backwoods of our colonies. Among the occasional ill consequences of venesection may be mentioned: (1) The escape of blood into the surrounding cellular (or connective) tissue, giving rise to a swelling called *Thrombus*, which, if it does not rapidly become absorbed, should be emptied by the lancet. This is due to a want of coincidence between the wound in the integument and in the coats of the vein. (2) Phlebitis, which generally arises from the use of an unclean

lancet. (3) Varicose aneurism and (4) aneurismal varix, both of which may be included under the term arterio-venous aneurism, since in each case there is an aneurismal dilatation of an artery communicating with a vein; while they differ in this respect, that varicose aneurism is said to exist when an artery has been punctured through a vein (in this case, the brachial artery through the median-basilic vein), and a false or traumatic aneurism, composed of lymph that was effused between the vessels, has formed between them, and opens into both; while aneurismal varix is similarly produced, but the two vessels adhere together, the communication between them remaining permanent. These diseases often have such a tendency to remain stationary that no interference is necessary; occasionally, however, very serious surgical treatment is required.

In children, and occasionally in others, where the veins of the arm are small and undefined, blood is drawn from the external jugular veins. As this operation would only be performed by a surgeon, it is unnecessary to describe it; and we will merely remark, that as the entrance of air into the vein during the operation, or until the orifice of the vein has been closed, would cause instant death, this vein should only be opened in extreme cases. We have no space to notice at any length the general results of bleeding, or the much disputed question, whether venesection should not be discarded from our list of operations, because no rational doubt can be entertained that, although, until a quarter of a century ago, or later, there was a most unnecessary and probably hurtful effusion of blood, venesection, in properly selected cases, is one of the most valuable remedies.

VENETIAN STYLE of architecture. This term is applied to the particular phase of the renaissance developed in Venice. Under the head ITALIAN ARCHITECTURE, the peculiarities of the various schools of Italian architecture are pointed out. The Venetian is the most picturesque and ornate, as compared with the styles of Rome and Florence. "Venetian-Gothic" indicates the peculiar phase of that style so common in Venice and the north of Italy, and chiefly applied to domestic architecture. See GOTHIC ARCHITECTURE.

VENEZUE'LA, a republic in the n.w. of South America, bounded on the n. by the Caribbean sea, on the w. by the United States of Colombia (New Granada), on the s. by Brazil, and on the e. by British Guiana. The country has been variously subdivided, but in 1881 it was formed into 8 states, a federal district, 2 national settlements, and 8 territories. The area is estimated at 593,943 sq. m., with a population, according to the census of 1891, of 2,323,527. This area, however, is based on the official estimates of the Venezuelan government, and includes the territory which has been claimed by Great Britain, and for many years has been a cause of dispute between the two countries. The British claims applied to the territories of Delta and Yuruari, including about one-third of the former and over half of the latter. The prevailing element in the population consists of the descendants of Spaniards, but they have mingled with the natives, and are largely of Indian blood. The Indians, in 1890, numbered about 326,000, of whom the majority are civilized, and 66,000 are independent. The capital is Caracas, with a population in 1891 of 72,429. Other important cities are Valencia, Maracaibo, and Barquisimeto. The coastline, extending from e. to w.—from the delta of the Orinoco to the boundary of the United States of Colombia—is 1584 m. in length. The most easterly part of the coast-line, 150 m. in length, and formed mostly by the delta, is washed by the Atlantic, and is very low. The waters of the gulf of Paria beat upon bold and rocky shores. The remainder of the coast-line, including the north shore of the peninsula of Paria, is washed by the Caribbean sea, and the coast, for the most part low and marshy, is sometimes precipitous, the mountains rising like a wall from the water's edge. With trifling exceptions, the country is abundantly watered. Its great river is the Orinoco, which drains by far the greatest part of it, and the course of which is almost wholly within its boundaries. The other greater rivers of Venezuela are affluents of the Orinoco (q.v.). Numerous streams, small in comparison with the great rivers, flow n. into the Caribbean sea and the lake of Maracaybo (q.v.), which is by far the largest lake in the country. The Andes enter Venezuela from the w., and divide into two branches, the first of which runs n. toward the coast, under the names of the Sierra de Perija and the Montes de Oca, but rise no higher than 4200 ft.; while the other branch, running in a n.e. direction, terminates near the coast, in long. 68° 30′ w., and attains a much greater elevation. That part of the n.e. branch of the Andes called the Sierra Nevada de Merida, and situated about 100 m. s. of lake Maracaybo, contains the only mountain that rises above the line of perpetual snow, and the two peaks of which are 15,342 and 15,310 ft. high respectively, the loftiest in the country. South and s.e. of the Orinoco are the most mountainous districts of Venezuela. They form a vast, confused, and mostly unexplored region, but none of these mountains rise to the height of the main peaks of the Andes. The country embraces vast table-lands, known under the names of *llanos*, *paramos*, *mesas*, and *punos*. There are extensive low, marshy tracts along the coasts and the lake and river banks, which, however, are abundantly fertile during the dry season. For the most part, the soil of the country is fertile. In the mountainous district in the s.e. there are great tracts well suited for the production of grain. The warmest tracts are the palm-lands; and the sago-palm, cocoa-palm, and others, grow here to a most colossal size, and yield most valuable products. Among the forest trees are the mahogany, satin-wood, rosewood, black and white ebony, and caoutchouc; and there are forests of the cinchona or Peruvian-bark tree. The cocoa and coffee trees, sugar-cane, indigo, and cotton plants are cultivated. Vegetables in great variety are

raised, and tobacco is a profitable crop. Among the wild animals are the puma, ounce, and wild-cat; the jaguar is now becoming rare. The alligator, crocodile, boa-constrictor, and rattlesnake are found. The inhabitants are made up of whites of Spanish extraction; Indians, who are docile and industrious, and are the miners, agriculturists, and manufacturers of the country; some negroes and mixed races. Agriculture is the chief occupation of the people, and the chief products raised are sugar-cane, cocoa, coffee, cereals, etc., in the more temperate parts of the country, and caoutchouc, copaiba, vanilla and tonca beans, and other tropical products in the hot districts. Cattle are also raised in large numbers, finding good pasturage in the great llanos. Sheep, goats, swine, horses, mules, and asses are also reared. The mineral wealth of Venezuela is considerable. Gold occurs in several parts of the country, but chiefly in the Yuruari territory. Silver, copper, and tin are also found, and a considerable revenue is derived from the salt mines under government administration. In 1891 hardly more than a quarter of the land was in private hands. All the rest being without lawful owners was considered public, and managed by the government. The chief trade of the country is with Great Britain, the United States, West Indies, France, Germany, and Colombia. The exports consist chiefly of coffee, cocoa, hides and skins, caoutchouc, timber and cocoanuts, and the imports of coal, manufactured goods, and hardware. There has also been, since the opening up of the mines in the Yuruari territory, a considerable exportation of gold. Internal trade is hindered by the lack of railway communications, but since 1883 there has been considerable improvement in this respect. In 1895 there were only 406 miles of railway open for traffic, but in 1896 and 1897 great activity was shown in railway construction, and the mileage was considerably increased. The monetary unit is the silver bolivar, which is divided into one hundred parts or centesimos, and is equivalent to about 20 cents in United States currency, but while gold must be accepted in any quantity in the payment of debts the acceptance of silver is compulsory only to certain limited amounts. The religion of the country is Roman Catholic, but other forms of faith are tolerated. By the law of 1870 education was made free and compulsory. The form of government is republican, modeled on that of the United States.

History.—The e. coast of Venezuela was discovered by Columbus in 1498; Ojeda and Vespucci followed in 1499, and entering lake Maracaybo, they found an Indian village constructed on piles, to prevent the evil effects of inundation, and they named the place Venezuela, or Little Venice, a name which afterward spread to the whole country. The first settlement was made at Cumana in 1520, by the Spaniards; and Venezuela remained subject to Spain till it claimed independence in 1811. It then returned to allegiance to Spain, but again revolted in 1813, and, forming with New Granada and Ecuador the Republic of Colombia, was declared independent in 1819. In 1830 the states separated. See Colombia. The history of Venezuela has been turbulent; frequent resolutions have disturbed the peace, and presidents have often assumed dictatorial power. During Crespo's presidency the country enjoyed several years of peace, although for a time the boundary dispute with Great Britain threatened to have serious results. This dispute originated in the early part of the century. Great Britain, on acquiring Guiana from the Dutch, became heir to the Dutch claims, to the disputed lands in Delta and Yuruari. The Venezuelans on the other hand succeeded to the territorial claims of Spain when they secured their independence in 1821. After long disputes an attempt was made to compromise on the Schomburgk line in 1841, but Venezuela refused. In 1844, the British offer to accept the mouth of the Maroco river as the dividing point on the coast was declined, and an agreement, entered into in 1850, that the territory could not be occupied, was not maintained by the two countries. The British government in 1881 made another attempt to compromise on a line including territory to the west of the Schomburgk line. Negotiations continued, but, in 1887, diplomatic relations between the two countries were suspended. A few years later the British government gave out that it would insist on the Schomburgk line. At the time when the dispute was at its height, the United States, which had previously offered its intervention, again proposed that the matter should be settled by arbitration. After much discussion and considerable excitement, the proposal of the United States was adopted, and a commission was formed of two members for Great Britain and two for Venezuela, who chose as their president King Oscar of Sweden.

VENIAL SIN (Lat. *veniale*, pardonable, from *venia*, pardon), a term used, chiefly in Roman Catholic theology, to denote the less heinous class of offenses against the law of God. Roman Catholic divines infer from many passages of Scripture that there are various grades of guilt in the culpable actions of man, and that these varieties of guilt involve a corresponding variation in the liability to punishment which is thereby entailed. Lowest in the scale of imputability is the class of offenses known as venial, and by this name distinguished from those which are called mortal. Much difference of opinion exists even among Catholics themselves as to the nature and origin of this distinction. Some ancient writers explained mortal sins as being offenses against a *precept*, whereas venial sins are but violations of a *counsel*. This explanation, however, is now universally rejected; and it is held that sin, of its very essence, whether mortal or venial, supposes the violation of a *law* or precept. Another explanation of the difference declares mortal sin to be that which deprives the soul of sanctifying grace; whereas venial sin only weakens and diminishes, but does not utterly extinguish sanctifying grace in the soul.

This is an explanation, however, rather of the effect than of the nature of venial sin; and the more received opinion is that of St. Thomas Aquinas, who explains mortal sin to be that which of itself subverts *the end* of the law; whereas venial sin but diverts it in a greater or less degree from that to which God intended that it should be directed. Catholics, while insisting on this distinction, are careful to explain that venial sin, although absolutely pardonable, is not to be supposed to be easily pardonable. They hold that it is of its own nature a great "deordination," and that it may and does entail a heavy liability to punishment, although not to the eternal punishment of hell, which is reserved for mortal sin. Sins may be venial either objectively or subjectively; objectively, when the "object" of the law, or what is technically called the "matter" of the sin, is light or trivial; as in the case of a petty theft, a slight departure from truth, or a passing ebullition of impatience or anger; subjectively, when, even though the "matter" or "object" is grave, there is but imperfect advertence, or not full consent, on the part of the subject or agent; as in the case even of a grievous injury done without full knowledge or intention on the part of the agent, or without full and deliberate consent. The degree of culpability in each case is supposed to depend on the objective or subjective qualification of the act. Catholics hold that persons dying in a state of venial sin are not excluded forever from heaven; but that, since nothing unholy, even though in a minor degree, can approach God, the soul departing from life so stained with venial sin, is compelled to undergo a purification in purgatory (q.v.), which they conceive to be of greater or less severity and duration according to the degree of culpability. Some of these writers teach that even venial sins involve punishment of extreme severity; and all expressly declare that it is never lawful, under any circumstances, to commit the smallest venial sin, even for the purpose of compassing a good and holy object.

Protestants reject the whole doctrine of *mortal* and *venial* sins. They regard all sins as, in one sense, *mortal*, i.e., as exposing the sinner to "the wrath and curse of God, both in this world and that which is to come;" but all sins of the believer are expiated by the blood of Christ, so that there remains no penalty to be paid, either by penances in this world, or by sufferings after death. The very notion of venial sins appears to them to make light of the law of God, while that of the expiation of venial sins by the sufferings of the sinner himself, is inconsistent with their doctrine of justification.

VENICE, a province in n.e. Italy, bordering on the Adriatic and adjoining Treviso, Udine, Padua, and Rovigo; drained by the Adige, Brenta, and Piare rivers; pop. '95, (est.) 3,080,153; 9476 sq. m. Capital, Venice.

VENICE, a fortified city of northern Italy, one of the noblest, most famous, and singular cities in the world, is built upon a crowded cluster of 118 islets, in the lagoon of the same name, on the n. w. fringe of the Adriatic sea, 23 m. e. of Padua by the Milan and Venice railway; lat. 45° 26′ n., long. 12° 20′ east. The lagoon of Venice is banked off from the Adriatic by a long, narrow sand-bank, extending s.w. from the mouth of the Piave to that of the Adige, and divided into a number of islands by narrow sea-passages, six in number. Formerly, the chief of these entrances into the lagoon was the Porto di Lido, through which all the great merchantmen of the republic passed direct into the city, and which is still frequented by small vessels, and by the Trieste steamers. The Porto di Malamocco, between the island of the same name on the s., and that of Lido on the n., is now the deepest channel into the lagoon. Inside of this sand-bank, and between it and the mainland, which is from three to five m. distant, is the lagoon—a sheet of shallow water, navigable for vessels of very light draught, except where channels have been formed naturally by rivers, and artificially maintained. In some parts of this marshy, sea-covered plain, islets have—by the action of currents and otherwise—become consolidated into ground firm enough to be built upon, and fruitful enough to be cultivated; and in the midst of a crowded cluster of such islets, amounting in number to between 70 and 80, the city of Venice is built. In the vicinity of Venice, the ebbing tide (the difference between high and low water is only between 2 and 3 ft.) lays bare nearly everywhere a great plain of calcareous mud, laced, however, by an intricate network of narrow channels, from which the sea never retires; while at high water the whole surface is covered by the sea to the depth of from 1 to 1½ feet. The chief of the islands upon which Venice is built is called *Isola de Rialto* (i.e., *rivo alto*), or Island of the Deep Stream. The islands, in many places only shoals, afford no good foundations for buildings; and the city, for the most part, is built upon artificial foundations of piles or stone. The fact that this city of marble palaces seems to rise vision-like from the unsubstantial sea, is sufficient to render its aspect at all times more or less fascinating; but in summer and autumn, the seasons of the highest tides, when the Grand Place of St. Mark's is partially flooded, and when the image of each palace is doubled by reflection in that "green pavement, which every breeze breaks into new fantasies of rich tesselation," the city is indeed marvelously beautiful. The Canalazzo, or Grand Canal—its tortuous course through the city being in the form of the letter S reversed—divides Venice into two unequal parts, and is the main thoroughfare for traffic or pleasure. But the city is sub-divided by 157 smaller canals,

or *rii*, as they are termed. These are the water-streets of Venice, by means of which passengers can be conveyed to any quarter, for here the canal is the street, and the gondola (q.v.) is the cab or carriage. Access can also be had to all parts of the town by land —across the canals by bridges, and among the houses by narrow lanes called *calli*. There are in all 306 public bridges, and of these, three cross the Grand Canal—the Rialto, a stone structure, and the most famous; and two iron bridges. The piazza or square of St. Mark's is the great center of business and amusement, and the locality most frequently visited by travelers in Venice. It is 576 ft. in length, 269 ft. in greatest width, and 185 ft. in least width. The e. side of this square is occupied by St. Mark's church. The first church of St. Mark's was built in 830, but was destroyed by fire in 976. It was rebuilt in 1071, and consecrated before the close of the 11th century. The edifice is Byzantine, with Gothic additions of the 15th c., and renaissance alterations of the 17th century. It became the cathedral and seat of the patriarch in 1807. The plan of St. Mark's is the Greek cross. Above the doorway are the four famous horses which Marino Zeno brought from Constantinople in 1204, which were carried away by Napoleon in 1797 to Paris, and restored to Venice in 1815. A great dome rises over the intersection of the lines of the cross; and over the transepts, other domes arise. The carved work, which is very profuse, is of the most exquisite description; and the building is perfect as an example of the delicately-colored architecture of the east. The structure is of brick, incrusted with richly-colored marbles. To the right of this beautiful edifice is the *Torre dell' Orologio* (built in 1496), with a splendid dial in gold and azure, and very complex and ingenious movements. The n. side of the square is almost entirely taken up by the *Procuratie Vecchie*, built in 1517, for the accommodation of the procurators or trustees of San Marco, who had the care of the edifice, the management of its property, etc. Facing the procuratie Vecchie, and on the s. side of the square, are the buildings of the *Procuratie Nuove*, which are connected with a façade, which forms the w. side of the square, and the two buildings constitute the *Palazzo Imperiale*. Leading s. from the piazza is the piazzetta, or little square; and near the point where it makes an angle with the great square, is the Campanile, or bell tower, of St. Mark, placed at some distance in front of the building to which it belongs. It was founded in 888, and rebuilt in 1329, is 322 ft. high, 42 ft. wide at the base, and is surmounted by an angel, which serves as a weather-cock, and is said to be 16 ft. high. On the w. side of the piazzetta are the old library and the mint, the former now forming a part of the Palazzo Imperiale. At the s. of the piazzetta are the two famous red granite columns of Venice, one of which is surmounted by a figure of St. Theodore, the patron saint of the republic till St. Mark supplanted him; the other covered by the lion of St. Mark. On the e. side of the piazzetta stands the palazzo ducale or doge's palace. The first palace reared on the site of the present one was built in 813, and though frequently enlarged, rebuilt, and redecorated, it retained throughout the character of a Byzantine structure. In the year 1301, its architectural character began to change; and from that time till 1423, all the rebuilding and enlarging were executed in Gothic. After the date 1423, there are no buildings in Venetian architecture, properly so called; and the alterations made in the ducal palace after that time, as well as the palaces subsequently built, which took their style of architecture from the doge's palace, were in renaissance, and like almost all the architecture now to be seen in Venice, "of immeasurably inferior spirit in the workmanship" to that native style which flourished with the republic, and decayed with it. Starting from the landing-place of St. Mark's at the e. extremity of the Grand Canal, and proceeding w., a great number of palaces are passed. In former times, these palaces, or the magnificent buildings which occupied the same sites, were the warehouses and places of business of the great merchant-princes, most of whom possessed mansions in the suburbs, i.e., on some neighboring island, which afforded more privacy than could be found in the city itself. A few of these are worthy of mention. Among them are the *Palazzo Giustiniani*, now the *Albergo dell' Europa*, perhaps the best hotel in Venice; the *Palazzo Contarini Fasan*, a beautiful specimen of the richest Venetian Gothic of the 14th c.; on the left bank, the *Palazzo Pisani a S. Paolo*, in arabesque Gothic of the beginning of the 15th c.; further on, on the right, the *Palazzo Loredan*, the *Ca' d'Oro*, a building of the 15th c., in the oriental style, restored by Mlle. Taglioni, the celebrated dancer. The bridge of the Rialto crossing the Grand Canal consists of one arch, the span of which is 74 ft., and the height from the water 32 feet. The width is 90 ft., and the bridge is divided into three streets—the middle one 21 ft. wide—and two rows of shops. The Bridge of Sighs (*Ponte dei Sospiri*) stretches across the canal called the Rio Palazzo, and communicates between prisons on the e., and the Doge's palace on the w. bank of the canal. It is a covered gallery; and prisoners, when led to execution, passed from their cells across this gallery to the palace, to hear sentence of death passed upon them, and then were conducted to the scene of death between the red columns. The churches of Venice are, as a rule, fine edifices, and of various styles. The styles are chiefly, first, Venetian Gothic, massive and solemn; second, Lombard; third, classical, i.e., Italian; fourth, decorated Italian. Among the chief churches after St. Mark's are those of the *Frari*, with a colossal monument of Titian, a number of excellent pictures, etc.; and the church of *S. Giacomo di Rialto*, at the foot of the bridge of the same name, occupies the site of the first church erected in Venice in 421. But of the multitude of churches, a great many, though of pleasing proportions, are in the later and degraded

styles of architecture. The fine art *academia* is located in the ancient convent of *La Carità*, was formed in 1807 by Napoleon, and consists of several schools, and has the finest collection of pictures of the Venetian school, including works by Titian, Tintoretto, Bonifacio, Giovanni Bellini, Paolo Veronese, and many other masters. Specimens of the works of these artists are also to be found in many of the palaces and churches of the city. There are several theaters, the chief of which is *la Fenice*. Fresh water, formerly, and even still to some extent, obtained at great expense, and of bad quality, from the mainland, or kept in cisterns, is now obtained by means of a number of artesian wells, sunk in 1847, at the expense of the municipality. The library of St. Mark's contains many valuable documents. Many writers have led to misconception by omitting to note the fact, that the Venice of to-day is by no means the same city as the Venice of earlier and more famous days. On this subject, it will be of interest to quote the following from Ruskin's *Stones of Venice* (vol. ii., pp. 4, 5): "The Venice of modern fiction and drama is a thing of yesterday, a mere efflorescence of decay, a stage dream, which the first ray of daylight must dissipate into dust. No prisoner whose name is worth remembering, or whose sorrows deserved sympathy, ever crossed that 'Bridge of Sighs,' which is the center of the Byronic ideal of Venice; no great merchant of Venice ever saw that Rialto, under which the traveler now passes with breathless interest." Among the chief manufactories of Venice are the glass-works, in which magnificent mirrors, artificial pearls, gems, colored beads, etc., are made, and which employ 4500 people. Jewelry, especially chains of the precious metals, gold and silver stuffs, silks, laces, velvets, soap, earthenware, wax-candles, etc., are also manufactured; and sugar-refining and ship-building are carried on. The trade of Venice greatly declined for several years previous to 1866. This decline, however, being due to the uncertainty and unsatisfactory political state of the Venetian provinces, there have been signs of revival since the incorporation of Venice with Italy. The goods exported consist in the main of grain, fruits, fish, and wine, while those imported consist chiefly of cotton, coals, coffee, colonial produce, woolen and linen yarns, and manufactured goods. In 1895, 3549 vessels of 1,197,307 tonnage entered, and 3444 of 1,209,721 cleared the port of Venice. Pop. (1881) of town, 129,276; of commune, 132,826. Pop. cummune '95, 153,900.

History.—Previously to the Roman conquest, we know almost nothing of the history of Venetia; but, at the time when that event took place, we know that this region was inhabited by two nations, the Veneti and the Carni. The Veneti, from whom the district derived its name, occupied the tract between the Plavis (Piave) on the n., and the Athesis (Adige) on the south. The origin and affinities of this people are unknown, and almost the first thing ascertained concerning them is that, in the very earliest times of which we have any record, we find them a commercial rather than a warlike community, carrying on a trade in amber, which they brought from the shores of the Baltic, and sold to the merchants of Phenecia and Greece. Under the Roman empire, the province became opulent and flourishing; and besides its capital, Aquileia, which rose to be one of the most prosperous cities in Italy, it contained also the powerful and wealthy provincial cities, Patavium (Padua) and Verona, and numerous important towns. But before the close of the empire, the early prosperity of this province was swept away by the Huns under Attila, who, in 452, raised Aquileia to the ground, and devastated the cities of Concordia, Altinum, Patavium, Vicentia, Verona, and other cities of the province. Many of the inhabitants of these cities, driven from their ruined homes, sought shelter in the marshy lagoons, in a position too miserable to provoke the ambition of the conquerors, and defended from invasion from the main-land by the wide tract of muddy shallows which intervened between it and the actual shore, and secured against attack by sea by the shallowness of the water and the intricacy of the sea-passages. Of the cluster of islands upon which ancient Venice stood, the principal were Grado Bibione, Caorlo, Heraclia, Equilo, Torcello, Murano, Rialto, Malamocco, Pelestrina, Brondolo, San Nicolo, Chioggia (Piccola and Grande), Amiano, Constanziaco, Olivolo, and Spinalunga. To Rialto and to Malamocco, the refugees from Padua resorted. The name of the province they had left was afterward transferred to the cluster of the islands of the lagoon—the new settlement being commonly known, at least as early as the 8th c., as Venezia, or as we have it, Venice. Protected by the peculiar position of the islands in which they had found refuge, the early settlers devoted themselves to the pursuits for which their situation offered the greatest facilities—fishing and the manufacture of salt. Houses began to cluster thickly on the Rialto; and when, in 568, Padua was sacked by the Lombards, many of its inhabitants emigrated to that infant colony which their ancestors had helped to found. The first form of government of the island-commonwealth was republican, administered by a consular triumvirate; but in 457 the consuls were superceded by tribunes who, elected annually, and varying in number at different times from 1 to 12, administered the government for 240 years. But during this period, although the young republic progressed in wealth and population, it did little to increase its political importance. Society was divided into factions by the ambition of the rival tribunes, and variety of interests rendered united action in warfare impossible. With the purpose of remedying the many evils of the government, Christofero, patriarch of Grado, in 697, laid before the arengo—the periodical convention of the whole adult male population—a scheme in which he proposed that the tribunes should abdicate sovereign

power, and that a magistrate, with the title of duke or doge, in whom should be vested undivided authority in civic, ecclesiastical, and military matters, should be placed over them. The proposition was received with much favor, and the election to the office fell upon Paolo Luca Anafesto, who was invested by the metropolitan with his insignia of office, a crown of gold, and a scepter of ivory, March, 697. Anafesto remained at the head of affairs till his death in 717, and under his rule the position of the republic greatly improved. Civil discords were in great measure stilled, and the Venetian territory was increased by the acquisition of a strip of the main-land, obtained by treaty from the king of the Lombards. Under Orso, the third doge (720–737); the Venetians entered upon that career of enterprise in which their prudence and their valor were always equally conspicuous, and which they continued to pursue to the last. In 735 the Lombards seized Ravenna, compelling the exarch (q.v.) to seek shelter in the lagoon, and implore the republic to lend her aid in reacquiring the lost territory. Still considering themselves as nominally subject to the eastern emperor, besides being anxious, in the interests of their commerce, of securing the alliance of Constantinople, and of obtaining the freedom of the seas of the eastern empire, the Venetians supplied the required assistance, and reinstated the exarch in his vice-royalty. The services of the doge on this occasion were rewarded by the Byzantine court with the honorary title of Hypatos, or imperial consul. The common punishment among the Venetians for tyranny was putting out the eyes, and the reigns of several of the doges at this time are but periods of tyranny and excess on the part of the ruler, terminated by exoculation or assassination by the people. By a treaty concluded in 803 between Charlemagne and the emperor of the east, it was stipulated that the maritime towns of Istria and Dalmatia should be considered an integral portion of the eastern empire. This stipulation was adhered to till the year 808, when the aggressive policy of Charlemagne and of his son Pepin, now king of Italy, prompted Nicephorus, the emperor of the east, to dispatch a squadron to the Adriatic, and to seek the alliance of the Venetians; and as the latter perceived that they had much more to gain from the friendship of the court of Constantinople—the key to the rich waters of the east—than from that of Charlemagne, the alliance was soon cemented. War immediately broke out, and Venice was invaded by king Pepin, who took a number of the islands without meeting any resistance—the inhabitants having all been transferred to the central island, Rialto. The French advanced to the island of Albiola, when, to their dismay, they found that the tide had been ebbing, and that their vessels were stranded in these shallows. The whole French squadron now fell an easy prey to the swift-moving galleys of the Venetians, and such of the enemy as escaped being drowned were massacred by the relentless islanders (809). This struggle, called the battle of Albiola, was conducted on the part of the republic by Angelo Badoer, tribune of the island of Rialto, who was raised to the rank of doge, and transferred the seat of government to Rialto—the island of Heraclia and others having previously enjoyed that honor. In his reign, also, connection was established between Rialto and all the circumjacent islands, by means of wooden bridges, and the cluster thus united now formally took the name Venezia (Venice), although it commonly received that name early in the previous century. The year 827 is memorable as that in which, according to tradition, the body of St. Mark was transferred to Venice from Alexandria. "That the Venetians possessed themselves of his body in the 9th c., there appears," says Ruskin, "no sufficient reason to doubt;" and however we may regard this story, it cannot be denied that the belief in it by the Venetians and others attracted crowds of pious pilgrims to Rialto, and thus increased the traffic and prestige of the port; while the Venetians adopted St. Mark as their patron saint; and their war cry, "Viva San Marco!" inspired their courage in many a fight, both on sea and land. For many years after this date the history of Venice is marked by no event of special note; but the naval importance, the commerce and wealth, and refinement of the republic, increased year by year. Doge Orseolo II. (991–1008) greatly extended the trade of the republic by establishing commercial relations between it and the empires both of the east and west, the Crimea, Syria, Egypt, Tartary, Tunis, etc.; and under his rule, the territory of Venice, which, until lately, comprised only the islands of the lagoon, and a narrow slip of territory on the mainland, was increased by further acquisitions on the mainland, and by the addition of the sea-boards of Dalmatia and Istria, which he annexed in 998. In 1085 the provinces of Dalmatia and Croatia were formally ceded to Venice by the emperor of the east; and at the same time the emperor exempted the Venetian traders in all parts of the empire, excepting in Cyprus, Candia, and Megalopolis, from all duties and imposts whatever. In 1099 Venice sent forth a fleet of 207 vessels of all sail to the succor of Godfrey de Bouillon and his companions of the first crusade. The defeat of a hostile Pisan fleet employed by the eastern emperor, Alexius Comnenus, and the capture of 20 of the vessels, and the obtaining of the body of St. Nicholas at the island of Myra, were the chief incidents of this expedition, which partook more of the nature of a predatory cruise than of a pilgrimage and crusade. But it is noticeable that in all the cases in which Venice joined the crusaders, the chief motive seems rather to have been to monopolize the maritime department of all these movements, and to extend her commercial relations, than to secure the holy sepulcher in Christian possession. The great fires of 1106, which, besides destroying the island city of Malamocco, reduced 30 churches and vast numbers of private dwellings in Venice to ashes, were indirectly the

cause of great improvements in the architecture of the city; for previously to this event, the dwellings of the Venetians were almost all built of wood; but after it, the material used was always either stone or marble obtained from Italy, Istria, or Dalmatia, in all of which it is found in abundance. In 1111 the doge Faliero sent forth 100 galleys to aid Baldwin I., the successor of Godfrey de Bouillon, in the conquest of such Syrian ports as remained in the hands of the Mussulmans; and for the assistance thus rendered, the Venetians obtained the right to hold in possession a church, street, mill, bakery, bath, etc., and to be represented by a local magistrate in each of the oriental possessions of christendom—rights of the very greatest importance to a trading community. In 1123 a fleet sent to succor the Christians in Palestine, and led by the doge Michieli, distinguished itself by gaining a magnificent victory over an Egyptian fleet, and by the capture of ten Turkish galleons richly freighted. In the same year, the Venetians and their allies, the Christians in Palestine, reduced the almost impregnable city of Tyre, after a siege of four and a half months. In 1122 a decree was passed by Johannes Comnenus, the eastern emperor, commanding the Venetian residents at Constantinople and the other Greek ports to quit the imperial dominions, and declaring the suspension of all intercourse between the two powers. The islanders thus saw the most profitable branch of their commerce threatened with extinction; and resolved to make reprisals, they launched a fleet in 1123, and in that and the following year they inflicted a terrible punishment on the empire, capturing Rhodes, and investing and sacking Andros, Samos, etc., all the Ionian islands, a portion of the Peloponnesus, etc. Further, this brilliant expedition was not brought to a close until all the Dalmatian fiefs, stirred to insurrection by Stephen, king of Hungary, were again reduced to submission. The Venetians were prominent members of the league of Lombardy against the German emperor; and in 1177 won a splendid victory over the Ghibellines, headed by Otho, son of Frederick Barbarossa, in defense of Pope Alexander III., who had appealed for protection to the republic. Otho's squadron numbered 75 sail, chiefly drawn from the ports of Genoa and Ancona; the Venetian force consisted of 34 large galleys; and the victory they gained influenced the pope to show his gratitude by presenting the doge Ziani with a ring, with which he commanded him to wed the Adriatic, that posterity might know that the sea was subject to Venice "as a bride is to her husband;" and it is recorded that in this year the pompous ceremony of the "marriage" was celebrated for the first time. The result of the naval battle of Saboro was that Frederick agreed to a congress, which took place at Venice in 1177. On the occasion of this congress, when the pope, the doge, and other dignitaries were assembled in the palace of St. Mark's, Frederick approaching the throne on which Alexander III. was sitting, and prostrating himself, allowed the pope to plant his foot upon his neck. The congress of Venice restored peace between the empire and Lombardy and Sicily. The doge Ziani died in 1178. He did much to improve the architecture of the city, especially of the square of St. Mark. Of the three lofty red granite pillars which he is believed to have brought from the island of Scio, two adorn the portico of St. Mark's—the third fell overboard and was lost in the attempt to land it. In Oct., 1202 the expedition known as the fourth crusade set out from Venice, in Venetian vessels, under the command of the venerable doge, Arrigo Dandolo; it did not, however, reach Palestine, but directed its force against the Byzantine empire, which fell into the hands of the so-called crusaders, April 1204. See Dandolo. On the division of the conquests of this expedition, Venice received the Morea, the Illyric isles, a large portion of Thessaly, the Sporades, the Cyclades, the cities of Adrianople, Trajanople, Dedymotichos, and Durazzo, the province of Servia, and the coasts of the Hellespont. A fourth part of Constantinople was set apart as a quarter where the Venetians might reside, under the protection of their own laws; and all restrictions as to trade were abolished. Venice was now in possession of the fairest portions of the lower empire, and she had long been undisputed mistress of the seas. As she increased in power, she also increased in magnificence; and her nobles, having no lands in which they might employ their wealth, lavished immense sums upon their palaces, their pictures, decorations, and costly garments. Her palaces were decorated with the treasures and spoils of the east, and a school of artists arose, who found noble subjects for their pencils in the deeds of Faliero, Polani, Ziani, and the Dandoli. Her noblemen were now the most opulent in Europe, and travel and refinement had made them also the most polished. The most notable events in the history of Venice during the 13th c. are her wars with Genoa, in which her hitherto unfailing good fortune deserted her, and the star of Dandolo succumbed to that of Doria at the desperate battle of Corzuola, from which conflict the Venetians could only retire with 12 out of 96 of their galleys, the others being taken or burned; the truce effected between Venice and Palæologus, the emperor of the east, in 1268; the electoral reforms by which, after a complex and often repeated process of election and reduction by lot, the forty-one members were chosen who formed the electoral college, and of whom it was necessary that the doge-elect should obtain at least the votes of twenty-five. In 1289 the inquisition was formally established in Venice, but this institution was rendered subject to so many limitations by the government of the republic, that it remained comparatively harmless. In 1310 a conspiracy was formed for the correction of abuses that had crept into the constitution, and for the punishment of actual and fancied crimes. Among the conspirators were members of many of the noblest families of Venice. This

conspiracy, known as the Quirini-Tiepolo conspiracy, proved abortive; but among other reforms to which it gave rise was the formation of the famous council of ten, who caused themselves to be declared a permanent assembly in 1335. In 1343, Andrea Dandolo, born in the year of the Quirini-Tiepolo conspiracy, a most accomplished scholar and statesman, was raised to the dogate. His *Venetian Annals*, remarkable for their precision and accuracy, place their author in the first rank of mediæval historians. In 1348, the lagoon was visited by an earthquake, accompanied by unusually high and destructive tides. These misfortunes were followed in the same year by a most frightful visitation of plague; and in the course of the six or seven months during which the epidemic raged, two-fifths of the population of the city perished, and fifty patrician families became extinct. The middle of the 14th c. is remarkable for the famous conspiracy headed by the doge Marino Faliero (see FALIERI), and for a war with Hungary, in which Venice lost Dalmatia. The commercial rivalry of Venice and Genoa in the east led to a war in 1352, in which the Venetians were defeated (Feb. 13, 1352) by Paganino Doria in the straits of the Bosporus; and though they recovered their lost laurels in a battle (Aug. 29, 1353) off the Sardinian coast, their fleet was totally destroyed by Doria, in the gulf of Sapinoza, Nov. 3, 1354, and they were forced to make peace in the following May. In 1378, the Venetians interfered in the quarrel between the Genoese and Cypriots, and their fleet vanquished that of the Genoese before Antium (July), in revenge for which the Venetian fleet was almost annihilated off Pola (May, 1379), and Pietro Doria, advancing upon Venice itself, seized the island of Chioggia. But the courage of the Venetians was nothing weakened by their dreadful reverses, and they soon changed the aspect of affairs by becoming in turn the besiegers themselves, blockading the enemy in Chioggia, and, after reducing him to the brink of starvation, accepting an unconditional surrender, June, 1380. In 1396 Genoa, the oldest and most harassing foe of the republic, ceased to have separate existence as an enemy, for in that year she placed herself under the dominion of the king of France, an arrangement which afforded immeasurable relief to Venice, because, for several reasons, there was now much less chance of a rupture between the two maritime powers. For a number of years after this event, Venice experienced the highest prosperity: a prodigious impulse was given to her trade; her argosies traversed every arm of the ocean; intimate intercourse was kept up with every European country, as well as with Syria, Egypt, and even India, and important articles of Venetian merchandise were the iron of Staffordshire, the tin of Cornwall and Devon, and the wool of Sussex. But no less beneficent than the effects of peace were those of the war which soon broke out between Novello, lord of Padua, and Venice. At the conclusion of this war (1407), Venice found herself in the possession of an empire on the mainland of Italy, the smallest communal section of which equaled their ancient island domain, and of which the principal cities were Vicenza, Verona, Padua, Feltre, and Belluno. With the death of the doge Mocenigo in 1423, a new era in the existence of Venice commences, for now "the central epoch of her life was past, the decay had already begun." During the next thirty years, war was continually waged, chiefly against the dukes of Milan, in the course of which Venice, taking into pay Carmagnola (q.v.) and his bands achieved many a splendid victory, and suffered many a disastrous defeat; and though, on the return of peace (1455), the territory of the republic was materially increased, by the acquisition of Brescia, Bergamo, Treviso, etc., on the mainland, this territory was obtained only after a struggle, enormously expensive in life and treasure, and during the continuance of which the commerce of Venice—the well-spring of its prosperity at all times—began to decline. Mocenigo's last advice to the senate was to avoid war, which was certain to bring destruction on the country, and to prosecute industriously their trade and commerce, and cultivate the arts of peace. The rejection of this advice, combined with the narrow-minded selfish policy always pursued by the Venetians in the contests among the Italian states, was the prominent cause of its decline. The same fatal warlike policy was pursued throughout the 15th c.; and the whole of the 16th c. was employed by them in repairing the disasters which the league of Cambrai had brought upon them. Her policy in the 17th c. was to aid the opponents of her most dangerous neighbor, Austria, by recognizing Henry IV. of France, aiding Bethlem Gabor and Ragotski, the duke of Savoy, against Spain, and the Protestants against the Catholics of the Grisons. From 1646 to 1669, war was carried on between the Venetians and Turks, the latter being, in almost every encounter, severely defeated; though, from the disproportionate strength of the antagonists, they ultimately gained Candia, the object of the war. The discovery of the cape of Good Hope by the Portuguese in 1486, opened up to that nation an ocean-route to India, which was taken advantage of by Vasco da Gama, who rounded the cape on his voyage from Lisbon to Calicut in 1497. The carrying-trade of the world was now no longer, as it had been, in the hands of the Venetians; and the vast commercial activity which sprang up among the western nations of Europe upon the discovery of America clearly showed that the naval superiority of the republic had forever disappeared. But even in spite of these changes of fortune, Venice might still have maintained a respectable mediocrity among maritime states, but for the character of her government, which was conducted by an exclusive oligarchy, in whose hands alone all power and freedom were vested. Long prior to the invasion of the republic by Napoleon in 1796, Venice had become worn out and corrupted; the government of the council of ten had become a reign of terror; its nobles

showed vigor only in the pursuit of pleasure; its peasants, inured to peace, were unequal to war—all the ancient virtue, valor, and hardihood, which had raised a colony of fishermen, "perched like sea-fowl" on a muddy shoal, to be a nation of the first rank, had died out of the state. Napoleon forced Venice to break the neutrality which it meant to maintain in 1796, destroyed its government, and ceded the province to Austria by the treaty of Campo-Formio (q.v.). In 1806, the city of Venice, with the territory of Venetia, was annexed to the kingdom of Italy by the treaty of Presburg (q.v.); but it was transferred to Austria in 1814. In 1866 the city and territory were ceded to and incorporated with the kingdom of Italy.

VENETIA, TERRITORY OF, ceded to Austria in 1815 (see above), formed from that year, along with Lombardy (q.v.), what was called the Lombardo-Venetian kingdom, one of the Austrian crownlands. In 1859 Lombardy was ceded to Italy, but Venetia continued in the possession of the Austrians till 1866, when, as one of the results of the famous "Month's War," it also was ceded to Italy, and is now incorporated with that kingdom. While still in Austrian possession, Venetia was regarded as bounded on the n. by the Austrian crownlands of the Tyrol and Carinthia; on the e. by Görz and Gradisca; on the s. by the Adriatic sea, the river Po, and the duchy of Modena; and on the w. by the river Adige and the Tyrol. The territory of Venetia, ceded to Italy by the treaty of peace, Oct. 3, 1866, has the same frontiers which it had as an Austrian province.

VENI CREATOR SPIRITUS, an ancient and very celebrated hymn of the Roman breviary, which occurs in the offices of the feast of Pentecost, and which is used in many of the most solemn services of the Roman Catholic church. Its author is not known with certainty. On the authority of an ancient life of Notker, it is ascribed to Charlemagne; and Daniel, in his *Thesaurus Hymnologicus*, adopts this opinion; but it seems to be certainly older than the age of Charlemagne; and its correct classical meter, as well as the purity of its language, bespeak an earlier and purer age. Mone makes it highly probable, by intrinsic evidence, that it is the composition of Pope Gregory I. The Veni Creator Spiritus must not be confounded with another hymn to the Holy Ghost, Veni Sancte Spiritus, which somewhat resembles it. The latter belongs not to the breviary, but to the missal, in which it forms a "sequence" in the mass of Pentecost Sunday and Octave. The latter hymn is not in classical meter, but in rhyme; and its language is plainly of a lower age. The author of the Veni Sancte Spiritus is believed to be king Robert of France, to whom several other hymns of the same class are attributed.

VENIRE, or VENIRE FACIAS, in law, a writ to the sheriff of the county, ordering him to choose and summon from the county, and have in court on a day named a certain number of qualified citizens of such county to act as jurors in the court. This was the common law method of summoning a jury, but in many states jurors are drawn by lot from a list of qualified persons made by the proper local authorities; in New England, by the selectmen of the town. The sheriff then summons without a *venire*, which is, however, still used to summon additional jurors.

VENISON. A name originally applied to all game. In Genesis XXVII. 3, Jacob says to Esau: "Now therefore take, I pray thee, thy quiver and thy bow, and go out to the field, and take me some venison," meaning the wild kid. In England the term venison may still be applied to the flesh of the hare and certain birds, as well as to that of the deer. Buck-venison is best from Aug. 1 to Nov. 1; doe-vension from Nov. 1 to Jan. 1. Venison is cut into joints and sold as saddle, haunch, leg, loin, fore-quarter and steak.

VENLO', a small but strongly fortified t. in the Netherlands, province of Limburg, is situated on the right bank of the Maas, 60 m. n.w. of Cologne, and has a safe little haven. The fortifications are very irregular, consisting of a main wall, canal, outworks, three powder-magazines, etc. The town is well built, and stands on elevated ground, surrounded by morasses. Principal buildings are the town-house, the great arsenal, the church of St. Martin, etc. Venlo manufactures cigars, gin, and needles. Pop. '93, 12,154.

VENN, Rev. HENRY, a pious clergyman of the Church of England, was b. at Barnes in Surrey in 1724. Having studied and entered into holy orders—in this respect following the example of his paternal ancestors since the reformation—he was shortly after appointed curate of Clapham. In 1759 he resigned his curacy to become vicar of Huddersfield in Yorkshire, which he left in 1769, on being presented to the rectory of Yelling in Huntingdonshire. He died in the house of his son, John Venn, rector of Clapham, in June, 1797. The memory of his pure life, good example, and earnest preaching was cherished for many years after his death in the places which had benefited by his ministration; and his name is associated with those of John Newton, Thomas Scott, Charles Simeon, and others, as having had considerable influence on the evangelical movement in the church of England. Venn was the author of a book entitled *The Complete Duty of Man*, a sort of development or extension of the *Whole Duty of Man*. His *Life and Correspondence* was published by his grandson, Henry Venn, in 1839.

VENOMOUS BITES AND STINGS. Under this title are considered all wounds inflicted by animals which by their bites or stings introduce poisonous or irritating matter into the bodies of their victims. In this country the subject is of comparatively little importance, since it is very seldom that the bite of our most venomous animal—the adder—is fatal; but in warmer countries it demands the serious attention of the surgeon. Following Mr. Busk, in his article on "Venomous Insects and Reptiles," in Holmes's *System of Surgery*, we shall briefly enumerate the most venomous animals found (1) among the invertebrata, and (2) among the vertebrata.

(1) Among the invertebrata, the most formidable poisonous animals are to be found in the classes *arachnida*, *myriapoda*, and *insecta*. The *scorpions* are characterized by a prolonged jointed abdomen, terminating in a hooked claw, which is perforated, and connected at the base with poison-glands. The larger species, which are restricted to hot countries, by their sting give rise to symptoms of great severity, and occasionally cause death. "The symptoms resemble those produced by the stings of wasps and bees in an aggravated degree, such as acute pain, a general nervous shock attended with numbness, vertigo, occasionally temporary loss of sight, vomiting, etc.; while the local symptoms are swelling, and other signs of acute inflammation, followed, in many cases, by suppuration, sloughing, and their consequences. The remedy which appears to have obtained the greatest repute, is the application of ammonia externally, and its internal administration as a stimulant also; although it is probable that any other diffusible stimulus, combined with opiates, would be equally, if not more efficacious."—Busk, *op. cit.*, p. 921. Several species of *scolopendra*, or *centipedes*, are regarded as highly venomous, and there is no doubt that the bites of some of the larger kinds inhabiting hot countries (especially of *S. morsitans*), give rise to excessively painful consequences, although less severe than those occasioned by the sting of the scorpion. In these animals, the poison is introduced not by a caudal sting, but by perforated curved fangs, connected with the mandibles, where poison glands doubtless exist, though their existence has not been clearly established on anatomical evidence. Although *spiders* have long had a bad reputation for their venomous bites, it is quite certain that (with certain rare and foreign exceptions) their bite inflicts no more than a simple wound. The most ill-famed of the spiders is the tarantula or tarentula (*lycosa tarentula*), a citigrade or running spider, common in south Italy. See TARANTISM. Direct experiments, however, show that the bite of this spider merely causes a slight local irritation. There is a spider inhabiting the island of Elba (*aranea 13-guttata*), which is said to be dangerous and even fatal to men and domestic animals; while the cork-forests of Morocco are said to be infested by an equally formidable spider, which is there known as the *tendevaman*. It would be well if scientific travelers in those countries would obtain more definite information regarding these spiders. Among insects, many inflict more or less troublesome bites, while a comparatively few (and those almost, if not altogether, restricted to the order *hymenoptera*) inflict serious injury by their stings.

In the case of the majority of biting insects, it is very doubtful whether the local discomfort is due to the introduction of poison, or is the consequence of the prolonged mechanical irritation only. In some cases, as in the ants, we know that formic acid (an irritant of great power) is introduced; and considering the prolonged irritation that follows the bites of many small insects, it is probable that there is some special acrid matter in their salivary secretion. This view is further borne out by the fact, that persons who suffer much from the bites of fleas and bugs (and the degree of annoyance varies extremely in different persons), are relieved by the local application of hartshorn, or some other preparation of ammonia. The "tsetse" (*glossinia morsitans*), whose ravages are so graphically described by Dr. Livingstone, does not attack man, but it affords an example of an insect, very little larger than a house-fly, being able to secrete an intense septic poison, which, introduced by its bites, causes certain death to cattle, the sheep, horse, and dog, while it is innocuous not only to man, but to the goat, antelope, ass, and pig, to all wild animals, and to the calf until it is weaned. Another insect, mentioned but not described by the same traveler, produces by its bite vomiting and purging in man. In the case of stinging insects, the stinging instrument consists essentially of two fine and sharp dots, enclosed in a tubular sheath, at the base of which is a poison-sac, whose contents are injected into the wound made by the darts, which are usually serrated or barbed. The consequences of the sting of a bee or wasp are too familiar to require any detailed notice; and the sting of the hornet, a much rarer insect, is of the same nature, but of an aggravated form. The sting of a bee or wasp scarcely ever proves fatal, except the insect is swallowed in a cavity in ripe fruit, or in the act of drinking, and inflicts its sting on the throat. A sting in the fauces usually excites severe and diffuse inflammation, which may extend to the glottis, and thus cause suffocation. The treatment must be prompt, and consist of scarification internally, leeches externally, and possibly tracheotomy. When a large number of any of these insects make a combined attack, the result may be fatal. For the bites and stings of all these animals, the remedy recommended for scorpion-stings must be used; namely, ammonia in some form or other, and probably sal-volatile is the best. Among various domestic remedies for allaying the irritation excited by these stings, are vinegar, oil, spirits, eau-de-cologne, the blue-ball employed by washerwomen, consisting of indigo, etc. If possible, the sting

should be extracted by bringing it to view by pressure over the wound with a watch-key, and then seizing it by small forceps.

(2) Among the vertebrata, the only animals capable of inflicting poisoned wounds are the ophidian reptiles or snakes. As the description of the mechanism of the poison-fangs of venomous snakes is sufficiently given in the article SERPENTS, we may pass on to the subject of the nature of the *venom* and its effects. The venom is described, when fresh, as a transparent, yellowish or greenish, somewhat viscid, neutral fluid, much resembling saliva in its physical character, and exhibiting no obvious indication of its virulent nature. According to Prince Lucien Bonaparte, it contains, in addition to albuminous or mucous and fatty matters and the usual salts, a peculiar principle, to which he has given the name *echidnine* or *viperine*, which appears to be the active poisonous matter. The poison of the most deadly serpent produces no effect when introduced into the stomachs of living animals, excepting a slight irritation of the air-passages; nor is its effect more serious when applied to the surface of the skin when free from abrasion. From the experiments of Fontana "on the poison of the viper," and other observers, it seems that the venom must be introduced, directly into the subcutaneous cellular tissue. When, however, properly introduced, as through its natural channel, the poison-fang, "its effects are very rapidly manifested; in fact, in some cases so rapidly as more to resemble those of prussic acid than anything else; usually, however, a brief interval elapses before the effects are shown. These may be divided into general and local. The first symptoms in nearly all cases appear to be a general shock to the nervous system, attended with faintness, tremor, and great depression, sometimes with stupor, loss of sight, vomiting, lockjaw, and general insensibility; at the same time, great and sometimes intense local pain is set up. The limb, if the wound is in one of the extremities, rapidly swells. In severe cases, the swelling continues to spread till it reaches the trunk, or even the entire body, whose surface assumes a jaundiced hue. The gravity of the effects of the bite of a venomous snake appears to be in direct ratio to the comparative sizes of the snake and its victim, and also to the quantity of the poisonous secretion present at the time in the saccular gland. It is also greatly governed by the situation of the wound; one on an extremity, for example, being far less dangerous than one on the face or trunk. It has been remarked that two or more wounds at distant points are more rapidly effective than when they are inflicted on one spot."—Busk, *op. cit.*, pp. 926, 927. The poison is one which seems to act primarily on the nervous system, and also to have a septic action on the tissues with which it is brought in contact; and in order to produce its effects, it must be directly introduced into the circulation.

The viper is the only poisonous snake in Gt. Britain; but in other countries, there are many snakes whose bite is fatal. America possesses the rattlesnake; the East Indies, the cobra da capello, the ophiophagus, daboia Russellii, etc.; and Africa and Australia are rich in poisonous reptiles. The bite of the viper presents in a mild form the typical symptoms which have been described, and is very seldom fatal. In the case of many snake-bites, however, rapid death is the general result; and should recovery take place, it will often be very protracted and imperfect.

The symptoms produced by the bites of different kinds of venomous serpents, differ considerably in character as well as in intensity, although there is a general resemblance.

The treatment may be divided into local and general. The local treatment consists in the *immediate* application of a ligature drawn as tightly as possible above the wound—provided the situation of the latter allow of it—to prevent absorption, and the excision and cauterization of the bitten part, and then, after bathing it with warm water, sucking or capping it. When the position of the bite prevents free excision, the poisoned tissues must be destroyed by *liquor ammoniæ*, or nitric acid. The general or constitutional measures consist essentially in the very free administration of the most powerful diffusible stimulants, such as hot strong brandy or whiskey and water, and ammonia (an ammoniacal preparation, known as *eau de luce*, is a popular remedy for snake-bites). In these cases, in consequence of the prostration of the patient, he can bear an extraordinary quantity of stimulants. For the bite of the rattlesnake, the popular treatment is to make the patient drunk—a process known as the *western cure*. Olive oil, freely administered, has been strongly advocated. We append in a foot-note* a few of the so-called specific remedies said to be adopted by the inhabitants of countries where the most virulent serpents abound.

VENO'SA (anc. *Venusia*), a t. of southern Italy, in the province of Basilicata, 23 m. n. of Potenza. Its castle, which gives a picturesque effect to the quarter in which it is placed, is now in ruins. The Norman abbey of the Holy Trinity, founded by the Norman, Robert Guiscard, and consecrated in 1059, though now in ruins, is imposing from its magnitude and regularity, as well as interesting from its antiquity. But the unfailing interest of Venosa arises from its being the birthplace of Horace (see HORATIUS FLACCUS). In one of the streets is a column surmounted by the bust of the poet; and many of the localities of the vicinity can be identified with the places he has immortalized. Pop. about 8000.

* Decoction of Virginian snake-root; *radix corineæ*; guaco, or the *sacra vitæ anchora*; the Tanjore pill, whose chief ingredient is arsenic. See the article SNAKE-STONES.

VENT, or **TOUCH-HOLE**. See GUN.

VENTILATION. See WARMING AND VENTILATION.

VENTIMIG'LIA, a small fortified t. of northern Italy, in the province of Porto Maurizio, stands on a promontory on the sea-shore, 17 m. n.e.n. of Nice. Besides an old cathedral, it contains the church of St. Michel, containing two Roman milestones, and inscriptions by Augustus and Antoninus Pius. The strongly fortified castle above the town, recently repaired and strengthened, is the chief stronghold between Genoa and Nice. Wines and fruits are produced. Ventimiglia, the ancient *Albium Intemelium*, was the capital of the Intemelians, a Ligurian tribe; and its possession was contested in the middle ages by the Genoese, the counts of Provence, and the dukes of Savoy. Pop. '81, 4195.

VENTNOR, the principal t. on the s. shore of the isle of Wight, 9 m. s.s.e. of Newport. It is situated amid the finest of the fine scenery of the Undercliff. Fossils are found in great quantity in the vicinity. With a fine southern exposure, and well sheltered from the n., Ventnor possesses a mild climate, suitable for various classes of invalids, and has accordingly become a favorite winter and spring resort. The town is well provided with hotels and lodging-houses. Its beach is composed of beautiful yellow shingle. With these and other recommendations, Ventnor has risen into importance within the last 30 years. Pop. '61, 3208 · '81, 5493 ; '91, 5817.

VENTRICULITES, a genus of fossil sponges, specimens of which are of frequent occurrence in cretaceous strata. They often form the nucleus around which flints are aggregated, and give their form to the flint nodules. Indeed, it is believed by some that the flints are the metamorphosed remains of this genus, and other silicious sponges. Ventriculites are sessile, and cup-shaped, gradually opening from the base upward. Twelve species have been observed.

VENTRILOQUISM, the art of producing tones and words without any motion of the mouth, and so that the hearer is induced to refer the sound to some other place. It does not depend on any peculiar structure of the organs of the voice, but upon practice and dexterity. The name is founded upon the mistaken supposition that the voice proceeds from the belly. The art of the ventriloquist consists mainly in taking a deep inhalation of breath, and then allowing it to escape slowly; the sounds of the voice being modified and muffled by means of the muscles of the upper part of the throat and of the palate. The ventriloquist avails himself at the same time of means such as are employed by sleight-of-hand performers to mislead the attention. Ventriloquism is a very ancient art; and is mentioned by Isaiah (xxix. 4). The Greeks ascribed it to the operation of demons, and called ventriloquists *engastrimanteis* (belly-seers), and also *Euryklytes* from Eurykles, a professor of the art at Athens. In modern times a Frenchman of the name of Alexandre obtained great reputation for his mimetic representations, combined with ventriloquism and sleight-of-hand; and in England, Love was long one of the most popular ventriloquists.

VENTU'RA, a co. in s. California, having the Pacific ocean for its s. boundary; traversed by the Southern Pacific railroad; area, 1682 sq. m.; pop. '90, 10,071, chiefly of American birth. Co. seat, Ventura.

VENTU'RA DE RAULICA, GIOACCHINO, 1792–1861 ; b. Palermo ; left the society of Jesuits and joined the order of Theatines; soon distinguished himself by pulpit eloquence; became general secretary of his order; subsequently censor of the press and member of the royal council of public instruction for the kingdom of Naples; distinguished himself by his funeral orations, one of which, on Pius VII., passed through 20 editions, and gained for him the name of the Italian Bossuet; was appointed general of the order of the Theatines, 1824; resided at Rome, and elected professor of law in the Roman university; published, 1828, *De Methodo Philosophandi*, which was severely attacked by his friend the abbé Lamennais. Leaving the pontifical court, he spent 10 years studying especially the Scriptures and the Christian fathers. In 1848 he was made minister plenipotentiary to the court of Rome by the popular government of Sicily; May 4, 1849, retired to Civita Vecchia. Afterward he went to Paris, where his eloquent preaching drew immense crowds. Here he published *Les femmes de l'Evangile; La raison philosophique et la raison Catholique; Essai sur l'origine des idées; Le pouvoir Christien.*

VE'NUE is the locality assigned in pleadings in various actions at law for the acts or circumstances out of which the action arises. The rule is, that the declaration or plaintiff's pleading must set forth some venue, which is usually the county where the cause of action arose; and this shows where the trial will take place, if at all. If the other party shows that it would be more convenient and less expensive to try the action elsewhere, then he may apply to the court, or a judge, to change the venue, and thus the trial may take place in a different county from that first stated.

VE'NUS, the Roman goddess of love, subsequently identified with the Greek Aphrodite (q.v.). Originally, she does not seem to have occupied a conspicuous place in the Latin religion, and scarcely, if at all, figures in the history of Rome under the kings; a circumstance that throws no inconsiderable light on the Roman character, for it may be

taken as an indication of the grave and serious disposition of the people, who highly valued matrimony and wedded joys, but cared little for the sentimental passion of love. Gradually, however, as the myth of the Trojan origin of Rome gained ground, the worship of Venus emerged into importance. Aphrodite was the mother of Æneas, and Aphrodite became Venus; Ares was Mars, and Mars was the national god of the Roman people; and as in the Greek mythology, Aphrodite was beloved of Ares, so, of course, Venus was represented as the paramour of Mars, and thus was advanced by the poets to the dignity of the divine mother of the Roman people. Several temples were erected to her in Rome at different times and under different names, and rites were celebrated in her honor during the month of April—the spring-time of the year being thought favorable to the growth of tender emotions.

The figure of Venus was a favorite subject of ancient sculptors. One of the most famous specimens extant is the "Venus de' Medici," preserved in the Uffizi gallery at Florence, and generally admitted to be the finest relic of ancient art. It was dug up in several pieces, either at the villa of Hadrian, near Tivoli, or at the portico of Octavia, in Rome, in the 17th c.; and after remaining for some time in the Medici palace in Rome (whence its name), was carried to Florence by Cosmo III. about 1680. It is a nude statue, 4 ft. 11½ in. in height, without the plinth; and from the exquisite symmetry and grace of the figure, it has become a sort of standard of excellence for the female form. The sculptor was Cleomenes, the Athenian (200 B.C). The beautiful "Venus of Milo," now in the Louvre at Paris, is so called because it was found in the island of Milo or Melos in the Archipelago. Of modern statues that by Canova is the most famous. See illus., GRECIAN SCULPTURE, vol. VII. MYTHOLOGY, vol. X.

VENUS (see PLANETS), an inferior planet whose orbit is between that of the earth and Mercury. Her mean distance from the sun is 66,134,000 miles. The eccentricity of her orbit is only 0.00686, and her greatest distance, 66,586,000 m., only exceeds her least distance by 904,000 miles. She performs her sidereal revolution in 224.7 days, in an orbit whose plane is inclined 3° 23½′ to that of the ecliptic, but her synodical revolution requires much more time, 583.92 days. Between inferior conjunctions and the next superior conjunction Venus is the morning star, and between superior conjunctions and the next inferior conjunction, she is the evening star. Her diameter is about 7,500 m.; so that her volume is about $\frac{17}{20}$ of that of the earth, and her mass is nearly $\frac{18}{20}$ of that of the earth (more correctly $\frac{177}{200}$). The great inclination of the equator of Venus to the plane of her orbit, about 50° (by some estimated to be more), and the great amount of solar heat received—about twice as much as is received by the earth—it is believed totally unfits her for human or perhaps any but the lowest animal life. A dense, cloudy atmosphere is believed to envelop her, but observations indicate that there are lofty mountains rising from her surface to a height of 20 miles. Venus, like Mercury, crosses the face of the sun, as seen from the earth, but her transits are not as frequent. They, however, possess more importance, because, from being nearer, her position on the sun's disk varies much with different points of observation, thus allowing of a method of angular measurement of her distance.

VENUS. See VENERIDÆ.

VE'NUSBERG, the name of several mountains in Germany, especially in Swabia; it appears to be met with in Italy also. It occurs for the first time, so far as is known, in a poem called the *Children of Limburg*, composed in the Netherlands about 1337 (published by Van den Bergh, Leyden, 1846); but since then it is met with frequently in the literature of the 15th and 16th centuries, and has been preserved to the present day in legends and popular songs. According to these accounts the lady Venus holds her court in the interior of such mountains, in brilliant style, with song and dance, banquets, and all kinds of revels. Persons of earthly mold now and then visit her abode (they are always represented as *descending*), and tarry longer or shorter time, some even to the day of judgment, leading a life of perpetual delight; e.g., Heinrich von Limburg, a hero of the above-mentioned romance, and the noble Tannhäuser (q.v.). Yet they usually run the risk of eternal perdition; and, therefore, the faithful Eckhart sits before the entrance of the mountain, and warns people against entering. Nor does the condition of the sojourners always present so enticing an aspect; on the contrary, there are at times heard issuing from the mountain the lamentations of the damned; and Geiler von Keisersberg makes the witches in their night-expeditions rendezvous in the Venusberg. On putting together the various traits of these traditions it is apparent that they originated in the mythology of the highest German antiquity. The lady Venus is, under a name borrowed from the classical mythology, the universal divine mother of the old German belief, in her peculiar conception of subterranean goddess—the same being that appears under several other German names, each bringing forward some particular side of her character; e.g., Hulda (q.v.), the gracious, benign; Hilda, war; Berchta (q.v.), the shining; Hel, the concealed (from which our hell is derived). In this character of goddess of the under-world she is surounded by the elves and other subterranean spirits, unbaptized children, fallen heroes, and the wise women devoted to her services, who, in the way of thinking of later times, were degraded to witches. The queen of Elfland, or Faery, is evidently only another form of the lady Venus modified by a more decided mixture of Celtic and classic elements.—See Tale of Tamlane, and Thomas the Rhymer in *Minstrelsy of the Scottish Border.*

VENUS'S FLOWER-BASKET. See ZOOPHYTE.

VENUS'S FLY-TRAP. See DIONÆA.

VENUS'S LOOKING-GLASS, *Specularia speculum*, a very pretty little annual, of the natural order *campanulaceæ*, which has long been a favorite in flower-gardens, and it is a native of corn-fields in the s. of Europe. It has brilliant blue, white, or violet-colored flowers, which fold up in a pentagonal manner toward evening.

VERA CRUZ, a maritime state of Mexico, consisting of a belt of territory about 500 m. long by 80 broad, stretching along the s.w. of the gulf of Mexico; 26,201 sq. m.; pop. '95, 855,975, chiefly creoles and Indians. The coast region, a strip about 30 m. wide, is low, level, and sandy, its most characteristic feature being its lagoons. In the s.e. corner of the state is the isthmus of Tehuantepec (q. v.). Its climate is hot and unhealthy, yellow fever prevailing from May to November. The interior slopes upward to the volcanic mountain range of the Sierra Madre by which it is traversed, culminating in the peak of Orizaba, 17,314 ft. high. It presents all varieties of climate from tropical to arctic, and a corresponding variety of vegetable products both of torrid and temperate zones. The middle region is fertile, and covered with magnificent forests and plantations of sugar, coffee, tobacco, corn, etc., and is agreeable and healthy. Among the mineral products are gold, copper, iron, and lead.

VERA CRUZ, or VILLA NUEVA DE LA VERA CRUZ (the New City of the Real Cross), an important city on the e. coast of Mexico, about 180 m. e. of the city of Mexico, with a pop., 1895, of 88,993, composed of a motley collection from many nations. The city is built in a semicircle facing the sea, and is regularly laid out; the streets, which are wider than is usual in tropical countries, running e. and w. from the harbor, with others crossing them at right angles. The town is well defended by a strong wall and other substantial works, as also by the castle of St. Juan de Ulloa, which stands upon an island of the same name, about half a mile from the shore. The principal buildings are the cathedral, and other churches, generally built in the Moorish style, several monasteries; the court-house and prison, which stand on one side of the great square in the center of the city. There are a few good hospitals. The drainage of the city flows down open channels in the center of the streets, which are almost on a level with the sea. This, combined with the wretched water which the inhabitants are compelled to use, the marshy and utterly barren nature of the surrounding country, and the pestilential nature of the climate generally, easily accounts for the frightful ravages of yellow and other fevers. Yellow fever is most prevalent from May till November. Although it is the chief port for all Mexico, Vera Cruz has no harbor, but only an open roadstead between the town and the castle. The anchorage is exceedingly bad, and when the n. gales, or *nortes* (terrible hurricanes, bearing along with them clouds of sand from the sand-hills behind the town), prevail, many vessels are wrecked on the adjoining shore. A breakwater is in process of construction, which will do much towards improving the harbor. A railway between this city and Mexico was begun in 1864, and completed in 1869. There is also to be an interoceanic line to Acapulco.

The chief exports are the precious metals, cochineal, sugar, flour, indigo, provisions, sarsaparilla, leather, vanilla, jalap, soap, logwood, and pimento; and the imports, cotton, woolen, linen, and silk goods, brandy, iron, steel, wax, quicksilver, paper, hardware and cutlery, earthenware, etc.—OLD VERA CRUZ, a village to the n., was the first Spanish settlement on the coast.

VERAGUA, DUKES OF, the title borne by the successors of Columbus, bestowed originally upon Luis Columbus the grandson of the discoverer. The male line became extinct on the death of Diego Columbus in 1578, and the succession was settled on the descendants of Diego's sister. The Duke of Veragua (b. 1837) visited the United States on the occasion of the Columbian centennial in 1892.

VERATRIA, CEVADINE, $C_{32}H_{49}NO_9$, an alkaloid occurring in cevadilla (the dried fruit of *usagræa officinalis*), in the bulbs of *colchicum autumnale*, and in the roots and seeds of different species of *veratrum*. Cevadilla is the source from which it is most readily obtained; and for the method of extracting it we must refer to the pharmacopœia. In a state of purity, it is a pale, gray, amorphous powder, without smell; but even in the most minute quantity, powerfully irritating to the nostrils, sometimes producing dangerous fits of sneezing. It is strongly and persistently bitter, and highly acrid; insoluble in water, sparingly soluble in spirit and ether, but readily in diluted acids. Heated with access of air, it melts into a yellow liquid, and at length burns away, leaving no residue. In France it is much used as an internal remedy for pneumonia and acute rheumatism, and for the latter its efficacy is well established. It is given in the form of pills, containing $\frac{1}{14}$ of a grain, of which three may at first be given daily, and the number increased up to eight or ten, unless pain in the throat or stomach, vomiting, or diarrhea supervene, when their use must be suspended till these symptoms disappear. In this country it is chiefly employed externally in the form of "ointment of veratria" for neuralgic affections, and for scrofulous diseases of the joints. It is an extremely acrid and violent poison, and must be prescribed with great care.

VERA'TRUM. See HELLEBORE.

VERAZZA'NO, Giovanni da, 1480–1527; b. Italy; of a noble family; in the service of Francis I. of France sailed on a voyage of discovery to North America in 1524. He went by way of Madeira, in command of the frigate *Dauphin,* and after weathering a great storm reached the e. coast of North America, and sailed along it from the 34th degree of latitude to Newfoundland. He discovered the continent at cape Fear or New Jersey, and is supposed to have discovered New York bay. The genuineness of a letter to Francis I., giving an account of his discoveries, has been questioned. He is said to have been put to death in Spain for piracy.

VERB (Lat. *verbum,* a word), the name given in grammar to that part of speech (see Parts of Speech) which predicates or affirms. See Sentence. As the very end of speaking is to assert or affirm something with a view to being believed or disbelieved, the part of speech which performs this office is, as it were, the soul of the sentence, and is called "the word," or verb, par excellence. Verbs affirm either some action or some state; as, "John *reads;*" "the sun *shines;*" "the book *lies* on the table." When the nature of the action requires an object to complete the sense, the verb is called *transitive,* because the action *passes over* (Lat. *transit*) to an object; as, "the child strikes *the dog.*" Some verbs complete the conception of the action in themselves, and require no complement; as, "the child *sleeps,*" "the bird *flies.*" These are called *intransitive.* A distinction is attempted to be made between intransitive verbs expressing action (as *flies, moves*), and verbs expressing merely a state (as *sleeps, lies*), the latter being called *neuter* verbs. But it is often impossible to draw the line where activity ends and neutrality begins. Even in such a verb as *sleeps,* it is implied that the sleeper shows certain outward manifestations that make an impression, or act, on the beholder; when we affirm that an object *stands, lies,* or even only *exists,* or *is,* we in fact affirm that it "acts," in this sense. All verbs, then, agree in affirming action.

Nor can any exact or permanent division be made of verbs into transitive and intransitive. We can say whether a given verb in a particular sentence is used transitively or intransitively; but not that it is absolutely, and in itself, transitive or intransitive. It would be difficult, perhaps, to find a verb that cannot be shown to be both the one and the other. "The child *sees* the candle" is unquestionably an instance of a transitive verb; in, "the newborn child *sees,* but the puppy is blind," the same verb is unquestionably intransitive. A verb used transitively has reference to particular acts; when the action is to be *generalized,* all specification of an object is dropped, and the verb becomes intransitive. Ex., "men *build* houses" (trans.); "men *build,* and time pulls down" (intrans.).

Intransitive verbs generally express a kind of action that we think of, at least, as composed of a number of parts, all like each other; as, he *walks, runs.* Now, with regard to the particular parts, we generally find that the same verb takes an object after it; as, "he walks *a step, a mile, a long way;*" "John played *a stroke, a piece, a game;* "he did not sleep a *wink*" (sleep being a prolonged winking). That any intransitive verb can take its cognate noun as an object, is a received doctrine. Ex., "he *ran* a *race;*" "they *died* an easy *death.*"

There are two classes of transitive and intransitive verbs, related to each other, in the following way:

Intransitive.	Transitive.
he sits.	he sets (causes to sit).
" lies.	" lays (" " lie).
" falls.	" fells (" " fall).
" rises.	" raises (" " rise).
" sucks.	" soaks (" " suck).
" drinks.	" drenches (" " drink).
" dives.	" dips (" " dive).

Those in the second column are called *causative* verbs. In the ancient forms of our language there were many more such causative verbs, formed from root-verbs by a change, generally of the vowel. In Hebrew every verb is capable of assuming the causative form. Modern English does not stand much on forms, but employs almost any verb in a causative sense without change of any kind. Thus, "The horse *walked*"—"the groom *walked* the horse;" the wood *floated*"—"raftsmen *floated* the wood down the stream."

Passive Form, or Voice, of Verbs.—Instead of "Cæsar *defeated* Pompey," we may say, "Pompey *was defeated* by Cæsar." In the former, the verb is in the *active voice;* in the latter, in the *passive voice.* In using the passive voice, the thing or person acted upon is made the subject of the sentence, and has the chief attention directed thereto; with the active voice, the doer and his action are more prominent. Of course it is only transitive verbs that can thus have a passive voice.

One class of intransitive verbs become transitive by the addition of one of the class of words called prepositions; as, *speak—speak to; fall—fall upon.* Some verbs already transitive take prepositions simply to modify the sense: as, *set—set up, break—break down.* In such cases, the verb and preposition are to be considered as forming one compound verb, and might be written with a hyphen—speak-to, break-down. With the

addition of a preposition, what was an intransitive verb becomes capable of being used in the passive voice. Thus, "the king spoke to the duke about it"—"the duke was spoken to about it by the king." "Robbers fell upon him"—"he was fallen upon by robbers."

Not, however, in all cases. For, "the Hudson runs into the sea," we could not say, "the sea is run into by the Hudson." And yet, with this same verb, we can say, "the mail-train was run into by the express." The distinction seems to be that when we think of the object as sensibly affected by the action, and wish to call the chief attention to the effect so produced, the object may become the subject, and the verb be passive.

VERBENA'CEÆ, a natural order of exogenous plants, consisting chiefly of trees and shrubs, but partly also of herbaceous plants. The leaves are generally opposite and simple, and have no stipules. The flowers are generally in corymbs or spikes; the calyx is tubular, persistent, inferior; the corolla hypogynous, tubular, its limb usually irregular; the stamens generally four, two long and two short, sometimes equal, sometimes only two; the ovary 2 to 4 celled, the style solitary, terminal; the fruit composed of 2 to 4 achœnia united, sometimes fleshy; the seeds 1 to 4. The order contains almost 800 known species, chiefly tropical, some of them natives of temperate countries. The verbenaceæ are allied to *labiatæ* both in botanical characters and in properties, but the leaves have no oil-glands. Some are beautiful ornaments of flower-gardens and hot-houses; some are highly esteemed for their fragrance; some are used in medicine, as vervain (q.v.), etc., although no medicinal plant of much value belongs to the order; the fruit of some species, as *premna esculenta* and species of *lantana*, is eaten; the leaves of *stachytarpheta jamaicensis* are used as a substitute for tea; and the timber of a number of species is valuable. To this order belongs the teak (q.v.) of India.

VERBOECK'HOVEN, Eugene Joseph, b. Waerten, West Flanders, 1798; a Belgian animal-painter of repute, several of whose works are in the United States. Among these may be cited his "Herd of Sheep overtaken by a Storm," "Horses attacked by Wolves," "Herd of cattle in the Roman Campagna." He was further known by his etchings and sculptures. He d. 1881.

VERCEL'LI, a venerable city of northern Italy, in the province of Novara, stands in a fertile plain, on the right bank of the Sesia, 44 m. w.s.w. of Milan by railway. It covers a wide area, is surrounded by boulevards—those on the n.w. side commanding a magnificent view of the Alps—is the seat of a bishop, and has the appearance of great prosperity. The cathedral, an edifice of about the middle of the 16th c., has a library containing a collection of ancient and valuable MSS. Vercelli is a thriving commercial city. Pop. '81, 20,165.

VERCHÈRES, a co. in s.w. Quebec, having the St. Lawrence river on the w. and n., and on the e. the river Richelieu; 195 sq. m.; pop. '91, 12,257. Co. seat, Verchères.

VERDE-ANTIQUE, a beautiful stone of a dark-green color, with patches of white, and sometimes also black and red. It is a kind of hard breccia, and was much prized by the ancient Romans, and is still in great favor in Italy.

VERDEN, a t. of Prussia, once capital of a duchy, in Hanover, on the right bank of the Aller, 3 m. from the confluence with the Weser, and on the railway to Hanover, from which it is distant n.n.w. 54 miles. Pop. '90, 8719.

VERDI, Giuseppe, composer, b. in Le Roncole, near Busseto, Parma, Oct. 9, 1813. His parents kept a small inn at Le Roncole and a little provision shop. At an early age he showed musical talent, and his father gave him a spinet and had him taught music. He was organist in his native town at the age of ten, and was aided by a prosperous grocer Barezzi, a friend of his father, who was a leader of music in Busseto. He made up a purse and sent him to Milan, but Verdi was refused admission at the Conservatorio on the ground that he had little talent. He took private lessons with Lavigna of the La Scala. In 1833 he was called to Busseto to become organist and maestro di cappella at the cathedral and conductor of the Società Filharmonica. The cathedral refused to give him the post, which enraged the Filharmonica to such an extent the orchestra refused to play for the church. This led to riots and the temporary suppression of the society. In 1836 Verdi married Marghenta Barezzi, the daughter of his benefactor, and in 1838 they went to Milan to try to have an opera represented. In 1839 *Oberto* was brought out at La Scala with success, and in 1842 his *Nabucco* gave him reputation. A list of fiascos followed until *Rigoletto* ushered in his day of fame. Verdi's style is careless, but he possesses the true gift of melody. His instrumentation is thin, and his harmony poor. It is probably his passionate warmth and dramatic power that have rendered him so popular. His *Trovatore* and *Traviata* are known all over the world, but his best work is *Aïda*, written for the Khédive of Egypt and represented in Cairo in 1871. In this opera he changed his old simple style for one more studied and more artistic. He wrote twenty-eight operas, the best known of which are: *Nabucco*, Milan, 1842; *I Lombardi, alla prima crociata*, 1843, revised as *Jerúsalem*, Paris, 1847; *Ernani*, Venice, 1844; *I due Foscari*, Rome, 1844; *Giovanna d'Arco*, Milan, 1845; *Macbeth*, Florence, 1847; *I Masnadieri*, London, 1847; *Luisa Miller*, Naples, 1849; *Il Trovatore*, Rome, 1853; *La Traviata*, Venice, 1853; *Des Vêpres Siciliennes*, Paris, 1855; *Simone Boccanegra*, Venice, 1857; *Un ballo in maschera*, Rome, 1859; *Don*

Carlos, Paris, 1867; *Aïda*, Cairo, 1871; *Otello*, Milan, 1887, and *Falstaff*, Milan, 1893. His other works are cantatas and church music, including the celebrated *Manzoni Requiem*, performed in the church of San Marco, Milan, on the anniversary of Alessandro Manzoni's death, May 22, 1874; pianoforte and chamber music; and romanze for voice with pianoforte. On the production of *Falstaff*, the king of Italy created Verdi marchese of Busseto. In 1896 Verdi gave 1,000,000 lire ($200,000) to found a home for musical artists in Milan. See Pougin, *Verdi, souvenirs anecdotiques* (English translation by James E. Matthews, London, 1887); and Blanche Roosevelt, *Verdi*, Milan, and *Otello*, (London, 1887).

VERDICT, in law, is the finding of a jury as to the issue of fact raised between the parties. The usual verdict in criminal cases is guilty or not guilty; in civil cases, it is a verdict for the plaintiff or for the defendant, according to the fact. These are called general verdicts. In some civil cases, the jury, when doubtful, or when the court directing them is doubtful how the law ought to be applied to the facts, find a special verdict, i.e., specific facts, leaving the court to draw the proper conclusion. A verdict by a jury is usually conclusive in all criminal cases, and no new trial can be had; but in civil cases, the party defeated may, within a certain number of days allowed by the practice of the court, move to set the verdict aside, and apply for a new trial on various grounds; as, for example, that the judge misdirected or misled the jury; that the verdict was against the weight of evidence, or was perverse, etc. See Not Proven.

VERDIGRIS is the popular name for basic copper acetate, $(C_2H_3O_2)_2Cu_2O+6H_2O$, a substance which is largely used for commercial purposes, and as an external application in surgery. It is prepared on a large scale by piling up copper-plates with alternate layers of marc or fermenting grape-skins. In the course of a few weeks, the surface of the copper is covered with a crust of the salt, which is detached, made into a thick paste with vinegar, and pressed into molds. The salt thus obtained is in the form of a bluish-green tough mass, which is not easily pulverized. The formation of the salt by this process is due to the alcohol in the grape-skins being slowly oxidized into acetic acid, while the copper absorbs oxygen from the air, and the oxide thus formed unites with the acetic acid. Verdigris may be obtained more directly by placing the copper sheets in cloths dipped in vinegar. Verdigris is permanent in the air; when heated, it first loses water, and then acetic acid, the residue being metallic copper. Water resolves it into an insoluble tribasic acetate, and a soluble subsesquiacetate of copper—a point which must be recollected in employing this salt. It is used by the surgeon as a caustic application to venereal warts and fungous growths ; it is also a good application in ophthalmia tarsi, and has been of much service in stimulating old and indolent ulcers, in the ulcerated sore throat of scarlatina, and in malignant ulcer of the tongue. It may be used in the form of an ointment or a liniment. The latter, formerly known as *mel Ægyptiacum*, is composed of 1 ounce of powdered verdigris, 7 ounces of vinegar, and 14 of honey. The verdigris is dissolved in the vinegar, and to the strained solution the honey is added, and the whole is boiled to a proper consistence. It should be applied with a camel-hair pencil.

Verdigris is an active irritant poison, but is much more commonly the source of accidental than intentional poisoning, it being often formed in copper vessels used for cooking, or in the very reprehensible practice of putting copper coins into pickles to give them a fine green color. If copper vessels for cooking are kept perfectly clean, they seem not to be dangerous, provided (1) no acid matter be placed in them; (2) that the boiled materials are at once poured out, and not allowed to stand to cool in them ; and (3) that the vessels are always at once cleaned. But the interior of such vessels should always be tinned, care being frequently taken that the tinning remains entire. In cases of poisoning the best treatment consists in the free administration of white of eggs and milk.

VERDITER, a pigment which is extensively used in common painting. It is either blue or green, the latter being generally known as Bremen green. It is formed by a very complicated process from blue vitriol, or sulphate of copper, sea-salt metallic copper, muriatic acid, caustic potash, and water, and occupies three months in its manufacture. The blue is most valued.

VERDOY, in heraldry, a term indicating that a bordure is charged with flowers, leaves, or vegetable charges. Thus, a bordure argent verdoy of oak-leaves proper is equivalent to a bordure argent, charged with eight oak-leaves proper.

VERDUN, (anct. *Verodunum*), a fortified t. of France, in the dep. of Meuse, stands on the right bank of the Meuse, 174 miles (direct line) e.n.e. of Paris. It was fortified by Vauban, and its defenses consist of a wall with bastions and a citadel. It is the seat of a bishop, has a fine cathedral, and carries on various manufactures. In Nov., 1870, it was taken by the Germans, who thus established better communication between Germany and the troops before Paris. Pop. '91, 18,852.

VERE, Sir Aubrey **HUNT** de, 1788–1846, an Irish baronet, author of two dramatic poems *Julian the Apostate* and the *Duke of Mercia*, as also of *A Song of Faith, and other Poems.*

VERE, Aubrey Thomas de. See De Vere.

VERE, DE, a noble family of England, of which the most distinguished members were: JOHN, 1450–1513, 13th earl of Oxford, who fought as a Lancastrian in the "wars of the Roses," had a command under Henry VII. at Bosworth, and as lord high steward pronounced sentence on the earl of Warwick: EDWARD, 17th earl of Oxford, 1540–1604, an Elizabethan poet and wit of fashion; sat on the trials of the earls of Essex, Arundel, and Southampton, and that of Mary, queen of Scots, as lord high chamberlain; and held a command in the fleet sent out in 1588 against the Spanish Armada: AUBREY, 20th earl, who fought as a royalist in the rebellion, was lord lieut. of Essex under Charles II., and was dismissed by James II. in 1687 for refusing to aid that monarch in his schemes.

VERESTCHAGIN, VASILI, was born in the province of Novgorod, in 1842, of a well-to-do family of land owners. He wished to be an artist; his father wished him to be an officer of marines. He became both, passing his work-hours at the naval school and his play-hours at a school of design. He left the naval school as first scholar, and eventually won a silver medal at the Academy of Fine Arts. He remained in the navy but a short time, leaving it at twenty to devote himself to Art. He first traveled to Paris and the Pyrenees and finally to the Caucasus, pen and pencil in hand. In 1864 he set out for Paris with his sketches to be worked up. He had had considerable indiscriminate practice in rendering what he saw, and he exhibited the most downright sincerity in his way of looking at it. He went to the great Gérôme and told him he wished to study with him or with nobody, and was admitted to his studio. He was an industrious worker, but liked to work in his own way, playing truant from the antique to nature, and from marble to flesh and blood. His instinct was to wander away from the beaten track in search of subjects, passing his vacations in the far east of Europe, or even in Persia, among those ragged races not yet known to Art. In 1867 Gen. Kauffman, who was going into Central Asia to punish the Turkomans, invited Verestchagin to join him as an Art volunteer. It pleased him, and he started, entering Samarcand with the victorious host. Both sides fought like demons, and the artist sketched. He was in a new realm of the picturesque in nature, and he found abounding wealth in character there. Dervishes, politicians, falcon hunters, soldiers in all their brutality, dirt, ignorance, and laziness. Verestchagin's principal characteristic is his individuality. He seems to be impressed, at once, with the strongest points of his subject, and in the human face seizes the innermost meaning, which he places upon the canvas with intense reverence. As a colorist he is inclined to strong contrasts, and here he shows somewhat the influence of Munich, where he has painted a great deal. In 1873 he started for British India, where he found an extraordinary field, which has been left long unexplored by artists. Color, costume, architecture, variety of type are here, and yet for centuries men have found nothing newer to paint than Italy and Spain. His Indian pictures are remarkable, but scarcely equal to those of Central Asia. The most comprehensive of these is "The Future Emperor of India," representing the Prince of Wales entering Jeypore on a richly caparisoned elephant, followed by a long procession of lesser magnates. "The Chief Mosque in Futtehpore Sikri," with worshipers, exhibits much sentiment and an astonishing mastery of *technique*. On his return from India he turned his attention to the Russo-Turkish war. He followed the armies and saw it all, a civilian in name, but a soldier still. He shipped on board one of the torpedo boats and stole up to a Turkish craft, but was wounded and lay between life and death for weeks. He recovered in time to see and paint Shipka and the final rush on Constantinople. There is a world-wide difference between his war pictures and those of the earlier Frenchmen, with their pretty uniforms and prancing steeds; truth in all its bloody aspects stares at us from his canvases and deeply impresses the horrors of war. In the fall of 1888 Verestchagin visited the United States and exhibited 131 of his best works, besides sketches and many curiosities of Russia and India. At certain hours he received in a quaintly decorated apartment, amid his glowing canvases, those of his admirers who desired to see him. Perhaps the three most impressive of his pictures represent the different methods of capital punishment: in ancient Rome, "Crucifixion;" in British India, "Blowing from Guns;" and in Russia, "Hanging." One of the most spirited war pictures is "Skobeleff at Shipka." It is the day after the battle, when Skobeleff reviews his troops while yet the dead lie in heaps around, and putting spurs to his horse gallops down the line, waving his cap and thanking his soldiers for the victory. Among others are, "The Emperor Alexander II. before Plevna," "The Conquered," in their graves, and "All Quiet at Shipka." Some of his sacred subjects are particularly touching—"Solomon's Wall," "Christ on the Sea of Tiberius," "Jesus in the Desert," and "The Prophecy."

VERGA, GIOVANNI, a distinguished Italian novelist and dramatic writer, born at Catania, Sicily, in 1840. His earliest effort, *Una Peccatrice*, passed unnoticed, but *Eva* and *Storia di Una Capinera*, which followed, psychological studies of deep insight, established his reputation. *Tigre Reale*, *Il Marito di Elena*, and *Eros* followed at short intervals; but it was not until the publication of *Nedda* and *Vita dei Campi*,—a series of masterful sketches, dealing with the passions and privations of the Sicilian peasantry,—that he struck his true vein. Two of these sketches he has since dramatized, *La Lupa* and *Cavalleria Rusticana*, the latter rendered doubly famous by the acting of Eleanora

Duse, and the music of Mascagni. Verga's latest and strongest novels are *I Malavoglia* and *Maestro Don Gesualdo*, forming the opening volumes of a series of Sicilian Stories, under the general title of *I Vinti* (*the Vanquished*). With his fellow-townsman Capuana, Verga stands at the head of the Italian "verists," and his manner has frequently been compared to that of Zola.

VERGENNES', a city in Addison co., Vt.; on Otter creek and the Central Vermont railroad; 7 miles from lake Champlain, 21 miles s. of Burlington. It contains the Vermont state reform school, graded and parochial schools, public library, electric light plant, several hotels, national banks, and manufactories of curtain and shade rollers, nails, road machines, furniture, sashes, doors, and blinds, and granite work. It affords fine views of the Adirondack and Green mountains, has steamboat communication with the lake ports, and was the building and fitting-out place of the fleet with which Capt. MacDonough captured the British squadron off Plattsburg in 1814. The creek at this point is 500 feet wide and has a fall of over 30 feet, furnishing excellent power for manufacturing. Pop. '90, 1773.

VERGENNES', Charles Gravier, Comte de, 1719–87; b. France; minister to the electorate of Treves in 1750. He was ambassador to Turkey, 1754–68; afterwards to Sweden. He was made minister of foreign affairs by Louis XVI. in 1774, after taking an active part in bringing about the revolution in Sweden. During his administration were signed the treaty with the United States in 1778, and with England, closing the revolutionary war, in 1783.

VERGIL, Polydore, abt. 1470–abt. 1555; b. Urbino; a prolific author, his best known work being *Historia Anglica*, a history of England from the earliest times to the end of the reign of Henry VII. Sent to England as collector of Peter's pence (of which office he was the last holder), he remained in that country during the most of the remainder of his life, receiving successively the rectorship of Church-Langton, the archdeaconry of Wells, and prebends in the cathedrals of Hereford, Lincoln, and St. Paul's, London. After a residence of nearly 50 years in England he returned to end his days in his native land with permission to hold his archdeaconry, as also his Hereford prebend. His Latin style is admired for its neatness and lucidity.

VERGNIAUD, Pierre Victurnien, 1759–93; b. Limoges, France. He was the most eloquent member of the *Gironde*, and in 1791 was elected to the legislative assembly and became a leader of the *Gironde*. In the national convention he was raised to the presidency, in which capacity it fell to him to pronounce sentence on the king. He was a keen opponent of Robespierre and the Montagnards, and in 1793 was, with the other prominent members of his party, brought before the revolutionary tribunal, and sentenced to death Oct. 30, which sentence was executed next day.

VERIFICATION, in law, a legal term used in pleading by a party setting forth that he stands ready to establish the truth of those facts to which he has pleaded, if they be such as amount to "new matter," the form being "and this he stands ready to verify." The practice of equity and of the civil codes of some states requires a plea to be verified by appended affidavit.

VERJUICE, a vinegar formerly much used, made from sour cider, or from the juice of the wild crab. The expressed juice of unripe grapes is another kind of verjuice used in the vine districts. Both are occasionally employed in cooking.

VERLAINE, Paul. See Symbolism.

VERME'JO, or *Bermejo*, an important affluent of the Paraguay (q.v.).

VERMES (Lat. worms), the name given by Linnæus to one of the classes in his zoological system, in which he included all the lower invertebrate animals, whether of worm-like form or not. The study of their structure has since led to their arrangement in several distinct classes, and the Linnæan term is altogether disused.

VERMICULATION, checkering or chanceling formed in mason-work as an ornament, giving the appearance of being eaten by worms.

VERMIFORM APPENDIX, a long, narrow, worm-shaped portion of gut about the diameter of a good-sized goose quill, or larger, and varying in length from three to six inches. It springs from the posterior and inner aspect of the first portion of the large intestine, near its lower end.

It is the rudiment of a lengthened cæcum found in all mammals excepting some of the higher apes and the wombat, in which the appendix exists. A brief review of the main facts concerning the development of the first portion of the large intestine, seems essential to a fair understanding of the anatomy of the vermiform appendix.

In the fœtus we find the cæcum, or blind extremity of the first portion of large intestine, represented by an elongated, fusiform diverticulum. At birth this has become a long, coiled, conical tube, tapering to a point. Very early this begins to dilate throughout its greater portion, and to become expanded into pouches or *haustra*, which give to the large intestine its characteristic sacculated shape. The original fusiform fundus of the tube, however, does not dilate, but remains small, contracted, and rudimentary; and, in the fully developed condition of the alimentary canal, appears as a mere appendix to the bulging sacculated portion above, to which alone is given the name cæcum.

The appendix vermiformis, therefore, is the terminal portion of the primitive cæcum, which never dilates.

In structure it resembles closely that of the large gut. It is hollow to its tip, and its cavity communicates with that of the large bowel. Its walls are composed of muscular, elastic, and areolar tissue, and its mucous lining is similar to and continuous with the mucous membrane lining the cæcum. It is entirely covered by peritoneum, being frequently attached by a fold of this membrane to the back of the large intestine. Its functions are probably unimportant.

Situated in the right side of the abdominal cavity, in the part described as the right iliac region, it hangs suspended, as it were, from the large gut and after describing a few slight turns terminates in a blunt end. It normally projects in a direction upward and inward, and is discovered by lifting up the extremity of the large bowel. It is subject to many variations, however, as to length and position, and its anatomical relations are of the greatest importance. Sometimes it is greatly elongated and projects far out into the peritoneal cavity ; sometimes it is found bound down by adhesions to comparatively distant points, and sometimes it hangs down into the cavity of the true pelvis in close relation to the bladder and other pelvic viscera.

The appendix is not uncommonly the seat of inflammation, perforation, and abscess caused by the lodgment of foreign bodies or hard fecal concretions (see PERITYPHLITIS). Such inflammations are responsible for a large number of cases of peritonitis in youth and adult life. The appendix is approached surgically through the anterior wall of the abdomen, and has been removed successfully in a number of cases of abscess and in recurrent attacks of Appendicitis.

VERMIFUGES, VERMICIDES, or ANTHELMINTICS, are remedies which possess the property of destroying intestinal worms, or of expelling them from the digestive canal. The only worms whose presence in the intestinal canal is so common, that the remedies for their destruction and expulsion require special notice, are the two varieties of tapeworm known as *tænia solium* and *tænia mediocanellata*, or the *hooked* and the *hookless tapeworm* (q.v.), the *ascaris lumbricoides* or *large round worm*, and the *ascaris* or *oxyuris vermicularis*, or *small threadworm*. A few of this class of medicines are said to be useful in destroying all these kinds of worms—viz., the tapeworms, the round worms, and the threadworms. In this category, we may place *absinthium*, or *wormwood*, whose effects are doubtful; *sabadilla*, or *cevadilla; santonica*, or *worm-seed*, and its active principle, *santonine* (q.v.); and *oil of turpentine*. As in our notices of the different human entozoa, we have referred to this article for the appropriate treatment of each, we will commence, in consequence of its greater importance, with the remedies that have been recommended in tapeworm, ranging them according to the repute in which they stand. (1) The root of the male-shield-fern (*aspidium filix mas*), of which the best preparation is the "liquid extract of fern-root" of the *Pharm. Br.* It may be taken in the morning before breakfast, in doses of about a scruple, in the form of an emulsion with yelk of egg, syrup of orange-peel, and water; and if the worm does not come away in six hours, a brisk purgative should be administered. Generally, however, it is expelled by a single dose, in the mass, and without pain or much uneasiness. (2) *Cusso* or *kousso*, the flowers of *brayera anthelmintica*, in doses of from half-an-ounce to an ounce of the flowers (infused for a quarter of an hour in ten ounces of lukewarm water and a little lemon-juice), or of four ounces of the infusion of the *Pharm. Br.*, and following in four hours, if it has not acted, by a dose of castor oil, is a safe and very sure remedy. (3) Decoction of the bark of the root of the pomegranate tree (*granati radix*). (4) Oil of turpentine (q.v.) ; and besides these, which are the best remedies, the seeds of the common pumpkin (*cucurbita pepo); kamela*, the powder adhering to the capsules of *rottlera tinctoria;* santonine, etc., have found their advocates. All these medicines should be taken fasting, or after a light supper on the previous evening.

Foremost among the remedies for *ascaris lumbricoides*, Dr. Cobbold places *santonine* (q.v.); but kamela is also very efficacious in doses of from one to two drams every four hours. Dr. Waring in his *Materia Medica* gives a long list of remedies employed with success in the east, but unknown in this country. *Ascaris vermicularis*, or the *threadworm*, is more successfully attacked locally in the rectum by injection, than by medicines administered in the ordinary method. Among the best forms of enemata are half a dram of tincture of sesquichloride of iron in a little gruel, retained in the bowel as long as possible, or injections of salt and water, or of infusion of quassia. As an internal remedy, santonine is the best. The most annoying symptom occasioned by these worms, the intense itching about the lower part of the bowel, especially in the evening and at night, is best relieved by the introduction of a little mercurial ointment within the verge of the anus when the patient retires to rest. See WORMS.

VERMIGLI, PIETRO MARTIRE (PETER MARTYR), 1500–62; b. Florence; an Italian ecclesiastic of the order of St. Augustine, whom intercourse with Valdes, a Spanish convert, and study of the works of Zwingli, Melanchthon, etc., induced to adopt the views of the reformers. Having avowed his conversion at Lucca, he was necessitated to flee thence to Switzerland, whence he passed to Strasbourg, in whose university he received the chair of divinity. Invited by Cranmer to England he was, in 1547, appointed by Edward VI. lecturer on the Scriptures at Oxford. Driven from England by the Marian

UNIVERSITY OF ILLINOIS

persecution he resumed his chair of divinity at Strasburg, assuming also that of Aristotelian philosophy, both which he held till 1556, when he became professor of theology at Zürich. In 1561 he attended the celebrated conference of Protestant divines at Poissy, France, and died next year, much regretted, at Zurich. He was one of the most learned and most tolerant of the reformed communion. His works were published in English in 1583 under the title of the *Commonplaces of the most Famous and Renowned Divine, Doctor Peter Martyr*, dedicated to Queen Elizabeth.

VERMILION, or artificial cinnabar (q.v.), is a bisulphide of mercury, formed by mixing 100 parts of the metal with 16 parts of sulphur, and subliming them in properly constructed retorts ; the result is a heavy dull red cake, an inch or so in thickness, of acicular crystalline texture, and exactly resembling in these respects the native cinnabar. When, however, it is finely powdered, it acquires the beautiful bright red color so well known in this pigment. The finest European vermilion was, until lately, made at Utrecht in Holland, and this manufactory supplied nearly all Europe. It is now, however, manufactured in other places, particularly in Istria. A new process, invented by Kirchoff, has also been introduced, and is employed in most manufactories for making the finest quality. It is called the humid process, from the employment of water, with which the ingredients are triturated at a temperature of not more than 130° Fahr., until the mixture, which is first black, turns a brownish-red, when the temperature is lowered to 114° Fahr., and steadily maintained at that until the brightest color is obtained ; it is then allowed to subside, the liquid is decanted off, and the residue washed in clean water. The Chinese have always been famous for the extreme beauty of their vermilion.

VERMILION, a co. in e. Illinois, having the state line of Indiana for its e. boundary ; 926 sq.m. ; pop. '90, 49,905. Co. seat, Danville.

VERMILION, a co. in w. Indiana, having the Wabash river for its e. boundary ; 270 sq.m. ; pop. '90, 13,154. Co. seat, Newport.

VERMILION, a parish in s. Louisiana, having the Gulf of Mexico on the s. and Vermilion bay on the s.e., watered by the Vermilion river ; 1230 sq.m. ; pop. '90, 14,234. Parish seat, Abbeville.

VERMILYE, Thomas Edward, d.d., ll.d., b. New York, 1803 ; studied at Yale College and Princeton theological Seminary, but without graduating ; ordained by the presbytery of New York ; pastor of the Presbyterian church, Vandewater Street, New York ; of the Congregational Church, West Springfield, Mass., 1829-34 ; of a Reformed Church, Albany, N. Y., 1834–39 ; became pastor of the Collegiate Reformed Church, New York. He published an *Address* before the St. Nicholas Society of New York ; a *Discourse* on the Rev. Dr. De Witt before the New York historical society ; a bicentennial discourse in commemoration of the founding of the West Springfield church, March 25, 1874. He died March 17, 1893.

VERMIN (Lat., *vermis*, a worm), a term commonly applied to small noxious animals, particularly to those which, unless their increase is checked, are apt to become excessively numerous. Of some of the applications of this term, as to parasitic insects, it is unnecessary to say anything ; but it seems proper to notice the use made of it by farmers and gardeners, with reference to quadrupeds and birds injurious to their crops, and by gamekeepers with reference to those which are destructive to game. In the estimation of the gamekeeper all those animals are vermin which are known ever to prey upon any kind of game, or to rob the nests of game-birds. He therefore wages unceasing war against foxes, skunks, weasels, woodchucks, hawks, squirrels, ravens, crows, blackbirds, and even owls. The results are not agreeable to the farmer, as, the balance of nature being thus interfered with, animals destructive to his crops multiply without restraint, particularly rats, mice, and moles.

VERMONT (Fr., *Verd Mont*, green mountain), a New England state, and the first admitted under the federal constitution ; in lat. 42° 44′ to 45° n. ; long. 71° 30′ to 73° 26′ w. ; bounded on the n. by Quebec ; on the e. by New Hampshire, the Connecticut river separating ; on the s. by Massachusetts ; on the w. by New York, from which it is separated for 105 m. by lake Champlain ; length from n. to s., about 158 m. ; breadth from 35 to 90 m. ; land area, 9135 sq.m. ; gross area, 9565 sq.m., or 6,121,600 acres.

History.—V. was originally the hunting ground of the St. Francis, Iroquois, and other Indian tribes. In 1609 Champlain visited the country, and between 1665 and 1691 the French erected forts on Lake Champlain. In 1724 emigrants from Massachusetts built fort Dummer near the site of Brattleboro. New Hampshire laid claim to all the territory, which became known as the "New Hampshire grants," 138 township charters being granted by that colony between 1760 and 1768. New York made a similar claim, and obtaining from the king a grant of jurisdiction to the Connecticut river, attempted to eject the settlers from their farms. Under the lead of Ethan Allen (q.v.) bodies of militia were formed, known as the "Green Mountain Boys," which made effectual resistance, and entering actively into the revolutionary struggle, accomplished the capture of Fort Ticonderoga, May 10, 1775. In Sept., 1775, the towns declared the grants an independent district, voting to conform to the resolutions of the Continental Congress, and in 1776 "New Connecticut, alias Vermont," applied for admission to the confederation, but was debarred by the opposition of New York. In 1777, Jan. 15, the grants declared them-

selves to be a free and independent jurisdiction or state, and again unsuccessfully applied for admission. In June, 1777, a regiment under Seth Warner was routed at Hubbardston, but on Aug. 15 an army under Gen. Baum, detached by Burgoyne from the main army for the purpose of capturing Bennington, was defeated by Green Mountain Boys, under Gen. Stark and Col. Warner. In 1778 the first legislature of the independent commonwealth assembled. Throughout the war V. provided for her own men, and at its close redeemed her paper money at par. The V. militia under the Allens and Warner distinguished themselves in the invasion of Canada, in the retreat from Quebec, and in the battles on Lake Champlain, and the refusal of Congress to admit the claims of the spirited little state, led Ira Allen and others to listen to overtures from Great Britain ; but the legislature did not favor a return to British allegiance and nothing came of the negotiations. In 1781 Congress offered to admit V., with a smaller area than at present, but she refused, and did not enter the union until Mar. 4, 1791. In 1808 Montpelier became the permanent capital. In the war of 1812 the governor refused to call out the militia, but volunteers distinguished themselves in the battle of Plattsburg and in the naval battle on Lake Champlain. During the civil war the state furnished 33,288 troops to the union army.

Topography, Geology, etc.—The main range of the Green Mts., traversing the state in a northerly and southerly direction, forms an unbroken watershed except in the n., where the Winooski, Lamoille, and other streams flowing into Lake Champlain intersect it by their valleys. The chief summits of this range are Mt. Mansfield, 4430 ft. in its highest part, Camel's Hump, 4088 ft., and Killington Peak, 4380 ft. From the central part of the Green Mts. a branch, called the "Height of Land," trends to the n.e., and passes into Canada. The Taconic range, running nearly parallel to the Green Mts. for a considerable distance on the w., rises at Mt. Equinox to 3872 ft. Ascutney, an isolated Mt. near the Connecticut River, is 3320 ft. high. The principal affluents of the Connecticut are the Passumpsic, Wells, White, Black, West, and Deerfield rivers. The streams tributary to Lake Champlain are longer, are navigable for a few m., and some pass through deep gorges and have picturesque falls and cataracts along their courses. Among the western streams are Otter Creek, and the Battenkill and Hoosac, which flow into the Hudson. Of the total area of Lake Champlain, 500 sq.m., about $\frac{1}{8}$ lies in V. The shore line is broken by rocky headlands into deep, beautiful bays, notably those of St. Albans, Colchester, and Burlington. The northern end of the lake contains some large islands. The southern end of Lake Memphremagog lies within the state, and among smaller bodies of water are Lakes Willoughby, Dunmore, and Bombazine. Mineral springs, chiefly sulphurous, are numerous. The geological formations are chiefly azoic and silurian. The Green Mts. are composed of gneiss, with interposed talcose schist. East of that range is a bed of Devonian limestone, 20 to 30 m. long ; on the w. a great belt of quartz is covered by a bed of crystalline limestone 2000 ft. thick. Along the lake are lower silurian and primordial rocks. Laurentian rocks cover a limited area in the s.w., and granite is chiefly found in the n.e. Old sea beaches, lake and river terraces, terminal moraines, etc., make the study of geology peculiarly interesting. The whole state is covered with drift. The limestones abound in fossil shells, and skeletons of the beluga, mastodon, and mammoth have been found. The state is widely famed for its marbles, especially the white granular of Bennington and Rutland cos. Translucent white, red, green-banded, dove-colored, nearly black, verd antique, and other varieties are quarried. Purple, green, and black slates, kaoline, limestone, flagging stone, novaculite, suitable for hones and whetstones, mortar sand, arenaceous quartz sand, siliceous white sand, soapstone, roofing slate, marl, manganese, paper clay, and brick clay are abundant. A carbonaceous matter resembling coal is found at Brandon. Iron ores, especially limonite, are found in many places ; galena, silver, and zinc occur in small deposits, and gold is sometimes found in quartz veins. There are copper mines in the middle and e. parts of the state. Other mineral products are asbestos, amethysts, cyanite, feldspar, mica, chalcedony, jasper, garnets, tourmaline, and sulphur.

Fauna and Flora.—The deer, panther, wolf, wild-cat, and black bear are occasionally seen in remote districts. The red fox, red squirrel, gray squirrel, chipmunk, skunk, woodchuck, mink, porcupine, raccoon, and rabbit are common. The list of birds and wild-fowl includes 8 species of owl, 6 of thrush, 4 of swallow, 7 of fly-catcher, and 8 of starling ; the bald eagle, black hawk, loon, blue heron, plover, hooded merganser, Canada grouse, shore lark, orchard and Baltimore orioles, tanager, waxwing, rose-breasted grosbeak, bobolink, fox-sparrow, ruby-throated humming-bird, bank-swallow, logcock, red-headed and golden-winged woodpeckers. Many Canadian species visit or live in the state. In the mt. streams are found abundance of brook trout ; in the ponds, pickerel, sunfish, suckers, etc. ; and in Lake Champlain, the sturgeon, muskalonge, pickerel, pike, roach, perch, whitefish, bass, salmon-trout, and other species. Among reptiles are the rattlesnake, black snake, and several species of adder. The flora comprises nearly all the plants found in New England and in addition about 30 species not met with in other states. Out of nearly 1400 species, 1200 are flowering plants, including 100 trees and shrubs. The Green Mts. derive their name from the coniferous trees, especially spruce and pine, which cover them to the summits. The coniferæ number 16 species, 6 of which are pines and 4 spruces. The larch, white cedar, red cedar, cypress, juniper, and yew are abundant. There are 9 species of oak, 5 of maple, 2 of plum, 3 of cherry, 6 of birch, 3 of ash, 3 of elm, 3 of walnut, 15 of willow, and 5 of poplar. Other

trees are the linden, tulip, hornbeam, sassafras, and butternut. The violets number 12 species, the asters 22, the golden-rods 20, the orchids 43, the ferns 43, the sedges 88, and the grasses 91.

Climate, Soil, and Agriculture.—The climate is very healthful, although the winters are long, the snows deep, and the temperature in the inland valleys sometimes falls to 30° below zero. The mean annual temperature at Burlington is 45° F.; at Montpelier, 42.76°; av. annual rainfall is 33 ins. The soil in general is a rich loam, and is very fertile in the Connecticut valley, on the western slope of the Green mts., and along lake Champlain. The hills are well adapted for pasturage, and sheep, cattle, and horses are extensively bred for market. The sheep are of the fine-wooled merino breed, and have been extensively exported to Texas, California, Colorado, and to Australia and South America for crossing with the coarser-wooled breeds. The horses of Vermont were among the first to win fame on the race-courses of the country, and include the Morgan, Messenger, and Black Hawk stock. The agricultural products have a high rank, and the percentage of improved land in the state is exceeded only by New York and Illinois. The principal crops, according to annual value, are hay, oats, potatoes, and corn. The dairy products are also extensive, with an annual production of twenty-five million tons. The State Board of Trade was established in 1888, and one of its most important duties is to look after the interests of the farmer. Fully one-third of the maple sugar of America comes from Vermont, the annual yield exceeding $1,000,000. Hops are raised in limited quantity, and along the lake shore are fine orchards and vineyards.

Industries.—In manufactures, Vermont is far behind the other New England states, but a few of her manufactures are world-renowned. The U. S. census of 1890 reported for Vermont, 3031 manufacturing establishments, employing $32,763,291 capital and 24,894 persons, paying $10,096,549 for wages, and $20,433,174 for materials, and having a combined output valued at $38,340,066. The principal manufactures are lumber from logs and bolts, planing mill products, marble and stone work, flour and grist mill products, woolen goods, paper foundry and machine shop products, hosiery and knit goods, musical instruments, patent medicines, cotton goods, agricultural implements, leather, and boots and shoes. At St. Johnsbury are made the Fairbanks scales. The first patent was taken out in 1831, and now more than five hundred varieties are made, ranging from the most delicate balances to the immense railway scales weighing 150 tons at once. The famous Estey organ works, established in 1846, are located at Brattleboro. Burlington is one of the largest lumber markets in America. St. Albans is a great market for dairy products. The first quarry in the state was opened in 1785, and now Vermont produces three-fourths the marble quarried in the United States. The first quarry in Rutland marble was opened in 1844, and now West Rutland is the chief center of the marble industry. Proctor is noted for the largest marble quarry in the world, large quantities being taken from this quarry for building purposes in numerous cities all over the country. The marble of this section is also said to be whiter and more durable than Carrara marble, which it is rapidly replacing for monumental purposes. Cavendish has quarries of fine serpentine marble; Plymouth, verde antique, equal in beauty to the Italian; Fairhaven and Castleton, slate for mantels, billiard beds, and slate pencils; Poultney and Northfield, roofing slate; and Barre, granite, remarkable for its color and texture. At Brandon are found mines of kaolin, from which fine grades of mineral paint are made.

Commerce.—Considerable foreign commerce is carried on with Canada through Burlington, which is the port of entry of the U. S. customs districts for the state. The annual value of the exports and imports exceeds $15,000,000. This commerce is carried on with Montreal, principally by the way of lake Champlain and the Richelieu river, and by means of canals, navigation is also practicable with Albany and New York. The second steamboat ever built was the *Vermont*, launched on lake Champlain in 1809, or two years later than Fulton's attempt with the *Clermont* at New York.

Banks, etc.—On Oct. 31, 1896, there were 49 national banks in operation, with capital $6,985,000, deposits $8,688,420, and reserve $2,728,297, and 40 mutual savings banks, with depositors 103,281, deposits $32,170,743, and resources $34,991,347.

Railroads.—The railroads of the state are operated chiefly by the Central of Vermont, the Boston and Maine, and the Grand Trunk railroad companies. The total length of roads exceeds 1070 miles, of which about 870 miles are local. The capital of local roads is nearly $20,000,000, funded debt $10,000,000, total investment $31,500,000, cost of roads and equipments $26,000,000, and net earnings $1,600,000.

Religious Denominations, Education, etc.—The leading denominations numerically are the Roman Catholic, Congregational, Methodist Episcopal, Baptist, Protestant Episcopal, Universalist, and Free-will Baptist. V. forms a diocese of the P. E. church, and a bishop of the R. C. church is stationed at Burlington. Education, by law of 1887, is controlled by a state superintendent elected by the legislature, a co. board, consisting of one member from every town, and a co. salaried supervisor, chosen every 2 years by the co. board of education. Free public schools are maintained by means of state and local taxes and the income of a permanent school fund. The public school population is about 82,000, enrollment, 65,000; average daily attendance, 43,000; school houses, 2500; teachers, 3800; value of school property, $2,000,000; annual expenditure nearly $1,000,000.

Among the higher institutions are normal schools at Randolph, Johnson, Castleton, and Lawrenceville; Middlebury coll. (Cong.), Middlebury; Norwich univ. (P. E.), Northfield; the Univ. of Vermont (non-sectarian), Burlington; Montpelier seminary (M. E.), Montpelier; the State Agricultural coll. at Burlington; and the Vermont Episcopal institute, also at Burlington. The libraries in the state containing over 1000 vols. are 67 in number. The state library at Montpelier contains about 32,000 vols. The number of newspapers and periodicals published in 1897 was 86.

GOVERNMENT, ETC.—The capital is Montpelier. The gov., who holds office 2 years, receives a salary of $1500; the lieut. gov. receives $6 per day; the sec. of state (elected by the legislature) and treasurer, each $1700 yearly; the auditor, $2000. The executive veto is a suspensory act merely, and subject to the action of the next legislative session. The legislature consists of 30 senators and 245 representatives, each elected for two years since 1870, and each receiving $3 per day during a session. Legislative sessions are held biennially, open on the first Wed. in Oct., and are unlimited. General elections are held biennially on the first Tuesday of Sept. The qualifications for voting are—previous residence of one year in the state and 3 mos. in the town, and 30 days in precinct. The registration of voters is required. New ballot laws based on the Australian system (q.v.) were adopted in 1890. Wilful desertion or sentence to state prison for three years, absence, unheard of for seven years, are among the causes for divorce. Parties must have lived together in the state for one year. Residence required, one year. The judiciary of the state consists of a supreme court of 7 judges, chosen by the legislature for 2 years, each receiving $3000 salary; of a chancery court, which the supreme court judges also hold; of a co. court in each co.; of justices' courts in the several towns; and of probate courts in each probate district. The constitution provides for the meeting once in 7 years of a council of censors, who propose, if they desire to do so, changes in the constitution, which are acted upon subsequently by a convention called by them. The first of these councils met in 1785, and the fifteenth in 1883. Rents and profits of a wife's real estate and the interest of her husband in it, are exempt from execution for his debts, and can only be conveyed by her joining in the will. The wife may dispose of her property by will. The legal and only rate of interest is six per cent.; the penalty for usury is forfeiture of excess of interest. Judgments outlaw in eight years; notes, if under seal, in fourteen years, otherwise six years; open accounts, in six years. The state is entitled to two representatives in congress, and four electoral votes. The electoral votes have been cast as follows: 1792, Washington and Adams, 3; 1796, Adams and Pinckney, 4; 1800, Adams and Pinckney, 4; 1804, Jefferson and Clinton, 6; 1808, Madison and Langdon, 6; 1812, Madison and Gerry, 8; 1816, Monroe and Tompkins, 8; 1820, Monroe and Tompkins, 8; 1824, John Quincy Adams and Calhoun, 7; 1828, John Quincy Adams and Rush, 7; 1832, Wirt and Ellmaker, 7; 1836, Harrison and Granger, 7; 1840, Harrison and Tyler, 7; 1844, Clay and Frelinghuysen, 6; 1848, Taylor and Fillmore, 6; 1852, Scott and Graham, 5; 1856, Fremont and Dayton, 5; 1860, Lincoln and Hamlin, 5; 1864, Lincoln and Johnson, 5; 1868, Grant and Colfax, 5; 1872, Grant and Wilson, 5; 1876, Hayes and Wheeler, 5; 1880, Garfield and Arthur, 5; 1884, Blaine and Logan, 4; 1888, Harrison and Morton, 4; 1892, Harrison and Reid, 4; 1896, McKinley and Hobart, 4. In 1896 the assessed valuations were—real property $113,700,464, personal $60,996,759—total $174,697,233; tax rate, $1 per $1000; and in 1897 the total debt was $258,443, and resources, including cash on hand, $573,938. The state institutions are the prison at Windsor, the asylum for the insane at Waterbury, the soldiers' home at Bennington, the house of correction at Rutland, and the reform school at Vergennes. There are many denominational and local institutions, nearly all well endowed, and in or near Burlington.

POPULATION.—In 1790, 85,425; 1820, 235,966; 1840, 291,948; 1860, 315,098; 1880, 332,286; 1890, 332,422. There are 14 cos.; for pop. 1890, see Census Tables, vol. XV. The largest cities, 1890, were Burlington, 14,590; Rutland, 11,760; St. Albans, 7771; Brattleboro, 6862; Barre, 6812; St. Johnsbury, 6567; Bennington, 6391; and Montpelier, 4160. See histories by Hall, Thompson, and Miss Hemenway; Thompson's *Geography and Geology of Vermont.*

VERMONT, UNIVERSITY OF, in Burlington, on lake Champlain; chartered 1791. In 1865 the legislature gave the institution the avails of the land received from congress under the act of 1862, for the purpose of promoting instruction in agriculture and the mechanic arts, and since that time it has been known as the "University of Vermont and State Agricultural College." It is under the patronage of no religious denomination. Its original endowment consists mainly of leased lands, given partly by the state and partly by individuals. It has an invested fund (including the agricultural appropriation) of $246,000, and an annual income of $68,000. The university is beautifully situated on elevated ground, commanding a magnificent view of lake Champlain and the Adirondacks on the w., and of the Green mountains on the e. It has a library of 51,000 volumes, chemical, physiological, and botanical laboratories, a museum, a cabinet of art curiosities, and a large experimental farm. It embraces departments of arts, science (including engineering), agriculture, and medicine. Women are admitted to all departments except the medical. Professors (1896) in the colleges of arts and science, 21; in the medical college, 21. Students in all departments, 1897, 537; professors and other instructors, 52. Pres., Matthew Henry Buckham, D.D.

VERNAL GRASS, SWEET, *Anthoxanthum odoratum*, a grass very common in America and throughout Europe and the northern parts of the world generally, growing in meadows, woods, and pastures. It is about a foot high, with spiked oblong panicle, the flowers remarkable as having only two stamens. See illus., GRAIN, ETC., vol. VI.

VERNATION, in botany, a term employed to designate the manner in which the leaves are arranged in the leaf-bud. It corresponds with æstivation (q.v.) in the flower-bud. There are great differences in the vernation of plants, and these differences are characteristic not only of species but of genera, and even of natural orders, but the vernation of the same species is always the same. The vernation of plants is very interesting: in some the leaves are very simply placed together; in others they are most curiously folded, rolled, or plaited, and interlaced with each other.

VERNE, JULES, b. France, 1828; studied law at Paris; brought out a comedy in 1850 called *Les Pailles Rompues*, which was followed by *Onze Jours de Siège*, and several comic operas. He is chiefly known by his "scientific romances," of which the first, *Five Weeks in a Balloon*, appeared in 1863. Among his numerous later works may be mentioned: *A Journey to the Center of the Earth* (1872); *Twenty Thousand Leagues Under the Sea* (1873); *Around the World in Eighty Days* (1874); *Michael Strogoff* (1876); *Dick Sands, the Boy Captain* (1878); *Family Without Name* (1889); *The Purchase of the North Pole* (1890); *Le Château des Carpathes* (1892), etc. His *Le Docteur Ox* has been transformed into an opera.

VERNER'S LAW. A law of phonetics, supplementary to Grimm's Law (q.v.). It explains certain phonetic changes, which under Grimm's Law have to be regarded as exceptional. It was discovered by Karl Verner of Copenhagen, in July, 1875, and was first published in 1877 in Kuhn's *Zeitschrift*, vol. XXIII., page 97. Prof. W. W. Skeat gives the following statement of it in his *Principles of English Etymology:* "If the Aryan *k*, *t*, or *p*, immediately follows the position of the accent, it shifts regularly in Low German to *h*, *th*, or *f*; but if it precedes the position of the accent, it becomes (as it were by double shifting) *g*, *d*, or *b*."

VERNET, ÉMILE-JEAN-HORACE, a celebrated French painter of battle-pieces, in whom may be said to have culminated the talent of a family through several generations distinguished in the sphere of art. His grandfather, CLAUDE JOSEPH, born in 1714, was a native of Avignon. By Antoine Vernet, his father, also a painter, Claude Joseph was early initiated in art, and going at the age of 18 to Italy, he remained there 20 years. Toward the end of that period, much of which had been passed in struggle and privation, his reputation as a landscape and marine painter had become so high that he was invited to Paris by Louis XV., who assigned him apartments in the Louvre. Between this time (1752) and his death in 1789 he painted an immense number of pictures, one of his chief undertakings being a series of large pieces commissioned by government, representing the chief seaports of France. These were 15 in number, and are still to be seen in the Louvre, with many other of his best works. During his life he was held to be, in France, without a rival in his own department; and an honorable rank continues to be assigned him among the painters of his country. He married at Rome an English lady, a Miss Parker, by whom he had a son, ANTOINE-CHARLES VERNET, born at Bordeaux in 1758, and popularly known as Carle Vernet. Carle received his education, in the first instance, from his father, and afterward at the academy of Paris, where, in 1782, he gained the chief prize, which brought with it the privilege, of which he availed himself, of studying for some years in Rome. His subsequent success in Paris was great; he achieved the highest honors of the profession, became chevalier of the order of St. Michel, as also of the legion d'honneur, and died Nov. 17, 1835. He was especially celebrated as a painter of horses; but his chief works were battle-pieces on a large scale, chiefly commemorative of the triumphs of the great emperor, and, as such, amazingly popular with the Parisian public. The principal are: "The Battle of Marengo," "The Morning of Austerlitz," "The Emperor giving orders to his Marshals," "The Bombardment of Madrid," "Battle of Rivoli," "Entrance of Napoleon into Milan," and "Battle of Wagram."

The youth of HORACE VERNET, his son (born in Paris, June 30, 1789), was passed amid the tumults and anarchy of the revolution; and his general education was as irregular and incomplete as in such an element we might suppose it; but he had in his father a capable instructor in art, the hereditary genius for which very early became noted in him. It was the wish of his father that, as he had himself done, his son should go to study at Rome; but he failed in the competition for the traveling-pension for that purpose, given by the *académie des beaux arts*, and the scheme was necessarily abandoned. Undepressed by this disappointment, the young Vernet married and commenced his independent career as a painter, being then (1809) only 20 years of age. The *rôle* which he chose was that suggested at once by the previous success of his father and the military intoxication of the Parisian public. Young as he still was, he had served for some time as a soldier, not, so far as is known, with any special distinction, yet doubtless with such practical experience of the detail of a soldier's life in the field as would be found exceedingly available in his efforts for distinction of another kind. Whereas the treatment of military subjects by his father and others had been, hitherto, more or less of the conventional and so-called imaginative kind, more properly to be called imaginary, the

new aspirant, with his fuller sympathy and knowledge, sought for his effects in that serious rendering of truth which is the basis of all authentic imagination. In the halt, the bivouac, or the battle, the French soldier should be painted according to the veritable fact of the matter, as Vernet himself had seen, or could rigorously so conceive it. The success which rewarded this attempt at more earnest and truthful conception, was brilliant and instantaneous, his very first pictures of the kind—"The Dog of the Regiment and the Horse of the Trumpet," "Capture of the Redoubt," "Halt of French Soldiers," etc.—being received with an enthusiasm of favor accorded to those of no other artist. In 1812, to confirm this popular approval, the first-class medal was awarded to him; and in 1814 he had the title conferred on him, by the emperor, of chevalier of the legion d'honneur. The unrivaled popularity which he had thus at a bound achieved ever afterward remained with him; and the favor which he enjoyed from the emperor, whose victories he signalized on his canvas, was continued to him by the restored dynasty, whose sympathy with these favorite subjects, which, as occasion served, he continued as before to paint, could only be supposed imperfect. By Charles X. he was, in 1825, made officer of the legion d'honneur; and in the next year he was elected member of the Institute. In 1827 he was appointed director of the French academy at Rome, whither he went to reside. He remained there for several years; and on the withdrawal of the French legation, occasioned by the revolution of 1830, he was appointed to act as representative of his country at the Roman court.

With Louis Philippe, the services of Vernet were in especial request; and one of his most gigantic undertakings, the grand series of paintings in the Constantine gallery at Versailles, commemorative of the triumphs of the French arms in Algeria, was a task prescribed him by that monarch. In pursuance of this object he more than once visited Algeria; as, indeed, throughout his career he frequently became a traveler on similar professional errands. To the last, honors continued to flow upon him. In 1842 he was made commander of the legion d'honneur; and in the universal exposition of 1855 the grand medal of honor was awarded to him. He died Jan. 17, 1863. He left behind him no children; his only daughter, wife of the celebrated Paul Delaroche, having died in 1845.

Though he by no means exclusively confined himself to military subjects, as witness his well-known "School of Raphael," "Judith and Holofernes," and many others, it is on his consummate treatment of these that his fame mainly rests; and in this particular department, though he has many worthy competitors among his countrymen, no one of them can be said to equal him. With the utmost skill in effective composition, he combines in these works a surprising dash, vigor, and truthfulness; the movement and veritable fiery life of conflict is expressed in them with amazing effect. In the London international exhibition of 1862 some good specimens were exhibited.

VERNIER, a scale, by which linear or angular magnitude can be read off with a much greater degree of accuracy than is possible by mere mechanical division and subdivision, derives its name from its inventor, Pierre Vernier, "capitaine et chastellaine pour sa majesté au chasteau Dornans," who gave a description of it in a tract published at Brussels in 1631. The principle of this invention is essentially as follows: AB (fig. 1) is a portion of the graduated scale of an instrument showing divisions and subdivisions; *ab*, a small scale (called the *vernier*), made to slide along the edge of the other, and so divided that *ten* of its subdivisions are equal to *eleven* of the smallest divisions of the scale AB; then each division of the vernier is equivalent to $1\frac{1}{10}$ of a subdivision of AB; and consequently, if the zero-point of the vernier be (fig. 1, A) opposite 11 on AB, the 1 on the vernier is at $9\frac{9}{10}$ ($1\frac{1}{10}$ below 11), 2 on vernier is at $8\frac{8}{10}$ ($2\frac{2}{10}$ below 11), etc. Also, if the vernier be slid along so that 1 on it coincides with a division on the scale, then 0 on the vernier is *one* tenth above the next division on the scale; if 4 on the vernier coincide with a division on the scale, the 0 of the vernier is *four* tenths above a division. The vernier is applied to instruments by being carried at the extremity of the index limb, the zero on the vernier being taken as the index-point; and when the reading off is to be performed, the position of the zero-point, with reference to the divisions of the scale, gives the result as correctly as the mechanical graduation by itself permits, and the number of the division of the vernier which coincides with a division of the scale supplements this result by the addition of a fractional part of the smallest subdivision of the scale. Thus (fig. 1, B), suppose the scale-divisions to be degrees, then the reading by the graduation alone gives only a result between 15° and 16°; but as the 2d division of the vernier coincides with a graduation on the scale, it follows that the zero-point is $\frac{2}{10}$ of a division above 15°, and that, therefore, the correct reading is 15.2°. It will be at once seen that by merely increasing the size of the vernier, as, for example, making 20 divisions of it coincide with 21 on the scale, the latter may be read off to twentieths; and a still greater increase in the size of the vernier would secure further accuracy.

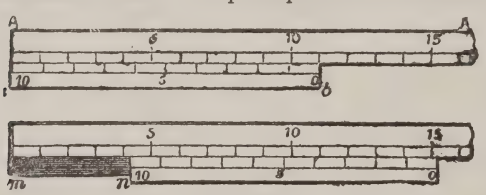

Fig. 1.

The above is the vernier as proposed by its inventor, and as it was employed for long after his time; but in the more recently constructed astronomical and geodesical instruments a vernier is employed which has one graduation *more* (fig. 2) than the corresponding portion of the scale. A little consideration will show that the only effect of this modification is to enable the vernier to be graduated toward the same direction as the scale, and thus save a little confusion in the reading off. In small instruments, or where the utmost accuracy is required, a small magnifying lens is fixed over the vernier, to enable the observer, in cases where no two graduations coincide (which is generally the case), to estimate the amount of error introduced by assuming that the two graduations which approach nearest to coincidence actually coincide.

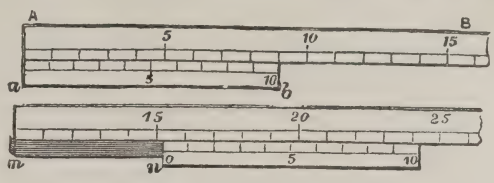

FIG. 2.

Of the various methods for subdivision which were in use before the introduction of the vernier, the most important were the *diagonal scale* (q.v.) and the *nonius*. The latter, so called from its inventor, Petrus Nonius (Pedro Nunez), a Portuguese mathematician, who described it in a treatise *De Crepusculis Olyssipone*, published in 1542, consists of 45 concentric circles described on the limb, and divided into quadrants by two diameters intersecting at right angles. The outermost of these quadrants was divided into 90, the next into 89, the third into 88, etc., and the last into 46 equal parts, giving on the whole a quadrantal division into 2,532 separate and unequal parts (amounting on an average to about 2′ intervals). The edge of the bar which carried the sights passed, when produced, through the center, and served, consequently, as an index-limb; and whichever of the 45 circles it crossed at a graduation, on that circle was the angle read off; for instance, if it cut the 7th circle from the outside at its 43d graduation, the angle was read off as $\frac{43}{44}$ of 90°, or 46° 4′ 17½″.

VERNON, a town in Tolland co., Conn., containing the city of Rockville (q.v.) and several villages. Pop. '90, 8808.

VERNON, a parish in w. Louisiana, having the Sabine river for its w. boundary, separating it from Texas; 1540 sq.m.; pop. '90, 5903. Co. seat, Leesville.

VERNON, a co. in w. Missouri, having the state line of Kansas for its w. boundary; 850 sq.m.; pop. '90, 31,505. Co. seat, Nevada.

VERNON, a co. in s.w. Wisconsin, having the Mississippi river for its w. boundary; 800 sq.m.; pop. '90, 25,111. Co. seat, Viroqua.

VERNON, a small t. of France, in the dep. of Eure, stands on the left bank of the Seine, 50 m. w.n.w. of Paris by the Havre, Rouen and Paris railway. It contains a handsome Gothic church and numerous picturesque old houses with wooden frameworks, and is the seat of some trade in grain. Pop. '91, 8288.

VERNON, EDWARD, 1684–1757, b. England; was with Hopson's expedition in 1702, and at the naval battle with the French in 1704. He became rear-admiral in 1708, and was returned to parliament in 1727. Having there declared that Porto Bello could be captured with 6 ships, he was sent out with that number of ships in 1739, and captured it with a loss of only 7 men. He was repulsed from Cartagena in 1741, and lost heavily by sickness. He was several times re-elected to parliament, and commanded on the Kent and Sussex coast in 1745.

VERNON, ROBERT, 1774–1849, born England. He acquired a fortune in mercantile pursuits, and spent large sums in collecting pictures, mostly by English artists. In 1847 he presented the more valuable part of his extensive collection to the British government. The Vernon collection includes 162 pictures, besides many busts and Gibson's group of Hylas and the nymphs. It is now in the South Kensington museum, and was formerly at Marlborough house.

VERNON-HARCOURT, LEVISON FRANCIS. See HARCOURT.

VÉRON, LOUIS DÉSIRÉ, 1798–1867; born Paris; educated at the imperial lyceum, became a physician, made a fortune by advertising a patent medicine through his connection with papers for which he wrote legitimist and ultramontane articles. In 1829 he founded the *Revue de Paris*. In 1831 he became manager of the grand opera, and brought out *Robert le Diable;* and in 1835 retired, having accumulated a considerable sum. He purchased in 1839 the *Constitutionnel*, and again made a lucky hit by publishing in it Sue's *Wandering Jew*, through which its circulation was enormously increased. He sold his paper after the *coup d'état*, supported the emperor, and became a member of the assembly. He published *Mémoires d'un Bourgeois de Paris, Quatre Ans de Règne*, and *Les Théâtres de Paris de 1806 à 1860*.

VERONA, a province of n. Italy, in the Austrian crown-land of Venice; 1061 sq. m.; estimated pop. '95, 434,325. It is bounded on the n. by the Tyrol; Vicenza and Padua on the e.; Rovigo and Mantua on the s.; Mantua and the lake of Garda on the w., the latter separating it from Brescia. Its surface is mountainous in the direction of the

Tyrol, containing Monte Baldo, 7200 ft. high, and in the s. is the great plain of the Po. It is drained by the Adige, the Tartaro or Castagnaro river, one of its branches, separating it from Mantua. The soil is fertile, producing wheat, corn, rice, potatoes, wine and fruit. Horse and cattle raising and silk-worm culture are among the industries, besides dyeing, tanning, and the manufacture of cotton and woolen fabrics, and glass. In the mountains near Verona is the village of Gargagnago, where Dante wrote part of his *Purgatorio*. Capital, Verona.

VERO'NA, an ancient and interesting city of northern Italy, in the province of the same name, stands on a plain at the foot of the hills which lie at the base of the Tyrolese mountains, 72 m. w. of Venice by railway. It stands on the Adige, by which it is divided into two unequal parts, connected by six bridges. The aspect of the town, and of the rich landscape around, is considered remarkably fine. Verona is a fortress of the first rank, a member of the famous Quadrilateral (q.v.), and has always been considered a place of strength since it was surrounded with walls by the emperor Gallienus, 265 A.D. Its modern fortifications are among the most extraordinary works of military engineering in Europe. After passing into the hands of the Austrians in 1815, it was greatly strengthened; and after 1849 they made every effort to render it impregnable. Of its many interesting edifices, the chief is the amphitheater, built, it is supposed, between the years 81 and 117 A.D. The building has been wonderfully preserved, the interior being still, to all appearance, complete. The lesser diameter of the building is 404 ft., that of the arena 156 ft.; and the edifice is calculated to have contained 22,000 people. This, as well as many of the other structures of the city, has a handsome appearance, owing to having been built of Verona marble. The Porta dei Borsari and the Arco dei Leoni are fine Roman gateways, both of the imperial age. The streets of Verona are wide, especially the Corso; there are four principal squares, of which the Piassa dei Signori contains the palace of the Della Scala and the superb Palazzo del Consiglio, the façade of which is adorned with bronze and marble statutes of celebrated natives of Verona, including Catullus, Pliny the younger, etc. The picture-gallery contains about 400 specimens, including a Madonna by Titian, and a full-length portrait and several works by Paul. Veronese. The cathedral, a Gothic structure of the 14th century, with choir and Romanesque façade of the 12th century, has a handsome porch, guarded by the celebrated paladins, Roland and Oliver. The more modern parts of the cathedral are exceedingly rich, and, among other excellent works of art, it contains a famous Assumption by Titian. Altogether, there are in Verona about 48 churches, many of them beautiful specimens of Gothic architecture, and containing valuable paintings and other art treasures. The palaces are also numerous and fine; and there are several theaters, hospitals, etc. Manufactures are not important, but there is considerable trade in silk, grain, oil and wine. Pop. of Verona (commune), '95, 73,200.

The early history of Verona is involved in obscurity, and there is some difficulty in determining whether it originally belonged to the Euganei or the Cenomani. It afterward fell into the hands of the Romans, and under the empire became one of the most flourishing cities in the n. of Italy. Constantine took it by assault in 312; Stilicho defeated the Goths here in 402. Charlemagne took possession of it, and made it the royal residence of his son, king Pepin. The Montagues, who were Ghibellines, lived here in perpetual and deadly enmity with the Guelf Capulets; and from the contentions that took place between these families, Shakespeare, drawing upon an Italian authority—has derived materials for his tragedy of *Romeo and Juliet*. In 1259 the town received Mastino della Scala as its ruler. In 1405 the city gave itself over to Venice, in order to free itself from its tyrants, who were alternately of the Scala, the Visconti, or the Carrara families. In 1866 it was ceded to Italy. See illus., VENICE, ETC.; ITALIAN ARCHITECTURE.

VERONA, a town in Oneida co., N. Y.; on Oneida lake, the Erie canal, and the New York Central and Hudson River railroad; 25 miles w. of Utica. It includes the village of Durhamville; has a high school, and nearly 20 churches; and is principally engaged in cheese-making. Pop. '90, 4535.

VERONESE, PAUL. See CAGLIARI.

VERON'ICA, the name of a supposed saint of the Roman Catholic church, whose history, and indeed whose historical existence, has been the subject of much controversy. According to the legend, Veronica was one of the women who met our Lord on his way to Calvary; and as he was sinking, overpowered by fatigue, under the weight of the cross, Veronica offered him her veil, to wipe the sweat from his brow, when, wondrous to tell, the divine features were miraculously impressed upon the cloth, and remained as a permanent picture of the face of our Lord. This miraculous picture is reported to have been preserved in Rome at St. Peter's church from about the year 700. Another, of similar appearance, is preserved at Milan; and many Catholic writers, among whom are the learned Mabillon and Papebrook, have supposed that whatever is to be said of the legend of the pious woman at Jerusalem, the name "Veronica" is but founded on an erroneous application of what in reality was meant to designate not the personage, but the picture, which was described as *vera icon* (Gr. *eikon*), "the true image" (i.e., of Christ). Other writers, however, are of opinion that Veronica is a real name, and designates a real personage, although probably erroneously applied in this legend. The picture has been frequently reproduced both in painting and engraving; the most celebrated of the former is one by the great Spanish painter Morales, surnamed "the divine"

from his favorite subject, which was the countenance of our Lord in the "Ecce Homo" and similar subjects.

VERONICA. See SPEEDWELL.

VERPLANCK, GULIAN CROMMELIN, LL.D., 1786–1870; b. New York; graduated, Columbia college, 1801; admitted to the bar; spent several years in Europe; member of the legislature, 1820, and chairman of the committee on education; professor of the evidences of Christianity in the Episcopal theological seminary, New York, 1822; member of congress, 1825–33; state senator for several years; vice-chancellor of state university; president of the New York board of emigration commissioners, 1846–61. He published, among other works, *Evidences of Revealed Religion; Essay on the Doctrines of Contracts; Addresses and Discourses;* and edited *Shakespeare's Plays* with his *Life,* 3 vols.

VER'RES, a Roman, elected pretor in 74 B.C. and by lot became *prætor urbanus.* At the expiration of his term of office he was appointed governor of Sicily, the richest province of the republic. Here he was guilty of great oppression and extortion, and at the end of his three years' administration was accused by the Sicilians. Cicero managed the prosecution, and Hortensius the defense. Cicero had prepared six orations, but at the close of the first so clear was the guilt of Verres that, without awaiting his sentence, he fled to Masilla, remaining in exile 27 years, and living in affluence on his ill-gotten gains. He perished in the proscription of Antony.

VERSAILLES, a celebrated city of France, and long the residence of the French court, (Louis XIV., XV., and XVI.), capital of the dep. of Seine-et-Oise, stands on a plain, 11 m. s.w. of Paris by railway. A fine avenue, which forms part of the road from Paris, divides the town into two parts. The town is of remarkably regular construction, consisting of long and straight streets, crossing at right angles. Versailles, a city more of pleasure than of industry,—long accustomed to find its sustenance in the expenditure of a luxurious court, and subsequently a place of residence for many foreigners attracted hither by the salubrity of the climate, the fine promenades, and the economy of living, as compared with that in Paris—has few manufactures, and little trade. It is the see of a bishop, and contains an extensive public library, many palatial edifices, public fountains, spacious squares, and elm-planted avenues; and when taste in architecture and in landscape-gardening was more formal than at the present time, the town was esteemed the handsomest in Europe. The great attraction of Versailles is its palace, and the history of this structure may be said to be the history of the town. The site occupied by the palace is known to have been that of the ancient priory of St. Julien, the chronicles of which place the date of the building in the early times of the Capetan monarchy. Later, the priory became a feudal stronghold, and its first superior, *Hugo de Versaliis,* lived in the 11th century. In 1570 the manor belonged to Martial de Léoménie, one of the victims of St. Bartholomew. The building was converted by Louis XIII. into a château; and Louis XIV. devoted enormous sums to its embellishment, or rather reconstruction. Louis XV. altered the arrangement of the interior, and meditated alterations that would have changed the whole character of the edifice, but which he was unable to carry out from want of money. Under Louis XVI., Versailles continued to be one of the usual residences of the court down to the period of the revolution, which great event had its beginning here in the meeting of the states-general, in May, 1789. Louis Philippe transformed the palace of Louis XIV. into a museum, to contain trophies of the victories of France. The approach to the palace is by the *Place d'Armes* and the *Cour d'Honneur,* in the latter of which is a large equestrian figure of Louis XIV., and other statues. The entire length of the palace is nearly 1400 feet. The collections embrace pictures of events in French history, portraits of French heroes, etc. The most interesting are the pictures of David which illustrate the career of Napoleon, and those by Horace Vernet. The gardens, with their broad terraces and long alleys, are imposing, but formal; the fountains are on the grandest scale. From the middle of Sept., 1870, till the conclusion of peace in 1871, Versailles was the center of all the operations of the Germans. On Sept. 20, king William and the crown-prince entered the town; and there, on Jan. 18, 1871, the former was proclaimed emperor of Germany. On Jan. 28, the capitulation of Paris was signed in Versailles; after the peace, it became the seat of the national assembly and government till 1880, and was the headquarters of the army during the commune. Pop. '81, 48,324; '91, 51,679.

VERSE (Lat. *versus,* from *verto,* to turn, a turning of the plow, a furrow, a row; a line in writing and in poetry), a section or group of meters written in one line. See METER, RHYME. The term verse is often erroneously applied to a group of lines or verses, which is properly a stanza. Verse is often used to signify metrical composition.

VERSECZ, a t. of Hungary in the co. Temes, situated at the foot of the Versecz mountain, 45 m. s. of Temesvár by railway. It is the seat of a Greek non-united bishop. The chief industry is the production of silk, wine, and rice. Pop. '90, 21,819.

VERSICLE (Lat. *versiculus,* a little verse), a short verse in the service, which is spoken or chanted by the priest or minister alternately with a "response" by the people.

VERSIONS. See BIBLE.

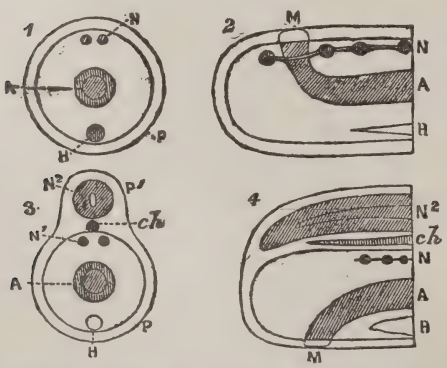
VERST, or WERST, in Russian, *versta*, an itinerary measure, equivalent to 1166⅔ yards, or about two-thirds of an English mile.

VERT. See HERALDRY.

VERTEBRÆ. See SPINAL COLUMN and SKELETON.

VERTEBRATA, the highest and most important of the animal sub-kingdoms, characterized by the universal presence of a backbone, composed of a varying number of small bones called vertebræ (see SKELETON and SPINAL COLUMN), which at once serve for the general support of the other parts, and for the protection of the central part of the nervous system (the brain and spinal cord) in a closed cavity in the interior.

We shall notice first the developmental and then the structural peculiarities of the vertebrates. Like the members of the other sub-kingdoms, the vertebrates begin in a semi-fluid nitrogenous substance called plasma, which separates itself (or differentiates, as it is scientifically termed) into albumen, fibrin, primary membrane (the lemma of Owen), nuclei, and cells, in which form, says the above-named physiologist, "the individuality of the new organism first dawns as a nucleated germ-cell, or germinal vesicle." The formation of yolk by the evolution of albuminous granules and oil-particles from the plasma, and the development of an outer layer of membrane, complete the unimpregnated egg. For further development, another principle, the spermatozoon, or product of the sperm-cell, is required. Its reception by the egg is followed by the formation of a germ-mass, which is formed by consecutive divisions, cleavages, or segmentations of the impregnated center, which incorporates more or less of the yolk. Thus far there is no difference between the vertebrate and invertebrate germ. The next step, to use the words of Professor Owen, "impresses upon the nascent being its *vertebrate* type." As has been shown in the article DEVELOPMENT OF THE EMBRYO, the parietal portion of the germ becomes raised up on each side into a ridge, so that a long groove or furrow is formed between these parallel ridges (see p. 774 in above-mentioned article); and the margins of these subsequently uniting with one another, constitute a tube, in the interior of which the vertebrate cerebro-spinal nervous centers are developed. In the mean time, the margins of the germs extend downward over the yolk till they meet and form the abdominal cavity. Hence in the vertebrates there are developed from the *chorda dorsalis*, or *notochord* (see DEVELOPMENT), "a pair of plates 'neurad,'* to inclose the nervous axis, and a pair of plates 'hæmad,'† to inclose the vascular axis and organs of vegetative life. Flesh and skin co-extend with the inclosing plates. This formation of two distinct parallel cavities—neural and hæmal—under symmetrical guidance, in the vertical or 'neuro-hæmal' direction, with a repetition of parts on the right and left sides, establishing transverse or 'bi lateral' symmetry, constitutes the chief developmental characteristics of the vertebrate animal."—Owen's *Anatomy of Vertebrates*, vol. i. p. 2. The accompanying diagrams, which we have borrowed from Professor Huxley's *Elements of Comparative Anatomy*, may tend to render this subject more intelligible. In the invertebrates, merely a single saccular or tubular investment is formed, which incloses all the viscera; so that, provided we select one high enough to possess a heart and nervous system—the transverse and longitudinal sections would be represented by 1 and 2, while P represents the parietes, or wall of the body, A the alimentary canal, M the mouth, H the heart, and N the nervous centers. "It will be observed," says Professor Huxley, "that the alimentary canal is in the middle, the principal centers of the nervous system upon one side of it, and the heart upon the other. In none of these animals, again, would you discover in the embryonic state any partition formed by the original external parietes of the body between the nervous centers and the alimentary canal."—*Op cit.*, p. 59. But the vertebrate, after it has passed through its very earliest stages of development, is, as we have seen, not a single, but a double tube; and the "two tubes are separated by a partition, which was, primatively, a part of the external parietes of the body, but which now lies in a central position between the cerebro-spinal nervous centers and the alimentary canal. Hence a transverse section of any vertebrated animal may be represented diagramatically by fig. 3, where, for the most part, the letters have the same signification as in the foregoing case, but where P′ denotes the second or cere-



Diagrams representing generalized sections of one of the higher invertebrates (1, 2) and of a vertebrate (3, 4).

1, 3, transverse; 2, 4, longitudinal section; A, alimentary canal; H, heart; P, parietes of the body; P′, parietes of neural canal; N, nervous centers of invertebrate; N′, sympathetic, and N², cerebro-spinal centers of vertebrate; *ch*, notochord; M, mouth.

* Backward in man, upward in beasts.

† Forward in man, downward in beasts.

bro-spinal tube. The visceral tube (P) contains, as in the case of the invertebrate animal, the alimentary canal, the heart, and certain nervous centers belonging to the so-called sympathetic system. This nervous system and the heart are situated upon opposite sides of the alimentary canal, the sympathetic corresponding in position and in forming a double chain of ganglia with the chief nervous centers of the invertebrata; so that the cerebro-spinal tube appears to be a superaddition—a something not represented in the invertebrate series. In close connection with the profound difference between the chief nerve-centers of the vertebrate and the invertebrate, is another remarkable structural contrast. In all the higher invertebrates, with a well-developed nervous system, the latter is perforated by the gullet, so that the mouth is situated upon the same side of the body as the principal masses of the nervous system; and some of the ganglia of the latter lie in front of, and others behind the esophagus. A longitudinal section of such an animal may therefore be represented by fig. 2. A similar section of a vertebrated animal shows, on the contrary, the chief center of the nervous system not to be perforated by the esophagus, the latter turning away from it, and opening upon the opposite side of the body (fig. 4)."—*Op. cit.*, p. 60. No structures having any analogy to the *chorda dorsalis*, or *notochord*, or to the *visceral arches* and *clefts* (see SKELETON), are to be found in the embryonic condition of any of the invertebrates.

Passing on from the developmental to the structural differences, we universally have the vertebral column and the nervous centers, consisting of brain and spinal cord; and the organs of the five senses are usually present. All possess a distinct vascular system, containing blood, with red and white corpuscles in suspension, and in all (with the solitary known exception of the *amphioxus*, or lancelet), there is a compact muscular heart of two or more cavities, and provided with valves. The breathing organ communicates with the pharynx. The alimentary canal has two apertures, usually at opposite ends of the trunk, the mouth or reception aperture never being formed of modified limbs, or working horizontally, as in the *articulata*, but provided with two bony jaws, placed one above the other, and acting vertically.

All vertebrates possess a hepatic portal system, by which the blood of the alimentary canal is collected into a portal vein which ramifies through the liver. The limbs may be totally absent, or one or two pair, never more. The muscles surround the bony levers on which they act, and thus, under the influence of the will, move the limbs and other parts. The sexes are distinct.

Comparative anatomists differ in their division of the vertebrates into classes, and as to the best basis of classification. Prof. Owen, in his *Anatomy of Vertebrates*, admits of only four classes, viz., fishes, reptiles, birds, and mammals; whereas Milne-Edwards, Huxley, and many of our leading authorities, separate the amphibians from the reptiles, and assign them a class by themselves. Prof. Owen, after describing the modifications of the piscine, reptilian, ovian, and mammalian types, observes that the vertebrates might be binarily divided into oviparous and viviparous; into anallantoic or branchiate, and allantoic or abranchiate; into *hematothermal* (Gr. *haima*, blood, *thermos*, hot) having four-chambered heart, spongy lungs, hot blood, and *hematocryal* (Gr. *haima*, blood, *cruos*, cold), having less perfect breathing organs, less complex heart, with cold blood; and adopts the latter. Huxley, on the other hand, after noticing the division of the vertebrates into *branchiate* and *abranchiate*, and pointing out the non-homogeneous character of the abranchiates—mammals being so strongly separated from birds and reptiles—suggests the removal of them to an independent position. "Thus," he observes the classes of the *vertebrata* are capable of being grouped into three provinces: (1) The ICHTHYOIDS (comprising fishes and *amphibia*), defined by the presence of branchiæ at some period of existence, the absence of an amnion, the absence of a rudimentary development of the allantois, nucleated blood corpuscle, and a parasphenoid bone in the skull; (2) the SAURIANS, defined by the absence of branchiæ at all periods of existence, the presence of a well-developed amnion and allantois, a single occipital condyle, a complex mandibular ramus, articulated to the skull by a quadrate bone, nucleated blood corpuscles, and no parasphenoid, comprising reptiles and birds: and (3) the MAMMALS, devoid of branchiæ, and with an amnion and an allantois, but with two occipital condyles, and a well-developed basi-occipital, and no parasphenoid, a simple mandibular ramus, articulated with the squamosal, and not with the quadratum, with mammary glands, and with red non-nucleated blood corpuscles."—*Op. cit.* p. 74.—For further details, the reader may consult Stannius's *Comparative Anatomy of the Vertebrata* (in German), Wagner's *Comparative Anatomy of the Vertebrata*, translated from the German by Tulk; the works of Huxley and Owen quoted in this article; and the special departments of Cuvier's *Règne Animal*, and Blanchard's *L'Organisation du Règne Animal*, Balfour's *Embryology* See ZOÖLOGY.

VERTEBRATES, ANIMAL (see VERTEBRATA). The following is a brief synoptical classification of the principal divisions of the vertebrate branch of the animal kingdom, including, with few exceptions, only classes and orders, and referring to various articles throughout this work, for a description of families, genera, and species. The vertebrate animals include only one subkingdom, *vertebrata*, which may be briefly defined as comprising animals having a body composed of a number of segments placed on a longitudinal axis, and a nervous system chiefly dorsal. A transverse and

vertical section of the body exhibits two cavities completely separated from each other by a partition. The dorsal, or cerebro-spinal nervous system, is contained in the superior or dorsal cavity; the ventral, or inferior cavity, contains the alimentary canal, the heart, and hemal system, and also a nervous system, called the sympathetic, or ganglionic, consisting usually of a double chain of ganglia, connected by nerve fibers, which also contain filaments derived from the cerebro-spinal system. During the embryonic condition of all vertebrates the center of the partition is occupied by an elongated, cellular, cylindroidal mass, called the notochord, or chorda dorsalis, which in some vertebrata continues through life; but it is usually replaced by a partly fibrous and cartilaginous, and partly bony, jointed structure, called the vertebral column. See DEVELOPMENT OF THE EMBRYO. Another characteristic of vertebrates is that the alimentary canal never penetrates or passes through any part of the nervous system as it does in invertebrates, the gullet in them passing through an œsophagal nerve collar. In all vertebrates, moreover, that part of the wall of the visceral tube or cavity which lies at the sides of, and immediately behind, the mouth, has, at a certain stage of development, a series of parallel thickenings, transverse to the axis of the body, which are called the visceral arches, and between these arches there are clefts by which the pharyngeal cavity temporarily communicates with the exterior. Nothing corresponding to these arches and clefts is found in the invertebrata. A vertebrate may have no articulated limbs, and it never has more than two pairs, which always have an internal skeleton to which the muscles are attached. Invertebrates usually have a greater number of limbs, and the muscles are attached to an exo-skeleton. All vertebrates, except the lancelet, have a single valvular heart, and a hepatic portal system, the blood from the alimentary canal being in part returned to the heart by a *portal vein* which ramifies through the liver; and there is also a peculiar system of vessels, called the *lacteal system*, which is an appendage to the venous system of blood-vessels, and consists of a series of vessels which take up the products of digestion, and while they are undergoing partial elaboration, convey them to an entrance into the venous circulation, where they mingle with the venous blood, soon to be sent to the lungs. In regard to the cerebro-spinal and sympathetic nervous systems, the former constitutes by far the greater portion, and in all except the lowest members there is a well-marked separation into spinal cord (*myelon*) and brain (*encephalon*), the proportion of one to the other differing very greatly. The nerves which arise from the cerebro-spinal axis are symmetrically disposed on the two sides of the body, and are chiefly concerned in sensation and motion, and the cerebro-spinal centers also are symmetrically formed, while the sympathetic system is more or less unsymmetrical in form and distribution, and is chiefly concerned in regulating the functions of digestion, circulation of the blood, and lymph, and, to an undetermined extent, respiration.

The cerebro-spinal system is commonly called the system of *animal* life, while the sympathetic system is called that of organic or *vegetative* life, as it has nothing to do, so far as can be ascertained, with voluntary motion. It may be remarked here, however, that the physiology of the nervous system, in some respects, is far from being perfectly understood, although almost innumerable important facts have been ascertained. Although the articulata, such as insects and crustaceans, are particularly associated with the possession of an exo-skeleton exclusive of an endo-skeleton, such as belongs to vertebrates, still many of the latter have an exo-skeleton, formed by a hardening of the outer layer of the integument. The integument is composed of two layers, an outer non-vascular *epidermis*, and a deeper vascular *dermis*, and from these may be developed an epidermal, or a dermal skeleton. The epidermal skeleton is always horny, and is represented under various forms, as in the hairs of animals, the feathers of birds, the scales of serpents and lizards, and the plates of tortoises and turtles. The dermal skeleton may be either horny or bony.

Divisions of the Vertebrata.—This great subkingdom is naturally divided into the five great classes of fishes, amphibians, reptiles, birds, and mammals, or *pisces*, *amphibia*, *reptilia*, *aves*, and *mammalia*. As has been mentioned in the preceding article, however, there are differences of opinion in regard to the relations of members of these classes, so that there is disagreement when it is undertaken to group them into larger sections. The fact that all agree in recognizing the above five divisions, while many high authorities disagree in regard to more general groupings, suggests a question as to the necessity of a more general division.

CLASS I., PISCES.—Vertebrate animals which are provided with gills throughout their whole life. The heart, when present, consists, except in *dipnoi*, of a single auricle and a single ventricle, and the blood is cold. The limbs, when present, are in the form of fins, or expansions of the integument, and there is neither an amnion nor an allantois in the embryo, unless the latter is regarded as represented by the urinary bladder. In most fishes there is a peculiar line of scales called the *lateral line*, in which each scale is perforated by a tube leading to a longitudinal canal which runs along the side of the body and is connected with cavities in the head. It has been thought that its chief office was to secrete the mucus which covers the body of the fish, but this idea is now regarded as probably erroneous, and it is generally believed that it has a function connected with the sense of touch. The osseous system in fishes varies widely. In the

lancelet the spinal cord is supported by little more than a gelatinous notochord; in others the skeleton remains cartilaginous, or it is partly cartilaginous and partly osseous, and in others it is entirely converted into bone, although the bone of fishes is unlike the bone of mammals and other vertebrates. The vertebral column of a bony fish has the following characteristics: the vertebræ of which it is composed are hollow at both ends, or *amphicœlous*, and the cup-like margins are united by ligaments, while the cavities between the vertebræ are filled with an elastic gelatinous substance, the remains of the notochord, which acts as a ball and socket joint, well adapted to the great mobility required in these animals. The kidneys are generally greatly developed, forming two elongated organs situated beneath the spinal column and extending along the whole length of the abdominal cavity. The ureters often dilate and form a kind of bladder, the doubtful representative of the allantois above mentioned. The nervous system of fishes is of an inferior type, the brain being very small and principally consisting of ganglia devoted to the special senses. The essential portion of the organ of hearing, the *labyrinth*, is present in most fishes, but there is no compartment external to this having an outer communication, and none is required, as in air breathing animals.

In regard to the divisions of the class *pisces* they are arranged, according to prof. Huxley, into six orders, the subdivisions of which are according to the classification of prof. Owen:

Order 1, *Pharyngobranchii.*—This order includes but a single species, the *amphioxus lanceolatus*, or lancelet (q.v.).

Order 2, *Marsipobranchii* (q.v.).—Body cylindrical, worm-like, and without limbs; skull cartilaginous, and having no lower jaw; notochord persistent; gills sac-like and not furnished with cilia. See Lamprey and Hag.

Order 3, *Teleostei.*—This order comprises most of those fishes which have a well-ossified endo-skeleton, and nearly corresponds to Cuvier's division of *osseous* fishes. See Teleostei; also Acanthopterygii, Alewife, Anabasidæ, Anableps, Archer-fish, Balistes, Bass (*labrax*), Bib, Blue-fish, Black-fish, Bonito, Bony-pike, Burbot, Bull-trout, Candle-fish, Carp, Climbing-perch, Clupesocidæ, Charr, Coal-fish, Chub, Cod, Cottus, Chætodontidæ, Cyprinidæ, Cyprinodontidæ, Dab, Dace, Dentex, Dory, Drum-fish, Esocidæ, Fighting-fish, Fistularidæ, Flat-fish, Flounder, Flying-fish, Gold-fish, Groundling, Gudgeon, Gymnetrus, Gymnotus, Haddock, Halibut, Holocanthus, Herring, Labridæ, Lampris, Leaping-fish, Leuciscus, Ling, Mackerel, Malacopterygii, Mango-fish, Mullet, Opah, Osphromenus, Osteoglossidæ, Ostracion, Paralepididæ, Perch, Percopsidæ, Pharyngognathi, Pike, Pike-perch, Pilchard, Pilot-fish, Pipe-fish, Plaice, Pleuronectidæ, Pogonias, Pollack, Polypterus, Remora, Roach, Rockling, Round-fish, Salmon, Salmonidæ, Saury-pike, Scabbard-fish, Scad, Scomberesocidæ, Scomberidæ, Sea-pike, Shad, Sheepshead, Siluridæ, Smelt, Sole, Sparidæ, Sphyrænidæ, Sprat, Sword-fish, Star-gazer, Tautog, Tomcod, Trout, Trunk-fish, Tunny, Turbot White-bait, White-fish, Whiting, Wolf-fish, Wrasse.

Order 4, *Ganoidei.*—This is an important order, but is represented more by extinct than by living forms, reaching far back in geological time, and furnishing many of the most interesting studies in paleontology. At the present epoch the order consists of only seven genera, viz.: 1, *lepidosteus;* 2, *polypterus;* 3, *calamoichthys;* 4, *amia;* 5, *acipenser;* 6, *scaphirhynchus;* 7, *spatularia;* all confined to the northern hemisphere, and principally to fresh water. They have the following characteristics: The endo-skeleton is only partially ossified, most of the vertebral column remaining cartilaginous during life, especially in the paleozoic forms, in which the notochord is often permanent. The skull has distinct cranial bones, and there is a lower jaw-bone. The exo-skeleton is in the form of ganoid scales (see Ganoid Fishes) or spines. There are usually two pairs of lateral fins, supported by fin rays, the first rays being generally in the form of strong spines. The pectoral arch is furnished with a clavicle, and the ventral fins are close to the anus. The caudal fin is generally unsymmetrical (heterocercal). There is always an air-bladder, which is provided with an air-duct, and is often cellular. The intestine is furnished with a spiral valve. The gills and opercular apparatus resemble those of the teleostei. The heart has one auricle and one ventricle, and the base of the branchial artery is dilated into a *bulbus arteriosus*, which is rhythmically contractile, and has a coat of striated muscular fibers and several transverse rows of valves. The most important of these characteristics is the partially ossified condition of the endo-skeleton, but which varies as to extent of ossification. In most of the older forms the notochord remains, no vertebral centra are developed, and the skull is cartilaginous and protected by ganoid plates; but even in these the outer parts of the vertebræ are often ossified. In others the vertebræ are biconcave or amphicœlous, as in teleostei. In one ganoid, however, the bony pike or *lepidosteus*, the vertebræ are opisthocœlous, or concave behind and convex in front. This is regarded as the highest point of development in the vertebral column of any fish, and as being more reptilian than piscine. The ganoid scales are composed of two layers, an inferior one of bone, and an outer one of enamel, similar to that of teeth, and called *ganoine*. The most typical form of these plates is rhomboidal, and placed edge to edge without overlapping, articulated by means of distinct processes, and forming oblique rows. Sometimes, however, the plates or scales

are circular, and overlap each other as in ordinary fishes. In the sturgeon they are detached dermal plates of true bone. Both pectoral and ventral fins are usually present, the ventrals being placed far back. In some forms the paired fins are arranged so as to form a fringe around a central lobe, and for this reason Prof. Huxley has arranged them in a distinct section called *crossopterygidæ* (fringe-finned). The same form is found in the sixth order, *dipnoi*. The caudal fin varies in form, being sometimes homocercal, and sometimes heterocercal, and therefore, in this respect, the ganoids are midway between the bony fishes (teleostei) and the sharks and rays. Like the bony fishes, the ganoids have free, pectinated gills attached to branchial arches and inclosed in a branchial chamber protected by a gill-cover, and closed by a branchiostegal membrane, usually supported by branchiostegal rays. The sturgeon (*acipenser*) and *polypterus* are furnished with spiracles on the top of the head, communicating with the mouth. The order *ganoidei* may be divided into two sections, *lepidoganoidei*, in which the body is furnished with scales of moderate size, and the endo-skeleton is more or less perfectly ossified; and *placoganoidei*, in which the skeleton is imperfectly ossified, and the head and more or less of the body are protected by large ganoid plates, often united by sutures. See Bony-pike, Cephalaspis, Polypterus, Pterichthys, and Sturgeon.

Order 5, *Elasmobranchii*.—This order is equivalent to the *selachia* of Müller, the *placoids* of Agassiz, and the *holocephali* and *plagiostomi* of Owen, and to the most typical portion of the cartilaginous fishes of Cuvier. It may be briefly defined by the following characters: The skull and lower jaw are well developed, but there are no distinct cranial bones, the skull consisting of a single cartilaginous box, without sutures; vertebral column sometimes composed of distinct vertebræ, sometimes cartilaginous. The exo-skeleton is composed of placoid granules, tubercles, or spines; two pairs of lateral fins, supported by cartilaginous fin rays, the ventral fins far back; pectoral arch has no clavicle; heart consists of one auricle and one ventricle, and a *bulbus arteriosus* rhythmically contractile and having a coat of striated muscular fibers, and several transverse rows of valves. The gills are pouch-like, differing materially from those in teleostei and ganoidei. In the sharks and rays the branchial arches are fixed, and the branchial chamber is divided into a number of distinct pouches, and each partition supports a series of branchial laminæ attached to each side like the leaves of a book. The separate pouches open into the pharynx by a separate slit, and communicate externally with the water by a separate aperture placed on each side of the neck. There is, therefore, no gill-cover and no branchiostegal membrane or rays. The elasmobranchii are divided into two sub-orders: *holocephali*, in which the mouth is terminal, and there is only a single gill-slit, and the *plagiostomi*, in which the mouth is transverse and placed on the under surface of the head, and there are several gill-slits on each side of the neck. The suborder holocephali includes several curious fishes, of which the only living forms are the chimeridæ. See Chimæra. There are several fossil representatives in the secondary and tertiary formations constituting the genera *edaphodus*, *elasmodus*, and *ischiodus*. The suborder plagiostomi includes the sharks (q.v.) and the rays (q.v.).

Order 6, *Dipnoi*.—This order includes only certain kinds of mud-fishes, *lepidosiren* and *ceratodus*, and is considered by some to be a connecting link between the fishes and the amphibia. See Lepidosiren. The lepidosiren formerly constituted the lowest order of amphibia, but most authorities now place it as the highest order among the fishes. The body is fishlike in form, the skull has distinct cranial bones and a lower jaw, and the notochord is persistent; there are no vertebral centra nor an occipital condyle. The exo-skeleton in living types is composed of overlapping cycloid scales, but the fossil forms have ganoid scales. The dipnoi resemble the amphibians in having a heart with three cavities—two auricles and one ventricle—and in having true lungs and a trachea and glottis, the blood returning to the heart by a distinct pulmonary vein.

Distribution of Fishes in Time.—The oldest representatives of fishes are ganoids, and four genera are found in the upper silurian rocks. Their maximum development was in the Devonian red-sandstone. The stureonidæ commenced their existence in the mesozoic formations (lias) and a true sturgeon, *acipenser toliapicus*, in the eocene. The elasmobranchii (sharks and rays) commenced at the close of the upper silurian in the upper Ludlow rocks. Their remains consist of spines and fin rays, from which the genus *onchus* has been established. Portions of *shagreen* have been referred to the genus *sphagodus*. The true sharks are represented in the later mesozoic deposits, but they are mostly found in the tertiary formation, several genera in the eocene. The true rays, however, are older than the true sharks, probably beginning in the carboniferous rocks. Until recently the dipnoi were not known to be represented in past time, but the triassic and Jurassic teeth upon which Agassiz founded his genus *ceratodus* are now regarded as belonging to this order. The teleost fishes first made their appearance in the cretaceous formation, toward the end of the mesozoic epoch, but after this they are the chief representatives of the whole class of fishes, and they now seem to have reached their greatest development.

Class II., Amphibia.—This class comprises the frogs and toads, the salamandroids, the cæciliæ, and the extinct labyrinthodonts. See Amphibia and Batrachia.

Class III., Reptilia.—The reptiles are divided into ten orders, four of which are represented by living forms, and six of which are extinct. The living orders are, 1, *chelonia*, the tortoises and turtles; 2, *ophidia*, the serpents; 3, *lacertilia*, the lizards; 4,

crocodilia, the crocodiles and alligators. The extinct orders are 5, *ichthyopterygia;* 6, *sauropterygia;* 7, *anomodontia;* 8, *pterosauria;* 9, *dinosauria;* 10, *theriodontia.*

Order 1, *Chelonia* (q.v.).—See also Tortoise, Turtle, and Snapping-turtle.

Order 2, *Ophidia*—comprising the snakes and serpents. See Serpents, Boa, Cobra-di-Capello, Coluber, Elaps, Lachesis, Puff-adder, Python, Rattlesnake, Toxodontia, Trigonocephalus, and Viperidæ.

Order 3, *Lacertilia*—comprising those animals commonly known as lizards and some serpent-like forms, and having the following general characters: Two pairs of well-developed limbs as a rule, but there may be but one pair, and sometimes there are no limbs; but a scapular arch is always present. There is generally an exo-skeleton in the form of horny scales, like those of snakes. The vertebræ of the dorsal region are concave in front, but rarely concave at both ends. There is a single transverse process at each side of a vertebra, and the heads of the ribs are simple and undivided. There is either no sacrum, or the sacral vertebræ rarely number more than two. The teeth are not set in distinct sockets, except in some extinct forms, and the eyes are usually furnished with movable eyelids. The heart contains two auricles and a ventricle, the latter being partially divided by an incomplete partition. The order lacertilia are often grouped with the crocodilia, under the name sauria, and this is a convenient term to designate all reptiles which resemble the typical lizards. All the lacertilians have teeth, which are always simple; sometimes sharp and conical, as in *monitor;* sometimes blade-like, with serrated edges, as in *iguana;* and sometimes with rounded, crushing crowns. The order is sometimes divided into three sections, according to the structure of the tongue. In the first section the tongue is long and can be protruded, as in serpents; in the second section, including the geckos, the tongue is thick and fleshy, and not protrusible; in the third section, which contains the chameleons, the tongue is long, protrusible, and worm-like, with a clubbed extremity. See Chameleon, Lizard, Gecko, Iguana, and Mososaurus.

Order 4, *Crocodilia.*—This is the highest order of living reptiles, and includes the crocodiles (q.v.), alligators (q.v.), and gavials (q.v.). See also Jacare and Cayman.

Extinct Orders of Reptiles.—Order 5, *Ichthyopterygia*, Owen (*Ichthyosauria*, Huxley). See Ichthyosaurus.

Order 6, *Sauropterygia*, Owen (*Plesiosauria*, Huxley). See Plesiosaurus.

Order 7, *Anomodontia*, Owen (*Dicynodontia*, Huxley). The prominent characters of this order are in the jaws, which are regarded as having been encased in horn, forming a kind of beak like that of chelonians. In the genus *oudenodon* both jaws were probably without teeth, but in the other genus, *dicynodon*, the upper jaw was furnished with two long tusks. The pectoral and pelvic arches were very strong, and the limbs well developed and adapted to walking and not swimming. These forms are found in the triassic strata of s. Africa and India.

Order 8, *Pterosauria.*—This order includes the extraordinary group of flying reptiles belonging to the mesozoic epoch. See Pterodactyl.

Order 9, *Dinosauria.*—Most of these animals were gigantic, and supposed by some to have had affinities with the pachydermatous mammals. The skin was sometimes naked, sometimes having an exo-skeleton of bony shields like those of crocodiles; anterior trunk-ribs double-headed; teeth set in distinct sockets. There were always two pairs of limbs, very strong, and furnished with claws. In some the fore limbs were small compared to the hind limbs. See Dinosauria, Hadrosaurus, Hylæosaurus, Iguanodon, Megalosaurus, and Titanosaurus.

Order 10, *Theriodontia.*—This order was established by prof. Owen for the reception of a number of carnivorous reptiles of the triassic period. The dentition is of the carnivorous type, there being three distinct sets of teeth, incisors, canines, and molars. The canines were long and pointed. In *cynodraco*, which is regarded as the typical genus, the canines are not only immense, but are compressed, and have the hinder trenchant border minutely serrated, as in the canines of the saber-toothed tiger or machærodus (q.v.). The humerus also resembles in some respects that of the cat family, and other carnivorous mammals, in having a supra-condyloid foramen for the protection of the median nerve and brachial artery.

Class IV., Aves.—See Birds. The members of this class may be defined as *oviparous vertebrates* with warm blood, a double circulation, and a covering of feathers (Owen). The embryo has an amnion and allantois, and branchiæ are never developed at any period of existence upon the visceral arches. The skull articulates with the vertebral column by a single occipital condyle. The form of the vertebral centra varies, but it is never amphicœlous or cup-shaped at both ends, except in the remarkable *ichthyornis dispar*, found by Prof. Marsh in the cretaceous rocks of North America. Each half of the ramus of the lower jaw consists of a number of pieces which are separate in the embryo, and the jaw articulates with the skull, not directly, but by the intervention of a *quadrate bone*, as in reptiles. This peculiarity, together with that of the possession of nucleated red blood globules, has led Prof. Huxley, notwithstanding vast differences in other respects, to place birds and reptiles in one division, to which he has given the name of *sauropsida* (q.v.). The heart, in birds, contains four chambers, two auricles and two ventricles, as in mammalia, and there is no communication between the pulmonary and systemic circulation, as in reptiles. The blood is warm

(103° to 104° Fahr.). The respiratory organs are in the form of spongy, cellular lungs, which are not freely suspended in pleural sacs, and the bronchi open into a number of air-sacs in different parts of the body. The respiration in birds is more complete and active than in any other class of vertebrates, which accounts for their higher temperature, and is naturally associated with their great activity and high order of *physique*. The following arrangement, somewhat altered from Cuvier's classification, is the one probably most generally followed. It includes seven orders: 1. Natatores, or swimmers; 2. Grallatores, or waders; 3. Cursores, or runners; 4. Rasores, or gallinaceous birds; 5. Scansores, or climbers; 6. Insessores, or perchers; 7. Raptores, or birds of prey. To these may be added two subclasses, saurornithes, containing the order *saururæ;* and odontornithes, containing two orders, *odontolcæ* and *odontornæ*.

Order 1, *Natatores*, divided into four families, viz., 1, *Brevipennatæ*, including the penguins (q.v.), auks (q.v.), guillemots (q.v.), divers (q.v.), and grebes (q.v.); 2 *Longipennatæ*, comprising laridæ (q.v.) and procellaridæ (petrels); 3, *Totipalmatæ*, including the pelicans (q.v.), cormorants (q.v.), gannets (q.v.), frigate bird (q.v.), darter (q.v.), and others; 4, *Lamellirostres* (q.v.), including the ducks (anatidæ), geese (anserinæ), swans (cygnidæ), and others. See Albatross, Anas, Brent-goose, Black-duck, Blue-wing, Canvas-back, Cereopsis, Garrot, Goose, Hareld, Kittiwake, Harlequin-duck, Musk-duck, Palamedidæ, Scaup-duck, Shell-drake, Shoveler, Summer-duck, or Wood-duck, Swan, Spheniscidæ, Teal, Tropic Bird.

Order 2, *Grallatores.*—See Grallæ, including the families *otidæ* or bustards (q.v.), *charadriadæ* (q.v.), or plovers (q.v.). See also Kildeer and Lapwing. *Gruidæ* or cranes (q.v.). See also Demoiselle. *Ardeidæ*. See Heron, Adjutant, Ibis, Marabou Stork, Night heron, Open-bill, Sand-hill Crane, Spoonbill Stork, Tantalus. *Scolopacidæ* (q.v.). See Avocet, Curlew, Godwit, Greenshank, Ruff, Snipe, Woodcock, Yellow-legs. *Rallidæ* (q.v.) or rail (q.v.). See also Gallinule, Ganga or Sand-grouse, and Notornis.

Order 3, *Cursores*, divided into two families, *struthionidæ* and *apterygidæ*. See Cassowary, Emu, Dinornis, Dodo, Ostrich, Nandu, and Apteryx.

Order 4, *Rasores*, or gallinaceous birds (q.v.), including the following families: *Columbidæ* (q.v.). See also Bronze-wing, Carrier-pigeon, Dove, Fruit-pigeon, Ground-dove and Ground-pigeon, Partridge-pigeon, Pigeon, and Turtle-dove. *Cracidæ*. See Curassow and Guan. *Phasianidæ* (q.v.). See also Argus, Fowl, Guinea-fowl, Lyre-bird, Pheasant, Macartney-cock, Turkey. *Tetraonidæ*, or grouse family. See Black-cock, Bonasia, Capercailzie, Francolin, Grouse, Partridge, Ptarmigan, Quail, Virginian Quail. *Chironidæ*. See Sheath-bill. *Tinamidæ*. See Tinamidæ.

Order 5, *Scansores* or climbers (q.v.), containing the following families: *Psittacidæ* or parrots (q.v.). See also Cockatoo, Lorikeet, Macaw, Paroquet, and Owl-parrot. *Ramphastidæ*. See Toucan. *Picidæ*, or woodpeckers (q.v.). See also Barbet and Wryneck. *Cuculidæ*. See Cuckoo and Honey-guide.

Order 6, *Insessores* (q.v.), divided into four sections or tribes, according to the form of the beak, viz., *conirostres*, *dentirostres*, *tenuirostres*, and *fissirostres*.

The conirostres contain the following families: *Fringillidæ* (q.v.), or finches (q.v.). See Beef-eater, Bullfinch, Bob-o-link, Crossbill, Goldfinch, Greenfinch, Hawfinch, Linnet, Ortolan, Pine-finch, Snow-bird, Snow-bunting, Weaver-bird, and Yellow-bird. *Corvidæ*, or crows. See Corvidæ, Crow, Magpie, Rook, Umbrella-bird. *Sturnidæ*, or starlings (q.v.). See also Bower-bird, Grakle, and Troopial. *Paradisidæ* (q.v.) or bird of paradise (q.v.). *Buceridæ*. See Hornbill (sometimes placed with corvidæ). The dentirostres contain the following families: *Sylviadæ* (q.v.), or warblers (q.v.). See also Beccafico, Beccamoschino, Black-cap, Golden-crested Wren, Hedge-sparrow, Nightingale, Tit, Tailor-bird, White-throat. *Muscicapidæ* (*colopteridæ*) or fly-catcher family. See King-bird, Fly-catcher, and Insectivorous Birds. *Lanidæ*, or shrikes (q.v.). See also Baritah, Vireo or Greenlet, and Woodchat. *Turdidæ* or *Merulidæ* (q.v.), or thrushes (q.v.). See also Ant-catcher, Banana-bird, Blackbird, Bluebird, Blue-throat, Dippér, Redbreast, Red-wing, Ring-ouzel, Robin, and Thrasher. The tenuirostres contain the families: *Ampellidæ* or chatterers (q.v.). See Bell-bird, Cotinga, and Wood-swallow. *Upupidæ*. See Hoopoe and Rifle-bird. *Trochilidæ*. See Humming-bird. The fissirostres contain several families whose classification is not well settled. See Bee-eater, Goat-sucker, Night-hawk, Whip-poor-will, Swallow, Swift, Pewee.

Order 7, *Raptores.*—The members of this order are distinguished by their strong, curved, sharp-edged, and sharp-pointed bills, the upper mandible being the longest, and hooked at the tip. The order is divided into two great sections: *nocturnal raptores* and *diurnal raptores*, the first comprising the single family *strigidæ* (q.v.), or owls (q.v.); the second, or diurnals, including two subsections or groups, *accipitrinæ*, comprising the falcons, hawks, and eagles, and the *vulturidæ*, or vultures. The raptores always live in pairs and the males and females are said to live together during life, instead of mating every season, like other birds. The female is generally larger than the male, but has less brilliant plumage. See Condor, Eagle, Eagle-hawk, Eagle-owl, Erne, Elanet, Goshawk, Falcon, Harrier, Hawk, Honey-buzzard, Lam-

MERGEIER, OSPREY, OWL, PIGEON-HAWK, PEREGRINE FALCON, SPARROW-HAWK, and VULTURE. The subclass saurornithes contains the order *saururæ*, which includes only the extinct bird *archæopterix macrura*, a single specimen of which has been discovered in the lithographic slates of Solenhofen, in the upper oolite. It was about the size of a rook, and had the remarkable peculiarities of two free claws on each wing, and a lizard-like tail, longer than the body, composed of separate vertebræ. The tail was destitute of a plowshare bone, and each vetebra supported a single pair of quills. The metacarpal bones were also not anchylosed together as in all other birds. The subclass odontornithes contains two orders, *odontolcæ* and *odontornæ*. See ODONTORNITHES.

CLASS V. MAMMALIA (q.v.).—This class comprises fourteen well-recognized orders, as follows :

1, *Monotremata* (q.v.).—See DUCK-BILL and ECHIDNA.

2, *Marsupialia* (q.v.).—See BANDICOOT, FLYING PHALANGER, KANGAROO, OPOSSUM, PHALANGER, PHASCOGALE, and YAPOCK.

3, *Edentata* (q.v.).—See AARD-VARK, ANT-EATER, ARMADILLO, GLYPTODON, MEGATHERIUM, MYLODON, SLOTH, WART-HOG.

4, *Sirenia* (q.v.).

5, *Cetacea* (q.v.).—See BELUGA, DELPHINAPTERA, DELPHINORHYNCHUS, DOLPHIN, GRAMPUS, KILLER, WHALE.

6, *Ungulata* (q.v.).—See ALPACA, AXIS, CAMEL, CAPRIDÆ, CASHMERE GOAT, BABYROUSSA, BOAR, BUSH ANTELOPE, BOUQUETIN, DZIGGETHAI, EQUIDÆ, HORSE, BARB, PONY, RACE-HORSE, QUAGGA, ASS, ZEBRA, BOVIDÆ, BUFFALO, GNU, ZEBU, MUSK-OX, OX, NIARE, SHEEP, GOAT, CARIACOU, DEER, ANTELOPE, ELAND, ELK, GAZELLE, HART, ROE, MUSK, REINDEER, MEGACEROS HIBERNICUS, KAAMA, IBEX, NYLGHAU, OREODONTIDÆ, PACHYDERMATA, STAG, TITANOTHERIUM, PALEOTHERIUM, TOXODONTIA, GAUR, HIPPOPOTAMUS, LOPHIODON, TAPIR, ZAMOUSE.

7, *Hydracoidea*.—See DAMAN.

8, *Proboscidia*.—See ELEPHANT, LOXODON, MASTODON, and DINOTHERIUM.

9, *Carnivora*.—Distinguished by always having two sets of teeth, which are simply covered with enamel, and are always of three kinds : incisors, canines, and molars. The clavicles are either altogether wanting, or are rudimentary. The order is divided into three sections : pinnigrada, plantigrada, and digitigrada. *Sec.* 1. *Pinnigrada*, comprises the amphibious seals and walruses. See PINNIGRADES, MORSE, OTARY, and SEAL. *Sec.* 2. *Plantigrada* (q.v.). See BADGER, BEAR, COATI, GLUTTON, and RACCOON. *Sec.* 3. *Digitigrada*, in which the heel is raised above the ground, so that the animals walk more or less upon the tips of the toes, but this characteristic varies. We will divide this section into five families : *Fam.* 1. *Mustelidæ* (q.v.). See ERMINE, FERRET, MARTEN, MINK, OTTER, POLE-CAT, and SKUNK. *Fam.* 2. *Viverridæ* (q.v.). See also ICHNEUMON, SURICATE, CIVET, and GENET. *Fam.* 3. *Hyænidæ*. See HYÆNA and AARD WOLF. *Fam.* 4. *Canidæ*, comprising the dogs, wolves, foxes, and jackals. See BEAGLE, BEDLINGTON TERRIER, BULLDOG, BLOODHOUND, CARRIAGE-DOG, COCKER, CERDOCYON, CORSAC, DHOLE, DOG, DOG-FOX, DUSICYON, FENNEC or ZERDA, FOX, FOXHOUND, GREYHOUND, HARRIER, HOUND, JACKAL, LAP-DOG, LURCHER, MALTESE DOG, MASTIFF, NEWFOUNDLAND DOG, NOOTKA DOG, POODLE, PUG, POINTER, SETTER, SHEPHERD'S DOG, WOLF, WOLF-DOG. *Fam.* 5. *Felidæ* (q.v.). See CAT, JAGUAR, TIGER, TIGER-CAT, OCELOT, PUMA, MACHÆRODUS.

VER'TIGO, in medicine, designates a sensation which the patient describes as one of going to fall, or of turning round, or of everything turning round him. It comes on without premonitory symptoms, excepting a sense of disturbed balance, which may either precede, accompany, or follow it. Associated with it are frequently some of the following symptoms : flashes of light before the eyes, buzzing in the ears, painful sensations in the head, nausea, vomiting, trembling with cold perspirations, muscular tremors, a full, slow, or small and frequent pulse, flushing or pallor of the face, and cold feet.

Giddiness and *dizziness* are only other names for vertigo, although giddiness is com-

monly applied to its milder forms. Attacks of it come on in paroxysms, usually repeated several times a day, and lasting from a few minutes to a quarter of an hour. This disease is frequently chronic, the chief predisposition to it being in middle and advanced age. Childhood is nearly exempt from it, an observation in accordance with the well-known fact, that children can bear rapid rotatory movements without the induction of giddiness better than adults. A plethoric constitution, especially if associated with a sedentary mode of life, the so-called change of life in women, the debility brought on by exhausting discharges, and the abuse of spirituous liquors, may be regarded as predisposing causes to this affection. The direct cause of vertigo is doubtless an irregularity of the supply of blood to the brain. Hence any condition that occasions either an increase or diminution in the supply of blood, is followed by vertigo. For example, it commonly accompanies disease of the heart, and especially hypertrophy of the left ventricle; it is also induced by suppressed hemorrhoids, or other constant form of discharge or loss of blood. Injuries and diseases of the brain, and especially of the cerebellum, are often accompanied by this symptom, and so also are diseases of the spleen. Among the most common exciting causes are intoxication, not only from alcoholic drinks, but from narcotics, such as smoking tobacco, inhaling carbonic acid gas, or semi-poisoning by belladonna, digitalis, hyoscyamus, etc., gorging the stomach with indigestible food (especially if highly carbonated drinks are at the same time taken); unusual movements or positions of the body, and especially of the head, as in sea-voyages, continued stooping, etc.

There is a peculiar kind of vertigo which occurs in dreams. The direction of the apparent movement is generally from above downward; dreams of tumbling down stairs being, according to Romberg, the most common; people also dream of sinking into the earth, of chasms opening before them, etc.

According to Boerhaave, "vertigo is the most easily cured of all the diseases of the head." This statement is too positive; the vertigo that is caused by profuse discharges and exhaustion is curable, while it is beyond the aid of treatment when it accompanies cerebral disorganization. The *treatment* of course depends upon the cause; while in some cases tonics (the mineral acids, small doses of nux vomica, quassia, etc.) are required; in others, the local abstraction of blood from the nape of the neck, cold effusion, etc., are required. The following rules are, however, generally applicable for the treatment of patients subject to giddiness. They should avoid violent, continuous, or rotatory exercise, abstain from highly nutritious or heating articles of diet, and from suppers; they should not indulge in much sleep, or the use of feather-beds or of warm baths. Counter-irritation to the skin by sinapisms, foot-baths with mustard, the use of the flesh-brush, with cold washing of the body, and the administration of cooling laxatives are to be recommended. (A good laxitive of this kind is obtained by mixing six drams of sulphate of magnesia [Epsom salts] with two drams of carbonate of magnesia, and taking a teaspoonful three times a day.) When the patient feels the attack coming on, Romberg directs that he should "direct his full attention to movement. The patients do this, in a measure, of their own accord, by supporting themselves firmly with their hands and feet, in order to resist the illusory movement. The sense of vision may be employed for the same purpose; thus, the vertigo produced by rotatory movement of the body may be suppressed by looking steadily at the finger held up to the eye, or by turning round in a direction opposite to the previous movement."—*On Diseases of the Nervous System*, Syd. Soc. Ed. vol. i., p. 102.

Few of our readers are probably aware of the remarkable vertiginous conditions which they can artificially induce in their own persons. Purkinje, the well-known anatomist and physiologist, was the first who brought these remarkable facts within the range of experimental science in two memoirs published in 1820 and 1827. Vertical vertigo is thus produced. The experimenter—who must be standing—has a somewhat heavy weight attached to each hand, and as he carefully watches the sensation produced by gravitation for some time, he feels the weights growing heavier and heavier, till he can no longer bear them. On putting them down, when he feels he can bear them no longer, it appears to him as if he was impelled to mount straight upward, and as if the arms were shortened, and the hands must creep up to the thorax. Similar experiments with the muscles of the eye afford still more striking results. "If the face," says Purkinje, "be turned to the ceiling, and the eye be fixed on a given point, round which, as the pole of a vertical axis, the body is turned a certain number of times, the visible objects of the ceiling, as well as the floor of the room, will, if the position of the head and the direction of the eyes be maintained, appear to move in a horizontal direction. If, during the proceeding, the head be brought back into the ordinary upright position, the horizontal will be turned into vertical vertigo; and this sensation will be communicated to the tactile sense of the hands and feet, the floor appearing to sink down on one side, and to rise on the other."—See Rust's *Magazine*, etc., 1827, vol. xxiii. p. 290.

An analogous effect is produced by standing on the brink of, or in, a running stream, and fixing the eyes on the water; after a time, the sensation begins all at once of being borne along against the current. When this sensation comes on in wading in a river, it is very difficult to keep one's feet; and hence it is dangerous to let the eyes rest on the current close by.

Hitherto, we have spoken of vertigo, merely as a sensation; but there are certain

morbid conditions of the brain, and certain operations which experimental physiologists can perform upon it, that will give rise to what may be termed *vertiginous movements*, if we include under the term vertigo *straight* as well as circular movements, as is usually done by writers on this subject. From the experiments of Magendie and Flourens, which have been confirmed by Krauss and Hertwig, it follows that: 1. Removal of both corpora striata of the brain induces an irresistible tendency to advance, the animal shooting straight forward like an arrow; 2. Slicing the cerebellum, whether horizontally or vertically, causes the animal to walk backward; 3. Section of the corpora quadrigemina of one side, and of one side of the pons varolii, excites rotatory movements and gyrations of the animal toward the injured side; while division of the corresponding parts on the opposite side restores the balance. Vertiginous movements consequent on disease were described by the veterinary surgeons in sheep before they were noticed in the human subject. The *cœnurus cerebralis*, which is now known to be the larva of a species of tapeworm (*tænia cœnurus*) infesting the dog, is the well-known hydatid in the brain of sheep, producing in that animal the disease known under the various names of staggers, turn-sick, goggles, rotatory disease, etc. How this hydatid excites these movements when it destroys certain parts of the brain, is now explained by the experiments previously noticed. Dr. Romberg has collected a number of very interesting cases of vertiginous movements in the human subject.—On this subject, in addition to Romberg's work, the reader may consult a paper by Dr. Paget, "On Morbid Rhythmical Movements," in the *Edin. Med. and Surg. Jour.* (1847).

VERTIN, John, d.d., b. Carniola, Austria, 1844. He graduated at St. Francis sem. (Rom. Cath.), Milwaukee ; served as a missionary in n. Wisconsin, and in 1879 was consecrated bp. of Marquette.

VERTNER, Rosa (Griffith), now Mrs. Jeffrey, b. Miss., in 1828; educated at bishop Smith's seminary, Lexington, Ky., in which place she has spent most of her life. She has written many poems, collections of which were published in 1857, 1871, and 1881. She has also written the novels *Woodburn* (1864), and *Marsh* (1884), and many tales and sketches.

VERTUE, George, distinguished as an English engraver and antiquary, was born in London in the year 1684, of poor but respectable parents. At the age of 13; he was set to study under an eminent French engraver there; subsequently, he became a pupil of Michael Vandergucht, with whom he remained seven years, and in 1709, he commenced business for himself. He was generously befriended by sir Godfrey Kneller, the great portrait-painter of the day, who did much to procure him employment. His talent soon made itself recognized; and his eminent success in an engraved portrait of archbishop Tillotson, for which he received a commission from lord Somers, at once placed him in the very front rank of his profession. In 1711, on the institution of the academy of painting, with his friend sir Godfrey Kneller as president, he enrolled himself as a member: but his contributions were few and unimportant. In his own more special department, he wrought through life assiduously, confining himself for the most part to reproductions of the portraits of Kneller, Richardson, and one or two others of the more eminent painters of the day. On the accession of George I., he issued a large engraved head of that monarch, which had an immense run, much increasing his reputation with the public. Himself, from an early period, devoted to antiquarian research, which from time to time he prosecuted in journeys hither and thither throughout England, he was appointed, in 1717, engraver to the society of antiquaries, in which capacity he worked up to the time of his death, which occurred on July 24, 1756. He lies buried in the cloisters of Westminster abbey. In addition to his eminence in his art, he was a man of considerable general accomplishment; an adept in drawing and music, and with a competent knowledge of the French, Dutch, and Italian languages. He projected a *History of the Arts in England*, and had accummulated masses of material for it. At his death, his manuscripts were bought by Walpole, who made free use of them in his *Anecdotes of Painting in England*. In a supplementary volume of that work, entitled *A Catalogue of Engravers who have been born or resided in England*, a full list of his works is given, with some interesting notices of his character, the genuine unassuming worth of which is indicated in an unaffected expression of respect, of rather more than usual significance, as coming from the caustic and supercilious Walpole.

VERTUMNUS. See Pomona.

VERULAM. See Bacon, Francis.

VERVAIN (*Verbena*), a genus of plants of the natural order *verbenaceæ*, with a 5-cleft calyx, one division a little shorter than the rest, the limb of the corolla irregularly 5-lobed, the stamens (4 or 2) included within the corolla, the fruit a 4-seeded utricle, which soon breaks, so that the ripe fruit consists of four adherent achœnia. The species are herbaceous plants and small shrubs, with undivided. trifid, or multifid leaves, natives chiefly of the warmer temperate parts of the world. The common V. (*V. officinalis*) a perennial plant, with erect somewhat hispid stem, rough lanceolate inciso-serrate or trifid and laciniate leaves, and filiform spikes of pale lilac flowers, is a native of America and of most of the temperate countries of the world. It is a common ornament of flower-borders, continuing to blossom all summer. It had at one time a very high reputation as a medicinal plant, but its virtues are now regarded as imaginary. It has also been connected with some of the superstitious rites of different nations, as of the

Greeks and Romans, the ancient Persians, and the British Druids.—A number of species of vervain, chiefly American and East Indian, are occasionally cultivated for the beauty of their flowers.

VERVELS, or VARVELS, small rings attached to the ends of the jesses of a hawk through which the leash is passed that fastens the hawk to its block. They occur as a heraldic charge.

VERVICK, or WERVICQ, t. of Belgium, in the province of West Flanders, on the Lys, 8 m. s.e. of Ypres. It has important tobacco manufactories. Pop. '90, 7484.

VERVIERS, a prosperous manufacturing town of Belgium, in the province of Liège, most picturesquely situated on the river Vesdre, 15 m. e.s.e. of Liège on the Brussels and Cologne railway. It is of recent growth; and being composed wholly of workshops and of the dwellings of the manufacturers and their workmen, there are no remarkable objects of attraction. Verviers is the great center of the second-rate cloth manufactures in Belgium. Great quantities of cloth are exported, and the goods which are chiefly coarse woolens, are said to be better and cheaper than those of either France or England. Brewing, tanning, and dyeing are also important industries. The waters of the Vesdre possess qualities which render them admirably fitted for dyeing. Pop. '91, 48,907, and including the annexed suburbs, Dison, Ensival and Hodimont, 73,695.

VERY, JONES, 1813–80, b. Mass.; graduated at Harvard college in 1836 and was Greek tutor there for two years. Besides frequent contributions to periodical literature, he published *Essays and Poems* (1839). As a writer of sonnets he is thought by many to have been unsurpassed in this country, and his critical writings, though like his poems, few in number, show learning and insight.

VESALIUS, ANDREW, the celebrated anatomist, was a native of Brussels, where he was born in 1514. He studied classics at Louvain, and anatomy and medicine first at Cologne, then at Montpellier, and finally at Paris, where his preceptors were Gunther, Sylvius, and Fernelius. So keen was his love of dissection that, in order to procure subjects (at that time no easy matter), he ran considerable risks at the hands of the municipal authorities. Driven from Paris by the outbreak of war between Francis I. and Charles V., he returned to the Low Countries, where he served as physician and surgeon in the imperial army from 1535 to 1537. In 1540 he went by invitation to Pavia, where he taught anatomy till 1544. He afterwards gave public lectures on this subject at Padua, Bologna, and Pisa. Finally he was made physician-in-chief to Charles V. at Madrid, where he continued mainly to reside. He was now at the zenith of his prosperity, when an accident befell him which brought his career to a premature and disastrous close. A Spanish gentleman died in 1564, and permission to dissect the body was granted by his relatives to Vesalius. Life, however, was ascertained to be not quite extinct when Vesalius began the operation, the heart being found still palpitating. The family of the deceased, with inconsiderate vindictiveness, arraigned Vesalius before the inquisition, by which tribunal some terrible sentence would have been passed upon him, but for the interposition of Philip II., who procured for the unfortunate anatomist the milder penalty of an injunction to make a pilgrimage to the Holy Land. Vesalius, accordingly, in the train of the Venetian general Malateste, proceeded to Cyprus, and thence to Jerusalem. While sojourning in that city, he was invited to occupy the chair of anatomy, just vacated in Padua by Fallopius. It is supposed that, in compliance with this invitation, he embarked for Europe; but the ship in which he sailed was wrecked on the shore of Zante. Hunger and misery of mind proved too much for him, and he died in a village of that island in 1564.

Vesalius was one of those men of science who contributed to disenthral the minds of his contemporaries from their servile belief in the ancients. Galen was then to anatomy what Aristotle was to logical method; and Vesalius assailed his authority by independent researches into nature. His first great publication was a series of anatomical tables entitled *Suorum Librorum de Corporis Humani Anatome Epitome* (Basel, 1542, fol.). The plates, from drawings by the best masters, and engraved on wood, were nearly all re-incorporated in his great work *De Corporis Humani Fabrica Libri Septem* (Basel, 1543). Great value is placed on the earliest impressions of these plates, the explanations of which, however, were revised by Vesalius in his second (Basel) edition in 1555. He published in 1546 his severe attack on the errors of Galen's anatomy, the well-known *De Radicis Chinæ usu Epistola.* The cause of Galen was then espoused by Galen's disciple Fallopius, to whom Vesalius replied in his trenchant *Anatomicarum Gabrielis Fallopii Observationum Examen* (1561). After his death, a work entitled *Chirurgia Magna*, published under his name, but really a compilation from the ancient anatomists, was edited by his disciple Borgarucci. The great edition of Vesalius's works appeared with fine plates at Leyden in 1725, under the superintendence of Boerhaave and Albinus. See the lives by Burggraeve (1841), Mersman (1845), Meynants (1846), and Roth (1892).

VESICANTS, or BLISTERING AGENTS, are substances which, if kept in contact for some time with the surface of the body, excite such irritation as to cause the effusion of serum from the true skin, leading to the separation and elevation of the cuticle, and the formation of a vesicle or blister. They are employed in the practice of medicine for the

purpose of relieving or removing the diseased condition of some internal part, by producing a determination of blood from the interior to the surface over the seat of the affection. They likewise are of great value from their action as general stimulants to the system, and as such are often used with great benefit in the advanced stages of low continued fever. Moreover, they are not unfrequently employed for the direct purpose of withdrawing serum from the vascular system, and with this view they are prescribed with advantage in cases of sudden effusion into the pericardium or the pleura. Blisters used with this object should be of large size, and should be kept in contact with the skin sufficiently long to produce their full effect (24 hours being in some persons necessary for that purpose). Lastly, vesicants are occasionally applied to the surface of the body, for the purpose of removing the cuticle, so as to permit the direct application of various medical agents (especially mercury and morphia) to the absorbing surface of the true skin. It must be recollected that in infancy and childhood, owing to the extreme readiness with which inflammation of the skin is then set up, these agents must be used with extreme caution.

To produce vesication, *cantharidine*—the active principle of *cantharides*, or Spanish flies—in one of its various forms is generally employed, although other substances, afterward to be noticed, are occassionally used. Cantharidine is a white crystalline substance, which is extracted from the powdered insects by rectified spirit, and whose composition is represented by the formula $C_{10}H_6O_4$. It is a very active poison, and produces immediate inflammation of the skin whenever it comes in contact with it, is very volatile, even at ordinary temperatures, and is soluble not only in alcohol, but in chloroform, ether, strong acetic acid, and many oils. This substance is employed in the form of plaster (*emplastrum cantharidis* of the *Pharm. Brit.*), blistering fluid (of which there are several excellent forms, such as *acetum canth.*, *æther canth.*, and *collodion canth.*, none of which are in the *Pharm. Brit.*), and blistering tissue (of which there are several forms, known as *tela vesicatoria, charta ves., blistering cloth,** etc., none of which are officinal). Although the fluids and tissues are the cleaner and neater preparations, the old-fashioned *cantharides plaster* is far the most commonly employed in general practice, and is, by many of the authorities in the profession (among whom we may name the late Prof. Syme of Edinburgh, and Prof. Lister, now of London), considered as the most efficacious (its superiority being due to its slower and more prolonged action). In prescribing a blister, it is expedient to sketch the size and shape desired. Before applying it, the skin should be well washed with warm water. If the patient's skin is not easily acted upon, the part should be sponged with vinegar; while if it is very susceptible, and he is liable to strangury from the application of blisters, a piece of tissue-paper should be placed between the skin and the plaster. (In speaking of the plaster, which is a solid mass, we assume that it is spread on some fitting material, as wash-leather, soft brown paper, etc., the popular idea of a plaster always including the material on which it is spread.) In order to insure close contact with the skin, the blister should be gently warmed, carefully applied, so as to avoid creases, and kept in its place by a bandage. To produce their full action, blisters should remain from ten to twelve hours, and if on their removal after that time full vesication has not been produced, a hot bread-and-water poultice will often produce the desired effect. The raised cuticle should be punctured, to allow of the escape of the serum (except in the case of children and persons of very irritable skin, when the vesications should be left unopened), and a dressing of simple ointment or spermaceti ointment on soft rag applied, and repeated in twenty-four hours afterward; or the part may be at once covered with cotton-wool, which until it gives off a bad smell, can remain till the skin is healed. The troublesome *itching* which often follows the application of a blister, is best relieved by the application of a bread-and-water poultice, moistened with the dilute solution of acetate of lead, formerly known as Goulard's *vegeto-mineral water*. Dr. Neligan, in his highly practical work *On Medicines*, speaks so strongly of *collodium vesicans* as a blistering agent, that although we have no personal experience of it, we shall, on his authority, briefly notice it. It is prepared, when required, by mixing together equal parts of collodium and cantharidal ether (obtained by digesting for three days one part of coarsely powdered cantharides in two parts of sulphuric ether, and expressing). It possesses the advantage that its strength can be readily increased or diminished. "It is now much used for blistering," he observes "owing to its cleanliness, its certainty, and the facility with which it may be applied in the neighborhood of joints, or to other parts which are difficult to blister by the ordinary method. It is applied with a camel-hair pencil; two scruples are sufficient to blister a surface as large as the palm of the hand. It is preferable to apply the quantity to be used twice, instead of at one time, on the place to be blistered."

When a blistering agent with very rapid action is required, as in the state of collapse in cholera, recourse may be had to the application of boiling or nearly boiling water† to

* We have not included the well-known *papier d'Albespeyres*, which is often sold for this purpose, because it is not sufficiently powerful. It is useful for keeping open an already blistered surface.

† Strange and paradoxical as it may appear, "in the absence of other more suitable means, *cold water* may be used as efficiently as boiling water, and will not present so formidable an appearance to the patient. A piece of bibulous paper (common blotting-paper, for example) should be soaked in cold water, applied to the part to be vesicated, and covered with three or four folds of dry paper. A common smoothing-iron heated to 212° should now be pressed three or four times over all, and on removing the paper, the part will be found vesicated."—Neligan, *op. cit.*, p. 325.

a portion of the abdomen, the surrounding surface being protected by a wall of damp cloths; or in less urgent cases, as retrocedent gout showing itself internally, an almost immediate blister may be produced by saturating a piece of lint of the size of the desired blister in the strong solution of ammonia, and applying it to the skin with moderate pressure. By the time that the ammonia has evaporated, the required result is usually obtained. When it is desired to keep up a discharge from a blistered surface (instead of healing it, as is most commonly required), or to produce a *perpetual blister*, we dress the raw surface with irritants of various kinds, such as savine ointment, *papier d'Albespeyres*, etc. At each fresh dressing, which in summer should take place twice a day, the part should be cleansed with warm water.

VESICA PISCIS (barbarous Lat. bladder fish, bladder evolved out of a fish), a term often, but not very correctly, used for the aureole or glory, of a pointed oval shape, formed by the intersection of two circles, which, in the religious symbolism of the early middle ages, is often represented encircling the whole body of the Saviour. This form is supposed to have been gradually evolved out of the figure of the fish, which is prominent in the symbolism of the early Christians on sarcophagi and elsewhere, and whose use arose out of an anagram on the initial letters of *Ιησοῦς Χριστὸς Θεοῦ Υἱὸς Σωτήρ*, Jesus Christ, son of God the Saviour. The ovoidal form, generally designated by English antiquaries the Vesica Piscis, is much used in painted glass, and became from the 12th c., the almost invariable form of the seals of ecclesiastical persons and institutions.

VESOUL, a small t. in the e. of France, capital of the dep. of Haute-Saône, stands in a fertile and picturesque country, overlooked by the mountain called the Motte-de-Vesoul, at the confluence of the Columbine with the Durgeon, 236 m. e.s.e. of Paris. The manufactures of the town are unimportant, but the environs are as fertile as they are beautiful. A trade in grain, hay, hides, and wine is carried on. Vesoul is the birthplace of the artist Gérôme. Pop. (commune), '91, 9770.

VESPASIA'NUS, Titus Flavius, Roman emperor, was a native of Reate, in the Sabine country, of humble origin. After serving with distinction in various military grades in Thrace, Britain, and Africa, he was sent by Nero to conduct the Jewish war. This appointment he owed to his recognized merits, for he was not a favorite with the emperor, whom he had offended by falling asleep during the recitation of one of his poetical compositions. He conducted the war with vigor, reduced Judæa, and finally laid siege to Jerusalem. At this time occurred the struggle for the imperial dignity between Otho and Vitellius, after the murder of Galba. The legions serving in the east were indignant that the empire should be disposed of at the will of the prætorian guards. Their own gen. was proclaimed emperor, and quickly acknowledged as such by all the east, and, after the death of Vitellius, by Italy and all the provinces. Leaving his son Titus to prosecute the siege of Jerusalem, he repaired to Rome, where he was joyfully received, and immediately set about the work of restoring order. He kept his soldiers under firm discipline, improved the finances, co-operated cordially with the senate in the administration, and did much by his example to lessen the ill effects of the prodigality and luxury of his predecessors. An interesting biography of him has been written by Suetonius, and from the personal anecdotes there recorded, we are enabled to estimate clearly the character of the man. He was simple and unostentatious in his mode of life, too shrewd to listen to flattery, liked a joke, was good humored, and easy of access. He is charged with being avaricious, and at times he certainly sought to obtain money by rather undignified ways; but though niggardly in personal expenditure, he was lavish in embellishing the city with public works, and a munificent patron of the arts and sciences. He is chargeable also with one or two acts of cruelty, but usually he bore provocation with great good temper. He died 79 A.D., in the 69th year of his age, after a reign of 10 years.

VESPERS (Lat. *vespere*, in the evening), one of the canonical hours of the breviary, called also anciently *lucernarium*, from *lucerna*, a lamp. It is a service of very ancient use, being plainly referred to in the apostolical constitutions, and is noticeable as that one among the canonical hours which in the Roman Catholic church continues to be regularly sung as one of the ordinary public services of parish churches, no less than in cathedrals where the entire of the hours are chanted. It resembles lauds, and consists of five psalms and antiphons, a lesson, a hymn with versicle and response, a canticle (the magnificat), and a collect or prayer. The psalms sung at vespers are Ps. cix.–cxlvii., which are distributed over the several days of the week. The service of vespers has given occasion to some of the most brilliant efforts of modern musical composers. The evening prayer of the English prayer-book corresponds partly with the vespers, partly with the compline (*completorium*) of the Roman breviary.

VESPERTILIONIDÆ, one of the four families of the insectivorous section of bats, comprising the ordinary bats of the old and new world, and distinguished by having a dentition much like that of other insectivorous mammals, the molar teeth being furnished with cusps adapted for crushing insects, and the incisors small. The nose has no leaf-like appendages. The tail is elongated and inclosed in a large membrane extending between the thighs. The family has a wide range, embracing most of the species of northern temperate countries. It has been divided into about 20 genera, by far the most extensive of which is *vespertilio*. See Bat and Noctilionidæ.

VESPUCCI, Amerigo. See Amerigo Vespucci.

VEST, George Graham, b. Frankfort, Ky., 1830; graduated at Centre coll., Ky., 1848, and at the law dept. of Transylvania univ., 1853; removed to Mo. to practice; was in the state legislature, 1860-61. He was a member of the Confederate congress for three years; was elected, as a dem., to the U. S. senate in 1879, 1885, 1890, and 1897.

VES'TA—VES'TALS. Vesta, an ancient Latin divinity, whose worship was the embodiment of an idea deeply rooted in the Latin, and particularly in the Roman mind—viz., that the state was one great family. As the Lares were the tutelary guardians of the individual household, so the Penates and Vesta watched over the welfare of the state. The Greek *hestia* (hearth) is a kindred conception; and if the word is the same, it may be conjectured that the worship of the chaste divinity that presided over domestic life goes back to a period when the Greeks and Latins were still an undivided people. The state, we have said, was regarded by the Latins as one great family, so each community had its public altar to Vesta, the central one for the whole Latin people being at Lanuvium, about 20 m. from Rome, on the Appian way, where the Roman consuls and other officers offered sacrifices on entering upon their offices. The common hearth of the Greeks was at Delphi. There was also a temple of Vesta at Rome, which stood in the forum, near the temple of the Penates (see Lares, etc.), between the Palatine and Capitoline hills; it was open during the day, and closed during the night. On the first of March each year, the sacred fire was renewed; on June 9, the *vestalia* were held in honor of the goddess; and on the 15th of that month, the temple was cleared out, and the dirt carried into a narrow lane (*angiportus*) behind the temple, which was locked by a gate, that none might enter. See illus., Mythology, vol. X., fig. 7.

The goddess herself was a virgin, and her fire was carefully tended night and day by the *Vestal* virgins. The number of these priestesses was originally four, but two were subsequently added, increasing the number to six. At first, they were chosen by the kings; but after their expulsion, by the pontifex maximus, who, when a vacancy had to be filled up, selected twenty damsels between the ages of six and ten years, from among whom one was chosen by lot. A father could offer his daughter for the office, if he chose, but this seldom happened. The necessary qualifications for the office of Vestal were, that the maiden should be the daughter of free-born parents, then alive and resident in Italy, and engaged in no dishonorable occupation; that she herself should not be younger than six, nor older than ten years, and free from any physical defect. The period during which the priestess was bound to the service of Vesta was thirty years, the first ten being occupied with learning her duties, the next in performing them, and the last in teaching them to others. When she entered upon her office, the Vestal took upon herself a solemn vow of chastity for the thirty years of her service, the dreadful punishment of a violation of which was, that she should be buried alive in a subterranean vault near the Colline gate, to which she was carried on a bier, as if dead, and where she found a light, with a scanty supply of bread, water, milk, and oil. The chief duty of the virgin priestesses was to keep the fire on the altar of the goddess ever burning; they had also to present offerings to Vesta, sprinkle the temple every morning with water drawn from the Egerian well, and guard the sacred relics, which were a pledge granted by fate for the permanency of the Roman sway. As the extinction of the sacred fire was looked upon as emblematic of the extinction of the state, the Vestal who, by neglect of duty, allowed this to happen, was severely punished, the penalty being, that she should be stripped and scourged by the pontifex in the dark; the fire was again rekindled by the friction of two pieces of wood from a "lucky tree."

As a compensation for the strictness of the lives which they had to lead, the Vestals had many privileges bestowed upon them: among others, they were entirely freed from paternal authority; could make a will, and give evidence without taking an oath; had a seat assigned them in the best part of the theater; were held in the greatest honor, and done homage to by the highest officers of the state; and even the plebs, in their most reckless moments, respected them. If, when out walking, their eye should chance to light upon a criminal, he was set free. At the expiration of her period of service, a Vestal, if she chose, could marry, although to do so was considered very unlucky.

VESTIBULE TRAINS. Trains fitted with vestibule connections between the cars. The "vestibule" consists of a frame-plate extension at either end of the cars, completely enclosing the platforms. They are fitted with doors for entry and exit, and with buffers to prevent the racking of the car frames in curves and stoppages. The first vestibuled train between New York and Chicago, made up of five cars, went over the Pennsylvania Central in April, 1887. In December following, a train of six cars was put on the limited line of the New York Central. They became rapidly popular. The space enclosed constitutes in reality an extension of one car into another car, like the openings between drawing-rooms. They are considered much safer than ordinary trains, as in case of collision they are less likely to be "telescoped."

VESTMENTS, Sacred, the peculiar habiliments worn by ministers of religion in the public discharge of their office, and sometimes in other sacred ministrations, even when privately performed. The use of a distinctive costume in public worship formed a part not only of the Jewish, but of almost all the ancient religions, and has been found in a greater or less degree in the religions of the new world. See Lipsius, *De Monument. et Exemp. Polit.*, l. i. c. 3. The whole 28th chapter of Exodus is taken up with a descrip-

tion of the vestments of the high priest; and the directions for those of the inferior functionaries are almost equally minute. Whether the same characteristic was carried into the early Christian worship, has been a subject of controversy; some writers being of opinion that the peculiar sacred costume which we find in use among Christian ministers from a very early period was not originally peculiar to the clergy, but was simply the ordinary costume of Rome and of the east in the first centuries, and only came to be a costume distinctive of sacred ministers, because by them it was retained unaltered, whereas in the every-day world the costume varied in fashion, in material, in color from year to year. There seems little room, however, for doubting, that from a very early time Christian ministers did employ some distinctive dress in public worship; and Catholic writers even find traces in the beginning of the 5th c. of the practice of blessing the vestments which were destined for the public services of the church. See Binterim, *Denkwürdigkeiten*, IV. i. p. 198. From the 8th c. downward, the rituals of the west all contain formularies for the blessing of the several sacred vestments worn by bishops, priests, deacons, and lower clergy. The vestments used in the celebration of the mass by priests of the Roman Catholic church are six in number,—viz. (1) the amice, a square piece of linen, which is worn upon the shoulders, and in some of the religious orders, over the head, which latter, indeed, appears to have been the ancient mode of wearing it; (2) the alb, a long, loose-sleeved, linen gown, sometimes richly embroidered or "apparelled" at the lower border; (3) the cincture, a linen cord tied around the waist, and confining the folds of the alb; (4) the maniple, a narrow strip of embroidered silk, worn pendent from the arm; (5) the stole, a long narrow scarf, similarly embroidered, and worn by priests around the neck, the ends being crossed over the breast or pendent in front, and by deacons transversely over one shoulder; (6) the chasuble, a loose flowing vestment, open at the sides, having a hole in the center, through which the head passes, and falling down over the breast and back to some distance below the knees. Most of these vestments have been already briefly described. The three last named are always of the same material and color; but this color, which appears primitively to have been in all cases white, now, and for many centuries, varies according to seasons and festivals, five different colors being employed in the cycle of ecclesiastical services—viz., white, red, green, violet, and black. Cloth of gold, however, may be substituted for any of these, except the last. A cap, called *biretum*, is worn in approaching the altar, but is laid aside during mass. Besides these vestments, which are worn by priests during the mass, bishops in the same service use also two inner vestments, of nearly the same form as the chasuble, called "dalmatic" and "tunic," as also embroidered gloves and shoes, or buskins, together with the distinctive episcopal ornaments—the pectoral cross, the miter, the pastoral staff, or, if archbishops, the crosier, and ring. Archbishops celebrating mass also wear the pallium (q.v.). Deacons, at the same service, wear a robe, called dalmatic; and sub-deacons, a tunic. The sub-deacon is not privileged to wear the stole. In other public services, priests and bishops wear a large flowing cloak, called cope (Lat. *pluviale*), with a pendent cape or hood, called orfrey. In the ministration of the other sacraments, and also in administering communion, priests wear the surplice (which is but a short alb) with the stole. The vestments of the Greek priests differ considerably in their general character and effect from those of the Latin clergy, but the several portions of the costume are substantially the same as those of the Latin costume already described. The *stoicharion*, the *zoné*, the *orarion*, the *epimanikia*, and the *phelorion*, correspond respectively with the alb, cincture, stole, maniple, and chasuble. Greek bishops wear the *omophorion*, which corresponds with the later pallium. The *phelorion*, however, is so ample in its folds as to resemble the Latin cope rather than the chasuble; and the general effect of the Greek vestments, which may be said to resemble in all particulars that of the other eastern rites, is much more picturesque.

The natural effect of the religious changes of the 16th c. was to put aside the costume at the same time and on the same grounds with the ceremonies of the existing worship. This was done, however, by the different churches of the reformers in very various degrees. The Calvinistic worship may be said to have dispensed with vestments altogether. The Lutherans generally retained with the cassock the alb, and in some countries the chasuble. In the English church a variety of practice has existed. The disputes about the use of the surplice (q.v.) have been already described. As to the rest of the costume, the first prayer-book retained the Roman vestments with little change; and as, by a remarkable accident, the rubric of this prayer-book has never been formally repealed, a so-called ritualistic movement in the English church has re-introduced in some places almost every detail of the Roman costume in the communion and other services. See illus., Priests, Monks, and Nuns, vol. XII.

VESTRIS, the name of a family of dancers of Italian origin. The most famous of them was Madame (Bartolozzi), 1797–1856; b. London; wife of the dancer Auguste Armand Vestris. She made her first appearance in opera in 1815. She was afterward a successful English actress and contralto singer. Her second husband was the younger Charles Matthews. Gaetano Apollino Baldassare (1729–1808; b. Florence) and Marie Auguste (1760–1842; his natural son) were famous opera dancers in their time.

VESTRY, in English parishes, is a meeting of the inhabitants of the parish assembled to deliberate on some matter which they have a right to decide (see Parish). The ves-

try is the regular organ through which the parish speaks; and in numerous matters relating to church-rates, highways, baths, and wash-houses, and other sanitary matters, it has important functions to discharge, and is a conspicuous feature of parochial management. A statute was passed in 1818 to regulate the mode of procedure. No vestry, or meeting of inhabitants in vestry, shall be held until public notice of the place and hour of meeting be given, as well as of the special purpose of such meeting. This notice is required to be given by publishing it on some Sunday before the celebration of divine service, by affixing a written or printed copy on the principal door of the parish church or chapel. Such notice is to be previously signed by a church-warden. In the American Epis. church, the duties of the vestry of a parish differ from those of bodies bearing the same name in the church of England, this difference being due to the separation in this country of church and state. These duties vary according to the canonical law of each diocese, or the by-laws of the several parishes. A committee appointed by the General convention has for a long time had under consideration the most advisable means of reducing these varying duties to uniform practice, thus saving needless confusion and disorder. The vestry have certain well-understood general duties to perform, however, alike in every diocese: they must notify the bishop when their parish is vacated, in order that the services may be maintained; they must inform the bishop of the election of a new rector, because upon the bishop's decision, or that of the standing committee acting in his stead, depends the recognition of the rector's right to the control of his parish; they must give to the diocesan, at his annual visitation, such information as he may desire. The vestry have no control over the spiritualities of a parish; they are merely the legal representatives of the parishioners in the temporal care and financial management of the church organization. The rector gives his resignation to the vestry upon withdrawing from a parish; but the vestry cannot remove him without some urgent cause. In the spiritualities, including the conduct of the worship, he is responsible only to his ecclesiastical superior, viz., his diocesan. The rector, on the other hand, must consult with his vestry before entering upon work involving financial outlay. In consistently regulated parishes, the rector is chairman of the vestry, and has a voice in their proceedings. See *The Rights and Duties of Rectors, Church-wardens, and Vestrymen*, by Rev. H. M. Baum. The word vestry is also applied to a room attached to a church, in which vestments and sacred vessels are kept, and in which parochial meetings are held. In New England the name vestry has been retained by the Congregational churches, and is applied to a room, or separate building, used as a chapel, or "lecture-room."

VESU'VIAN, or IDOCRASE, a mineral, allied to garnet, and sometimes called *pyramidal garnet*. It is found in volcanic and in primitive rocks. It is frequent in masses ejected from Vesuvius, whence its name. The hardness is about equal to that of quartz. The colors are various—yellow, green, brown, almost black, rarely azure. Vesuvian is composed of silica, alumina and lime, in somewhat varying, but not very unequal proportions, with a little oxide of iron and oxide of manganese. It is employed as an ornamental stone, but is not very highly valued. The green-colored varieties are known as *volcanic chrysolite*, and the brown as *volcanic hyacinth*.

VESUVIUS, a well-known volcano, is situated near the e. shore of the bay of Naples, about 10 m. from the city of that name. It is a solitary mountain, rising majestically from the plain of Campania, having at the base a circumference of about 30 m., and dividing, at a certain height, into two summits, Somma and Vesuvius proper. The height of the mountain and form of its apex are subject to frequent changes by eruptions. It is estimated to be at present about 4270 ft. high. In the single eruption of 1822 it lost 800 ft., nearly all of which has been restored by subsequent eruptions. Before that event, the summit was a rough and rocky plain, covered with blocks of lava and scoriæ, and rent by numerous fissures, from which clouds of smoke were given out. But it was then altered to a vast elliptical chasm, 3 m. in circumference, three-quarters of a mile at the greatest diameter, and about 2,000 ft. deep.

The first recorded eruption took place in the year 79 A.D. Warnings had been given sixteen years before by a great earthquake, which shattered the cities of Herculaneum and Pompeii, and the earth was frequently shaken by slight shocks until August of the year 79, when they became more numerous and violent. Previous to this, Vesuvius was not suspected to be a volcano. Its sides were covered with famous vines, and its ancient crater, partly filled with water, formed the stronghold of the rebel chief, Spartacus. The morning of Aug. 24 brought comparative repose; but in the course of the day, a huge black cloud rose from the mountain, from which stones, ashes, and pumice were poured down on all the region around. The elder Pliny, who commanded the Roman fleet at Misenum, sailed to the help of the distracted inhabitants: he landed near the base of the mountain, was enveloped in sulphurous vapor, and was suffocated. The younger Pliny gives a graphic account of the eruption in two letters to Tacitus, which are well known. No lava was ejected on this occasion, nor indeed in any eruption in historic times up to the year 1066. Pompeii was buried under a thickness of 20 ft. of loose ashes, and remained unknown until about a century ago. A torrent of mud spread over Herculaneum, which, by additions from subsequent repeated eruptions, now forms a thickness of 80 or 100 feet. Since this first famous eruption, Vesuvius has been an active volcano, and has been frequently but irregularly in eruption, about 60 great

and numerous smaller ones having taken place. In 472 the eruption was so great that the ashes fell even at Constantinople, and caused great alarm there. The summit known as Monte Nuovo was, in 1538, forced up in two days to the height of 413 ft., and with a circumference of 8,000 feet. In 1631 the villages at the foot of the mountain were covered with lava, and torrents of boiling water were sent forth. Since that described by Pliny, one of the most famous is the eruption of 1779, of which sir William Hamilton, then British minister at Naples, gives an interesting account. In the spring of that year it began to pour forth lava; this was succeeded by rumbling noises and puffs of smoke; then jets of red-hot stones and ashes made their appearance, and increased in number and intensity, until the eruption arrived at its climax between Aug. 5 and 10. Then enormous volumes of white clouds rose from the crater to a height four times that of the mountain, and lava poured from the crater in torrents down the sides of the cone. This was followed by columns of fire, which rose on some occasions to three times the height of Vesuvius, or more than two miles. In the midst of all this, showers of stones, scoriæ, and ashes were thrown out to a great height. One mass of rock ejected was 108 ft. in circumference, and 17 ft. high. A more terrible eruption took place 15 years later, by which the greater part of the town of Torre del Greco was destroyed. The violent eruption of 1822 has already been alluded to. A remarkable eruption occurred in May, 1855. In 1865 began a series of eruptions, which have been repeated at intervals since. For a full account of the fearful outbreak of April, 1872, we are indebted to Palmieri, director of the meteorological observatory on mount Contaroni, a part of Vesuvius, who with great courage remained in the observatory while it seemed threatened with destruction. An eruption much less destructive than that of 1872 took place in 1878, and another in 1880. A railway to the top of V. was opened, 1880.

VESZ'PRIM (Ger. *Weiszbrunn*), a t. in the w. of Hungary, on the Séd, 70 m. s.w. of Pesth. It contains a handsome episcopal palace, a fine cathedral, a Piarist college, gymnasium, and an institution for decayed or disabled priests. Cloth and flannel-weaving, silk-spinning, the cultivation of wine, fruits, and tobacco are the principal industries: but coal-mining, iron-works, large cattle-markets, and general trade are carried on. The town has been on several occasions in the possession of the Turks; and an interesting memorial of them is a slender minaret, which rises from an old Gothic tower, and which now serves as a watch-tower against fire. Pop. '90, 12,655.

VETCH, *Vicia*, a genus of plants of the natural order *leguminosæ*, suborder *papilionaceæ*, having a tuft of hairs on the style beneath the stigma, nine stamens united, and one free. To this genus the *bean* (q.v.) is generally referred. The species, however, are mostly climbing plants, annuals, with pinnate leaves ending in tendrils, and with no terminal leaflet. A number of species are natives of America. The common vetch (*V. sativa*), sometimes called by agriculturists TARE, frequent in cultivated ground in Britain and throughout Europe, and itself much cultivated as green food for cattle, has rather large purple, blue, or red flowers in pairs, axillary and almost sessile. In cultivation it varies considerably both in size and other particulars, as in the breadth of the leaflets, the number of them in a leaf, etc. Oats are generally sown along with it to afford it a little support, and thus prevent its rotting in wet weather.— *V. cracca* and *V. sepium* are very common British species, the former with many-flowered stalks, bearing beautiful bluish-purple flowers, being one of our most beautiful climbing plants, and a chief ornament of trees, hedges, and bushy places in the latter part of summer. These and other species, natives of Britain or of different parts of Europe and the n. of Asia, have been either occasionally cultivated as food for cattle or recommended for cultivation, and generally agree with the common vetch both in their qualities and in the mode of cultivation which they require. *V. biennis* and *V. narbonnensis* are among those chiefly cultivated in some parts of Europe. The species of vetch are very numerous, chiefly in the temperate parts of the northern hemisphere.

VETCH, BITTER. See OROBUS.

VETCHLING. See LATHYRUS.

VETERAN CORPS are among the military reserves of all nations. They consist of old soldiers past the prime of active manhood, and incapable of taking the field. Their discipline and steadiness, however, admirably fit them for garrisons or fortresses, and for the instruction of young troops. The veteran battalions did good service during the French war as home guards, releasing the active troops for foreign service. The English army estimates for 1891 made provision for an army reserve (including pensioners) of 63,980 men. But from the short periods during which men serve as soldiers, and the number of officers who quit the army on reaching the rank of captain, it is almost certain that very large veteran corps could be formed from civil life in any case of national emergency.

VETERAN RESERVE CORPS, in the United States, an organization established during the civil war, but now discontinued. It was composed of men honorably discharged on account of wounds or disabilities, of men absent from their colors in hospitals or convalescent corps, and of men disabled by wounds or disease, but still in the field. In May, 1865, the body consisted of 762 commissioned officers and 29,852 men. The duties of the veteran corps were varied, and included such work as hospital and gar-

rison service and patrol duty. They were serviceable in taking the place of efficient soldiers who were needed in the field.

VETERINARY MEDICINE (Lat. *veterina*, beasts of burden; probably for *vehiterina*, from *veho*, to carry) embraces the medical management of the domestic animals, and appears to have been studied by the ancient Egyptians as well as by the Greeks and Romans. Hippocrates contributed a treatise on equine disorders; Columella and Vegetius (the latter of whom flourished about 300 A.D.) have left several curious veterinary works. Until after the middle of the 18th c. there were, however, no schools for the teaching of veterinary science or art. The several works published in France, Italy, and elsewhere were not of great value. In this country, Blundeville and Gervase Markam, who lived in the reign of Elizabeth, published volumes on farriery; Snape, farrier to Charles II., produced an anatomical treatise on the horse; Mr. Gibson, previously a surgeon in a cavalry regiment, paid much attention to the disorders of animals, and about the middle of last century published *The Farrier's Guide*, which continued for many years the best authority on the subject. The treatment of sick horses remained, however, in the hands of the riding-master, the groom, or the shoeing-smith, or farrier (from *ferrum*, iron); while the doctoring of the other domestic animals devolved upon the goat-herd, shepherd, or cow-leech.

Veterinary medicine, as a scientific art, takes date from 1761, when the first veterinary college was established at Lyons with royal patronage, under the able teaching of Bourgelât. Five years later the flourishing school of Alfort, near Paris, was founded. In Feb.. 1791, the London college was organized, Charles Vial de St. Bel being appointed principal, with Delabere Blaine as assistant-professor. St. Bel died in 1793, and was succeeded by Mr. Coleman, who, during many years, zealously improved the position and teaching of the college. In Scotland lectures on veterinary medicine were first given by Mr. Dick in 1819. Under the auspices of the Highland and agricultural society, and senatus academicus, Mr. Dick in 1823 began his systematic teaching of veterinary surgery. Soon afterward he erected the college buildings in Clyde street, Edinburgh, with hospital for sick animals; he collected a valuable museum; extended the curriculum of study; and engaged efficient assistants, among whom were John Barlow and Dr. George Wilson, to instruct his pupils in anatomy and physiology, chemistry and materia medica, cattle practice and histology. At his death in April, 1866, Mr. Dick bequeathed to the city of Edinburgh the college which he had founded, and his entire fortune, to be devoted to the teaching and improvement of veterinary medicine. For many years upward of 80 professional pupils, with a number of agricultural and amateur students, have annually attended the classes at the Edinburgh veterinary college. About 150 are enrolled at the Camden Town college, London. In 1857 Mr. John Gamgee established the new veterinary college in Edinburgh, which existed till 1865, when Mr. Gamgee went to London. The new veterinary college, Gayfield house, Edinburgh, was established by principal Williams, and recognized by royal sign manual in 1873. Since 1861 a veterinary school has been conducted in Glasgow by Mr. James Macall. An attendance at one or other of these colleges, during three sessions of six months each, and two sessions of two months, is required before a pupil can present himself to be examined for his degree. At the best continental schools four years study is usually necessary. The fees for the whole curriculum at the different educational establishments are about 36 guineas. At all the colleges—at London by the college of preceptors; at Edinburgh by the rector of the Royal high school and mathematical master; at Glasgow by the principal of the college—a preliminary examination is now required.

In 1844 a royal chapter was granted under which veterinary surgeons (graduates of either the London or Edinburgh college) became a corporate body, entitled "The Royal college of veterinary surgeons," with authority to appoint examining boards, and grant diplomas or licenses to practice. In 1876 a supplementary charter was obtained, empowering the Royal college of veterinary surgeons to grant the higher title of fellow, without examination, to the most eminent members of the profession who had been fifteen years in practice, and to appoint a board to examine candidates for the fellowship degree, each candidate to have been five years in practice. Nearly 3,000 persons now hold these diplomas, which cost £10 10s., and constitute the holder a member of the Royal college. For many years the Highland and agricultural society of Scotland annually appointed an examining board, consisting of medical men and skilled veterinarians; and at the cost of £2 2s., granted to pupils who had studied for two sessions at the Edinburgh veterinary college, a certificate which was ever fully recognized as a guarantee of professional ability by the public, and by the authorities at the horse guards and India office. The first veterinary college in the United States was the Boston (Mass.) Veterinary Institute, established in 1855, though no instruction was ever given there. In 1857, the New York College of Veterinary Surgery was chartered. The American Veterinary College was founded by professors who seceded from the New York College of Veterinary Surgery. The institution is still prospering, and has in connection with it a veterinary hospital. The professors are all graduates in medicine. Some of the agricultural colleges of this country have chairs of veterinary surgery and grant degrees in veterinary science.

The literature of veterinary medicine is rapidly widening. Mr. Percivall and Messrs

Gamgee and Law, and the late Prof. Strangeways, have published text-books on anatomy. The chief reliable authorities on diseases consist of Mr. Dick's excellent little manual of veterinary science; Percivall's *Hippopathology*, in 3 vols.; Mr. Gamgee's *Domestic Animals in Health and Disease;* F. Dun's *Veterinary Medicines, their Actions and Uses, with an Appendix on Diseases of Animals;* Tuson's *Pharmacy.* Late important contributions are Prof. Williams's *Principles and Practice of Veterinary Surgery* (Edinburgh, 1872); and *Principles and Practice of Veterinary Medicine* (Edinburgh, 1874), which have now reached their third and second editions. Mr. Fleming, v.s., r.e., has translated M. Chaveau's elaborate treatise on the *Anatomy of the Domesticated Animals* (1873); has published *Sanitary Science and Police*, 2 vols.; *Rabies and Hydrophobia; Animal Plagues; Veterinary Obstetrics;* and founded *The Veterinary Journal.* The *Veterinarian*, a monthly periodical, has been published for many years.

VETERINARY SURGEON (Eng.), an officer of a cavalry regiment, or in the artillery, who is charged with the supervision of the horses, and with their cure, if in need of medical aid. A veterinary surgeon is required to produce proper testimonials of qualification, and to pass an examination. On appointment he receives 10s. a day, and ranks as lieut. By service his pay rises to £1 3s. a day, and his relative rank to that of maj. After 25 years' service he becomes entitled to retire on half-pay.

VETH'AKE, Henry, ll.d., 1792–1866; b. Essequibo, South America; came in youth to the United States; graduated at Columbia college, 1808; studied law; was a teacher of mathematics and geography in Columbia college, 1813; professor of mathematics and natural philosophy Rutgers college, 1813–17; at Princeton, 1817–21; Dickinson college, 1821–29; university of New York, 1832–35; president of Washington college, Va., 1835–36; professor of mathematics, university of Pennsylvania, 1836–54; provost, and professor of mental and moral philosophy, 1854–59; professor of higher mathematics in the Philadelphia polytechnic college, 1859. He published *Principles of Political Economy;* edited *Supplementary Volume of Encyclopædia Americana*, most of the articles of which he wrote; edited and enlarged McCulloch's *Dictionary of Commerce.*

VETIVER, or **Cuscus**, the dried roots of an East Indian grass (*Andropogon muricatus*), which has a very agreeable and persistent odor, something like sandal-wood. It is much prized in India and other parts of the world, and is used to perfume linen, etc. Baskets, fans, and mats are made of it in India; it is remarkable for giving out its perfume for many years, and it is strongest when moistened.

VETO, in politics, the power which one branch of a legislature of a country may have to negative the resolutions of another branch. In the United Kingdom, the power of the crown in the act of legislation is confined to a veto—a right of rejecting, and not resolving. The crown cannot of itself make any alterations in the existing law, but may refuse to sanction alterations suggested and consented to by the two houses of parliament. The necessity for such refusal is generally obviated by an observance of the constitutional principle, that the will of the sovereign is that of the responsible ministers of the crown, who only continue in office so long as they have the confidence of parliament. The royal veto is reserved for extreme emergencies; the last instance in which it was exercised was in 1707, when queen Anne refused her assent to a bill relating to the militia in Scotland. The house of lords will generally support the prerogative of the crown by rejecting a measure repugnant to the sovereign; and a knowledge of this may enable the ministry to defeat it in the house of commons—a result which the constitutional influence of the crown and the house of lords in the lower house may assist in producing, so as to avoid a collision between the branches of the legislature. In bills of supply, the power of the house of lords amounts merely to a veto, as does that of the house of commons in bills affecting the peerage.

In the French constitution of 1791, it was resolved to have but a single house of legislature, on the principle that it was inconsistent with the idea of a legislature representing the national will that one part of it should have a veto on another, and the same view was adopted by the convention of 1793. But the arbitrary and violent measures of that latter body induced a strong general conviction that a division of the legislative power, and a veto in some form, was essential to give stability to the government, and moderation to faction; and in the constitution of 1795, a council of ancients was introduced, with a power to veto the resolutions of the legislative body.

By the constitution of the U. S. power is given the president to "veto" any act of congress by refusing to sign the bill after its passage. If he adopt this course the bill is returned to the house in which it originated with the president's objections to signing it. The house then may proceed to reconsider the act, and if the act pass both branches by a two-thirds majority, it becomes law. A similar power is exercised by the governors of the states under the state constitutions. The U. S. constitution also provides that "if any bill shall not be returned by the president within ten days (Sunday excepted) after it shall have been presented to him, the same shall be a law in like manner as if he had signed it, unless the congress by their adjournment prevent its return, in which case it shall not be a law." This power of the president to prevent the enactment of a law presented to him within the ten days before the adjournment of congress, without sending in a refusal to sign or objections, is commonly known as the "pocket veto." In a few states, a simple majority vote will carry a bill over a governor's veto.

VETO ACT, in Scottish ecclesiastical law. See PATRONAGE; SCOTLAND, CHURCH OF.

VEUILLOT, LOUIS, French journalist and author, b. in 1813, at Boynes en Gatinais (Loiret). The son of a small cooper, he was sent to a school near Paris, from which he was transferred in 1826 to a lawyer's office. He chose the profession of journalism, and filled several engagements on the provincial press, in the course of which his personalities involved him in various duels. He visited Rome in 1836, previous to which, he states, he was without much faith, either religious or political. He returned to Paris, however, a zealous adherent of the papacy, and, as editor of the *Univers*, soon signalized himself as an aggressive and uncompromising champion of the church. In 1842 he accompanied marshal Bugeaud to Africa as his secretary, and on his return was made chief secretary to the ministry of the interior. He again edited the *Univers* in 1848; but his polemical disquisitions brought upon him the censure of the archbishop of Paris; and in 1853 the clergy of the diocese of Orleans were expressly forbidden by their bishop to read the *Univers*, which, after the usual three warnings, was suppressed by the French government in 1861. It was afterward replaced by the *Monde*, in which Veuillot discussed religious matters in a more temperate spirit. In 1862, he published a pamphlet, under the title of *Parfum de Rome*, which was principally devoted to heaping coals of fire on the head of Cavour, and assailing the abbé Passaglia with the bitterest objurgations. He prays, for instance, that "his robe may become a robe of fire," and that Heaven "may refuse him a single tear to temper its burning." In 1867, the *Univers* was revived. Veuillot, besides polemical pieces, has written novels, hymns, and a collection of articles under the title of *Mélanges Religieux, Historiques, et Littéraires* (1857). *Les Odeurs de Paris* appeared in 1866. He became an enemy of all progress, and was latterly a furious Legitimist. He d. 1883.

VEVAY (Ger. *Vivis*), a small town of Switzerland, in the canton of Vaud, remarkable for the beauty of its situation on the north shore of the lake of Geneva, at the mouth of the gorge of the Veveyse, 11 m. e. of Lausanne. From the elevations about the town, the fine view to the e. commands the gorge of the Rhône, backed by the magnificent rampart of the Alps of Valais. In the church of St. Martin (date 1438), Ludlow, one of Charles I.'s judges, and Broughton, who read to him his sentence of death, are buried. An electric railway connects Vevay with the famous castle of Chillon (q.v.), 6 m. to the s.e. The country in the vicinity, especially that between Vevay and Lausanne, is much occupied by vineyards and orchards, and the wines of the vicinity have some reputation. Pop. '88, 25,664.

VEZIN, HERMANN, actor, b. in Philadelphia in 1829; was of German parentage, his father being a noted merchant of that city. He was intended for the legal profession, and received the degrees of B.A. and M.A. from the University of Pennsylvania. Following his inclinations, however, he went to England and obtained an engagement at the Royal theater in York. His London *début* was made at the Princess theater under Mr. Charles Kean's management. Two years later he "starred" through the English provinces. In 1857 he visited the United States professionally, returning to England in 1858. He appeared at the Surrey theater, London, in 1859, in various Shakespearian characters. In 1866 he made a great success in *Dr. Davey*. He won immense applause in 1875 by his impersonation of Jacques in *As You Like It*. He also made a great impression as *Macbeth*. At the Haymarket, London, he played *Daniel Druce* 106 times. He also played as Hamlet, Othello, Shylock, Marc Antony, De Talde in *The Danicheffs*, Dr. Primrose in *Olivia*, etc.

VIA DOLOROSA is a narrow, zigzag street in Jerusalem (q.v.), leading from the eastern or St. Stephen's Gate to the Church of the Holy Sepulchre (see HOLY PLACES), and tradition points to it as the street through which our Saviour carried his cross from the Hall of Judgment to Mt. Calvary. It has borne its present name but a few centuries, and its identity with the road connected with the events of the crucifixion, is generally considered by travelers and scholars to be a myth of the Middle Ages. The traditional part commences at the Palace of Pilate, now used as the Governor's palace. Two arches at this point are said to mark the staircase to the Judgment Hall. Next comes the Church of the Flagellation, said to mark the spot where Christ was scourged, though some say this marks the spot where he was crowned with thorns. Next comes the Ecce Homo Arch, said to mark the place where Pilate stood when he said to the Jews, "Behold, I bring him forth unto you that ye may know that I find no crime in him." Dr. Thompson says "there is not a yard of the walls on either side of this street that existed at the time of the crucifixion, still, the arch is a striking object. It is high, quite round, spanning the entire width of the street, and having an ordinary room on top of it, much dilapidated. It will always attract the attention of the pilgrim and the traveler." The next site marked is said to be where he fainted under the cross; next, where he met his mother, saying, *Salve, Mater!* Next comes a steep, sharp pitch on which he is said to have fainted and fallen the second time; next, the spot where Veronica (q.v.), gave him her veil to wipe away the perspiration; and lastly, the place of the third fall. But since history records the total destruction of Jerusalem by Titus in the first century A.D., we must agree with Dr. Thompson when he says, "that whole street, with all its sacred places, I give up at once, as no plausible evidence can be deduced for the identity of any of the stations."

VIADUCT, a structure for conveying a roadway across a valley or low level, being so called in distinction from an *aqueduct* (q.v.), which is an erection of the same description for the conveyance of water over a hollow. It is in every respect similar to an extended bridge. The great extension of railways within recent years has rendered the use of viaducts much more common than formerly. These are of every kind of construction—of wood, iron, stone, and brick work (see BRIDGE, TUBULAR BRIDGE, LATTICE BRIDGE, etc.). A railway embankment is also a species of viaduct; but the term is limited to those structures which are more or less open, and rest upon piers. A very peculiar example is that over the Moine, near Nantes in France. The piers are all perforated by a pointed arch, which insersects the main cylindrical arches, and forms a groined roof, similar to that of a Gothic cathedral. This viaduct consists of 15 arches, and is 348 ft. in length, and is all built of fine granite.

VIA-MA'LA, a remarkable defile in the canton of Grisons, Switzerland, is a portion of the Hinterrheinthal (see RHINE) which lies between Thusis and Zillis. The sides of the cleft, which is about 2 m. in length, are immense walls of rock, almost parallel to each other, and so hard that the disintegrating influence of the elements appears not to have produced the slightest effect on them, each projection on one side corresponding to an indentation on the other, almost as perfectly as at the time they were separated. The walls have a maximum height of about 1600 ft., and at various parts of the defile are not more than ten yards apart at the top. Far beneath, the Hither Rhine, compressed till it appears to one above like a mere thread, rushes like an arrow through the gorge. The first part of this defile was long deemed quite inaccessible, and had received the name of the Lost Gulf (Fr. *Trou perdu;* Ger. *Verlorenes Loch*), but in 1822 a magnificent road was constructed along the whole length of the defile, from 400 to 600 ft. above the river, by blasting and cutting a "notch" in the side of the rock. The road is necessarily steep and narrow, crosses from side to side of the defile by three bridges, and is protected now by a canopy of rock overhead, and again by a wooden roofing, from falling stones and trees. So narrow is the crevasse in some places, that fallen trunks and stones are often wedged in between its sides at a considerable distance above the ordinary water-level; and on the occasion of the great flood of 1834, the river, which is generally 400 ft. below the second bridge, rose to within a few feet of it, and at the same time carried off the upper bridge.

VIAN'NA DO CASTELLO, a fortified city and seaport in the n. of Portugal, in the province of Minho, stands at the mouth of the Lima or Limia, 40 m. n. of Oporto. It is handsome and clean, with a tolerable harbor, which admits vessels of 150 tons burden; and it carries on considerable trade with Newfoundland in salt-fish. Pop. '90, 9682.

VIARDOT, LOUIS, b. France, 1800; became director of Italian opera in 1839, and brought out Michelle Pauline Garcia, whom he married the next year. In connection with George Sand and Pierre Levoux he established the *Revue Indépendante* in 1841. Among his works, which include several translations from the Spanish, and the Russian of Turgeneff and Pushkin, are *Essai sur l'Histoire des Arabes et des Maures d'Espagne* (1832); and *Les Merveilles de la Peinture* (1868). He d. 1883.

VIARDOT-GARCIA, MADAME MICHELLE PAULINE, vocalist, b. in Paris, France, July 18, 1821, was daughter of the tenor Emanuel Garcia, and sister of Madame Malibran. At four years of age she spoke four languages; at seven she was able to play pianoforte accompaniments for pupils to whom her father gave lessons. She was taken with her family first to England, then to the United States, but in 1828 returned to Europe, and her education was continued at Brussels, Belgium, under care of her mother, her father having died in 1832. She was one of Liszt's most accomplished pupils. Her first London appearance was at the Opera House, in 1839, as Desdemona. At the close of the season she joined the Italian Opera Company then at the Odeon in Paris, and was successful. She married M. Louis Viardot, director of the Paris Italian Opera in 1840, who died in 1883. In 1841 she reappeared in England, next appeared at Vienna, then at St. Petersburg, and Berlin. Her name is associated with the first performance of Meyerbeer's *Les Huguenots* and of *Le Prophete*. Her voice combined the two registers of soprano and contralto. She retired from the stage in 1863; began teaching singing in Paris in 1871; and published several compositions.

VIAREGGIO, a t. of central Italy, in the province of Lucca, close to the shore of the Mediterranean, 30 m. s.e. of Spezia. It is modern, stands in a delightful plain, and has wide straight streets. At the beginning of the present century it consisted of only a few huts; but its healthy, equable climate, and fine situation, have induced many rich families to settle here, and it is growing rapidly. Its sea-baths are much frequented. The vicinity is productive in olives, grapes, etc. In 1892 a monument was erected to the poet Shelley, who was drowned near Viareggio in 1822. Pop. '81, 12,735.

VIATICUM (Lat. *viaticum*, money allowed for a journey), the word applied in the ancient as well as modern ecclesiastical terminology to the communion administered to dying persons, which, in the case of the great journey to eternity, is thus quaintly likened to the money-provision made for a journey upon earth. The special ministration of the eucharist to the dying is very ancient (see LORD'S SUPPER); it was the one exceptional case in which, during the times of rigorous canonical penance, the penitents were admitted to the communion before the completion of the appointed cycle of penance.

By the modern practice of the Roman church, it is permitted to the sick, to whom the eucharist is administered in the form of the viaticum, to receive it, although not having fasted (as is required in all other cases) from the midnight previous. The viaticum may be given frequently during the same sickness, at intervals anciently of ten or seven days, but, by the modern practice, even daily, should it be earnestly desired by the sick person. The priest is ordered to bring the sacred elements from the church to the dying person at any hour, whether by day or by night, when he may be called on for this last service of religion. Protestants reject the very idea of a *viaticum*, and regard the administration of the Lord's supper in that character as superstitious.

VIATKA or VYATKA, a government of the e. of European Russia, bounded on the e. by the governments of Perm and Orenburg, and on the s. by that of Kazan. Area, 59,235 sq. m., pop. '94, 3,120,424. The surface consists for the most part of marshes and sandy plains, varied here and there by hills. The soil, fertile only in the southern districts, is mostly a mixture of sand and clay. In the s., agriculture is effectively carried on, wheat, rye, barley, and oats being produced in abundance, as well as flax and hemp, which supply materials for the linen manufactures. The principal rivers are the Viatka and Kama (navigable throughout the whole year), and their affluents. Owing to the number of navigable streams, and to the well-regulated land communications, the traffic of the government is successfully carried on. Horses of a fine breed are reared, but the principal source of the wealth of Viatka is its timber. Iron-works, distilleries, tanneries, and glass and cotton factories are in operation.

VIATKA, a t. of Russia, capital of the government of the same name, on the river Viatka, 280 m. n.e. of Nijni-Novgorod. It was founded by the inhabitants of Novgorod, and was annexed to the Muscovite dukedom in 1489. It has over 20 churches, 2 convents, a public library and museum. The chief branches of industry are the preparation of skins and the manufacture of tallow and wax-candles. Pop. '94, 24,615.

VIAUD, LOUIS MARIE JULIEN, was born at Rochefort, France, Jan. 14, 1850, educated at the Borda school, and admitted into the navy in 1867. He was in the Oceanica, Japan, Senegal, and Tonkin campaigns, and was appointed a lieutenant in 1881. In 1883 the Paris *Figaro* printed a series of letters descriptive incidentally of cruelty at the assaults on the forts of Hué by French soldiers. They were signed "Pierre Loti." The government declared them untrue, unpatriotic, and unbecoming an officer, and condemned Lieut. Viaud to be suspended for a year. They made the writer famous. Viaud wrote, in 1879, *Azivadé;* in 1881, *Rarahu*, reprinted as the *Mariage de Loti*, and the *Roman d'un Spahi*. He wrote, in 1885, *Fleurs d'Ennui*, *Pasquala*, *Ivanovitch*, *Suleima*. But these and the best work of Loti, *Mon Frère Yves*, published in 1883, might have passed unnoticed, except by men of letters, if it had not been for the *Figaro* affair. In 1884 appeared the *Trois Dames de Kasbah;* in 1886, *Le Pêcheur d'Islande;* in 1887, *Mme. Chrysanthème* and *Propos d'Exil;* in 1889, *Japoneries d'Automne;* in 1890, *Au Maroc;* in 1892, *Fantôme d'Orient;* in 1893, *Matelot;* in 1895, *Le Désert;* in 1896 *La Galilée* and *Jérusalem;* in 1897, *Ramuntcho*. In 1891, he was elected to the French Academy.

VIAZMA, a t. of Great Russia, in the government of Smolensk, and 152 m. e. of Moscow, on the Viazma. It is first mentioned in 1239, and, after being owned successively by the Lithuanians and Poles, it finally became Russian in 1634. In 1812, after a bloody battle between the Russian and French armies, in which the former was victorious, Viazma was demolished, and there are now hardly any remains of the old town. It carries on an active trade in corn, flax, hemp-seed, tallow, etc., and is the entrepôt for goods exported to St. Petersburg and Riga. Viazma gingerbread is exported to all parts of the empire. Pop. '93, 16,791.

VIBERT, JEHAN GEORGES, a French portrait and genre painter, both in oils and water-colors, was born at Paris in 1840, studied under Picot and Barrias, and became a chevalier of the Legion of Honor. Among his works, some of which satirize the clergy, are, *The Christian Martyrs among the Lions*, *Daphnis and Chloe*, *The Comedy*, and *Committee on Moral Books*. He wrote a number of plays and monologues, and published *La Science de la peinture* (1891).

VIBI'CES. This term is applied in medicine to patches on the skin, varying in tint from bright red to violet, which occur in certain diseased conditions of the blood, and especially in purpura. They are caused by minute hemorrhages of the capillaries of the true skin. The word is a Latin one, being the nominative plural of *vibex*, *-icis*, the mark of a stripe.

VIBORG, a län of Finland, Russia, having the gulf of Finland for its s. boundary; area, including numerous small islands off the coast; 16,510 sq. m.; pop. '87, 330,823. It contains a part of lake Ladoga and lake Saima. Agriculture is not highly developed, but oats, rye, barley, flax and hemp are raised to some extent. There are numerous manufactories, of glass, porcelain, gunpowder, paper and metal ware, and a heavy trade in timber. It contains a strong fortress at Frederickshamn, on the bay of Finland, where the treaty of 1809 was concluded between Russia and Sweden, in which Finland with Lapland and the Aland islands was made over to Russia. Capital, Viborg.

VI'BORG, the oldest city in North Jutland, and one of the oldest in Denmark, on a small lake, 25 m. w. of Randers. Its most important building is the cathedral, originally founded in the 12th c., and magnificently restored in 1864–76. Pop. '90, 8352 engaged in the manufacture of woolen fabrics, leather, and tobacco.

VIBRATO, an Italian term denoting an effect similar to tremolo. On stringed instruments it is produced by the quick oscillation of the hand while the finger is stopping a note. A kind of trembling sound is made. In vocal music it is a partial suppression and reinforcement of a note, producing an apparent reiteration.

VIBRION'IDÆ, a family of microscopic organisms, which derive their name from their darting and quivering motion. They are allied to the Bacteria (q. v.), from which they differ in being jointed. It has been debated whether they are animal or vegetable. See GENERATION, SPONTANEOUS: also GERM THEORY.

VIBURNUM, a genus of plants of the natural order *caprifoliaceæ*, having a 5-toothed calyx, a 5-lobed, wheel-shaped, bell-shaped, or tubular corolla, 5 stamens, 3 sessile stigmas, and a one-seeded berry. The species are shrubs with simple leaves, natives chiefly of the northern parts of the world. *Viburnum opulus* is the guelder rose (q.v.), or snowball tree, and *viburnum laurustinus* is the laurustinus (q.v.), both well-known ornamental shrubs. *Viburnum lantana*, sometimes called the WAYFARING TREE, is a native of the warmer temperate parts of Europe and Asia, not unfrequent in England, and often planted as an ornamental shrub. It is a large shrub or low tree, with large elliptic serrated leaves, downy, with star-like hairs on the under side. The young shoots are very downy. The flowers are small and white, in large dense cymes; the berries purplish black, mealy, and mucilaginous, with a peculiar sweetish taste, disagreeable to many, but relished by some. They are useful in diarrhea and catarrh. Birdlime is made from the roots in the s. of Europe. The inner bark is very acrid, and was formerly used as a vesicant. The wood is white and hard, and is prized by turners. Tubes for tobacco-pipes are made of the young shoots.—Two North American species, *viburnum edule* and *viburnum oxycoccus*, nearly allied to the guelder rose, produce berries of an agreeable acid taste, which are used like cranberries. See illus., BOTANY, vol. II.

VICAR (Lat. *vicarius*, from *vicem*, i.e., *gerens*, acting in the place of another), the title given to the substitute, whether temporary or permanent, employed to act in the place of certain ecclesiastical officials, whether individuals or corporations; as of the pope, a bishop, a chapter, a parish priest, etc. Vicars take different names from these various considerations. Vicars of the pope are called "vicars-apostolic," and they are generally invested with episcopal authority, in some place where there is no canonical bishop. Vicars of a bishop are either "vicars-general," who have the full authority of the bishop all over his diocese, or "vicars-forane" (Lat. *foraneus*, from *foris*, abroad), whose authority is confined to a particular district, and generally otherwise limited. A vicar-capitular is the person elected by the chapter of a diocese, during the vacancy of the see, to hold the place of the bishop, and to exercise all the authority necessary for the government of the diocese. The vicar-capitular, however, is not competent to do any act of episcopal order, as ordination, confirmation, etc. His power is restricted in other ways which it would be out of place to detail here. Parochial vicars are either perpetual, as in parishes which were anciently held *in commendam* (q.v.), or which were held by religious corporations; or temporary, whose appointment may be recalled at pleasure, or after a fixed time. The name, in this sense, is sometimes given, especially in the Roman Catholic church, to the assistant-priest, or as he is called in England, the curate, in a parish. The functions of "vicars-apostolic" are described under the head IN PARTIBUS INFIDELIUM.

VICE, SOCIETIES FOR THE SUPPRESSION OF, are organizations formed mainly "to suppress and repress evils which especially attack the morals of the young—obscene, indecent, and criminal books and pictures and papers, articles for indecent and immoral use, and all kinds of gambling." They have full power to enforce the laws, to prosecute offenders, and to destroy their stock.

VICE-ADMIRAL. See ADMIRAL and FLAG-OFFICER.

VICE-CHAMBERLAIN. See CHAMBERLAIN, LORD.

VICE-CHANCELLOR, a judge in equity, appointed by the crown under letters-patent to assist the lord chancellor of England. The title and functions are at least as old as the reign of Henry II.; but the office long fell into disuse, and was revived by statute 53 Geo. III. c. 24, appointing one vice-chancellor; act 5 Vict. c. 5, s. 19, afterward appointed two more, on the abolition of the equitable jurisdiction of the court of exchequer. The office is ancillary to that of the lord chancellor, for whom the vice-chancellor is empowered to act in his absence, besides being entitled to hold separate courts.

The vice-chancellor of a university is an officer who is empowered to discharge certain duties of the chancellor, chiefly those connected with granting degrees, in his absence.

VICE-CONSUL, a subordinate officer, to whom consular functions are delegated in some particular part of a district already under the supervision of a consul. A British vice-consul is selected by the consul under whom he is to act, and his name is transmitted for approval to the secretary of state for foreign affairs. If he is approved of, the consul is directed to furnish him with authority to act, and to impart to him instructions similar to what he himself has received from the foreign secretary. The vice-consul acts

under the general supervision of the consul, corresponding with him in ordinary cases, but in some special cases with the foreign office. A consul is not at liberty to dismiss a vice-consul acting within his district without the sanction of the foreign secretary; but if of opinion that sufficient grounds for the dismissal exist, his duty is to give information to the foreign secretary, suspending the vice-consul in the mean time, if the circumstances be urgent; and in all cases awaiting the decision of the foreign secretary before taking ulterior steps. Regarding U. S. vice-consuls, the general usage is the same.

VICE-PRESIDENT, an officer of the U. S. government, whose official function consists in presiding over the senate, where he can vote only in case of a tie, and who succeeds to the presidency upon a vacancy in the latter office. He is elected with and in the same way as the president; and if there has been no election of a vice-president by the electors, a majority vote in the senate, if there be a quorum of two-thirds present, will elect him. In the absence of such a majority he is elected from the two candidates receiving the largest senatorial vote. His salary is $8000.

VICENNIAL PRESCRIPTION, in the law of Scotland, is the limitation which is put to certain actions after the lapse of 20 years, such as actions by heirs to reduce an erroneous retour.

VICENTE GIL. See Gil, Vicente.

VICENZA, a province in n.e. Italy, adjoining the Tyrol, drained by the Brenta and the Bacchiglione rivers; about 1000 sq. m.; pop. '93, 440,191. The surface is generally level, except in the n. where it is intersected by ridges from the Alps. There are large forests. The soil in the level districts is fertile. The chief productions are cattle, silk, and wool. Coal is found. There are extensive manufactures. Capital, Vicenza.

VICENZA, a handsome city of Venetia, beautifully situated at the confluence of the Bacchiglione and Retrone rivers, 42 m. w. of Venice by railway. The rivers are crossed by numerous bridges, one of which, a bold, single arch, is attributed to Palladio, who was a native of the city, and to whose genius it is much indebted for its beauty. Vicenza is surrounded by a moat, and walls half in ruins, and contains many fine palaces and churches. The Piazza dei Signori, a remarkably fine square, contains the Palazzo della Ragione or town-hall, an early building in the pointed style, surrounded by the Basilica Palladiana, a beautiful colonnade in two stories, with a slender campanile over 265 ft. high. The Palazzo Prefettizio, also by Palladio, is a rich and fanciful Corinthian edifice. The Duomo, built in 1467, is Gothic; the nave of it is 60 ft. wide; and in certain of the chapels are interesting pictures. The Teatro Olimpico, the scenery of which is fixed, and represents a species of piazza, with diverging streets of real elevation, but diminishing in size, is by Palladio. Vicenza contains a lyceum, a seminary, and a picture gallery; an extensive library, and a hospital, and many benevolent institutions. Manufactures of silk, linen, earthenware, paper, and velvet are carried on. The surrounding country, studded with mansion-houses, and rich in vineyards, is exceedingly beautiful. Pop. '95, commune, 41,200.

Vicenza (anc. *Vicentia*, or more correctly, perhaps, according to inscriptions, *Vicetia*) is a very ancient city. An inscription records its existence in 136 B.C., and it continued to be a municipal town of some consideration, till it was laid waste by Attila, 452 A.D. It revived again under the Lombards, and became for a time, in the middle ages, an independent republic.

VICEROY (Lat. *vice*, in place of, and Fr. *roi*, king), a title popularly given to any officer who is delegated by a sovereign to exercise regal authority in his name in a dependency, as the lord-lieutenant of Ireland—who, however, is never officially so styled. It was the proper official designation of the governors of Naples, Spain, and Peru, under the old Spanish monarchy. See Khedive.

VICH, or Vique, a city of Spain in Catalonia, modern province of Gerona, on a hill-girt plain about 38 m. n. of Barcelona. Its cathedral, built about 1040, but repaired and modernized about the end of the 18th c., is bold and elegant in the interior, and the Gothic cloisters are of the most rich and elegant description. Corn, fruit, and a bad wine are the products of the vicinity; and the inhabitants are employed in weaving, and in the manufacture of hats and paper. Pop. '87, 11,640. Vich, the Roman *Ausa*, was afterward called *Ausona* and *Vicus Ausonensis*, of the first part of which its present name is a corruption.

VICHY, a small t. of the interior of France, in the department of Allier, stands on the Allier, in a fine valley, surrounded by hills clad with vines and fruit trees, 32 m. s.s.e. of Moulins. Pop. '91, commune, 10,870. Vichy is the most fashionable bathing resort in France. The springs which rise at the foot of the volcanic mountains of Auvergne (q.v.) are of the alkaline class, and the most efficacious of the kind that are known. They vary in temperature from 68° to 112° Fahr., and are used both for drinking and bathing. They are resorted to in cases of indigestion, chronic catarrh, gout, etc. See Mineral Waters.

The virtues of the *aquæ calidæ* of this place were known in Roman times, as is testified by the numerous remains of marble baths and coins of the times of Claudius and Nero that have been dug up; but their modern repute arose only in the present century.

VICIA. See Vetch and Bean.

VICKSBURG, city, port of entry and delivery, and co. seat of Warren co., Miss.; on the Mississippi river, and the Queen and Crescent route and the Yazoo and Mississippi Valley railroads; 45 miles w. of Jackson. It was settled in 1836 by a family named Vick, and was incorporated in 1840. It was strongly fortified in 1861, after the adoption by the state of the ordinance of secession, and was provided with a large garrison, which refused to surrender at the demand of a portion of Farragut's fleet, May 18, 1862, and the fortifications and city were taken only after a long siege, as related in the article following. The efforts of Gen. Grant to change the river channel by cutting a canal across a peninsula in front of the city, failed for the time, but in 1876 the river broke through at that point, forming De Soto island and Centennial lake. Since then extensive operations have been carried on by the U. S. government to prevent further erosion on the Louisiana bank and to provide a permanent channel for the river, with the view of restoring navigable water to the city front. The city is built upon the Walnut Hills, a high range extending through the Yazoo valley, and presents a very picturesque appearance from the Mississippi.—It is regularly laid out and contains some handsome buildings, the court-house in particular, but the older streets are narrow. It is the chief commercial point, especially for cotton, between Memphis and New Orleans, and is connected with those ports and with St. Louis by lines of packets, as well as by rail. Besides baled cotton it ships large amounts of cotton-seed oil, oil-meal, and oil-cake, and its manufactures include machinery, cars, boilers, lumber, sashes, doors and blinds, iron, carriages, and shoes. It has a U. S. government building, co. court-house, the Charity hospital, high, grammar, and parochial schools, national and state banks, gas and electric lights, waterworks on the high pressure system, extensive railroad shops, daily, weekly, and monthly periodicals, and, in the suburbs, a national cemetery, where 17,000 union soldiers are buried. Pop. '90, 13,373.

VICKSBURG, SIEGE OF. In the early months of 1863, to capture Vicksburg, the last remaining fortress of the confederates on the Mississippi, and thus to re-open this great river, in its entire length, for all national purposes, was an enterprise scarcely less difficult than important. Hence the concentration, for many months, of naval and military forces to subdue this stronghold. The unsuccessful attempts to reduce the fortifications by bombardments from the iron-clads in the river, and to change the river channel, leaving the city far inland, compelled the conviction that Vicksburg could be captured only by land forces approaching from the rear. Supported by this change in public opinion, Gen. Grant moved down the w. bank, and crossed the river at Bruinsburg, April 30. Following his own plan, he first advanced upon Jackson, where the confederate armies were concentrating under Gen. Johnston. Quickly dispersing these gathering forces, May 14, he destroyed the centring railroads, and left the confederates no means of reorganization. Returning then to his original purpose, Gen. Grant invested Vicksburg so closely that there was no escape, and cannonaded the fortification and the town so fiercely and incessantly that endurance was impossible. The garrison and the people were driven to the last extreme of suffering when this terrific day-and-night siege of six weeks was terminated by a complete surrender, on the same day that witnessed the equally memorable and hard-fought three-days' battle of Gettysburg—July 4, 1863. The union loss was reckoned at 10,000; the confederate loss at about the same, besides the surrender of over 31,000 men and 172 cannon.

VICO, GIAMBATTISTA (or GIOVANNI BATTISTA), a jurist, philosopher, and critic, was born at Naples, 1668, spent the whole of his life in that city, and died there in 1744. He was the son of a small book-seller. He was educated by the Jesuits, and afterward studied for the bar. Weak health preventing him from following his profession, he became tutor in jurisprudence to a nephew of the bishop of Ischia; and after filling this position for nine years, he obtained the chair of rhetoric in the university of Naples. This office was poorly paid; but though much distinguished by persons of the highest position, Vico did not succeed in getting a better one until the accession of the Bourbons, 1735, when he was appointed historiographer to the king of Naples. As he married early, and had a large family, his life was passed in great poverty, and it was, moreover, imbittered by family troubles, and by constant ill-health The great work which has made his name illustrious, the *Scienza Nuova*, first appeared in 1725; but it was completely recast in a subsequent edition, published in 1730, with the effect of making it more imposing as a system, at the expense of a great loss of clearness. A third edition, in which the work was considerably enlarged, was published in 1745, shortly after the author's death. In the *Scienza Nuova*, Vico brought together, and attempted to fuse into a system, opinions which he had previously advanced in a somewhat numerous series of separate treatises. The work was long in arriving at its proper place in European literature, which must be in a great measure attributed to its obscure and enigmatical style. Much of the obscurity arises from the use of an uncouth terminology, which the author often leaves unexplained, and (in the case of the later and authoritative editions) from the rigorous application of the deductive method to subjects which do not always admit of it. The *Scienza Nuova* was virtually unknown out of Italy in 1822, when a German translation of it appeared at Leipsic. It was, a few years later, translated into French (with some curtailment) by M. Michelet (*Principes de la Philosophie de l'Histoire, traduits de la "Scienza Nuova" de G. B. Vico;* Paris, 1827); and the author has since that found his proper rank among the most profound of modern thinkers.

The *Scienza Nuova* (*De' Principj della Scienza Nuova d' intorno alla Commune Natura delle Nazioni*) may be described as a *Novum Organum* of politico-historical knowledge. Observing, amid the infinite variety of thoughts and actions, of language and manners,

which the history of nations presents, a concurrence of the same characteristics, in the political changes which peoples the furthest removed from each other in time and place have passed through, an essential similarity of development, Vico proposed to himself the task of distinguishing amid social phenomena the regular from the accidental; of finding out the laws which govern the formation, the growth, and the decay of all societies; in fine, of tracing the outlines of the universal, the ideal history of society—the idea of which he himself believed to have existed from eternity in the mind of God. In doing this, he attempted, by means of historical criticism on the widest basis to illustrate the inter-dependence of all the sciences; to show that the progress of each of them is related to that of all the others, and the progress of all of them dependent upon, while also acting powerfully upon the general condition of society. And while holding that the actual state of every society is the result of a free development of the human faculties, he attempted to give a historical demonstration of the existence of a Divine Providence directing the career of nations, overruling the designs which men propose to themselves; operating, however, not by positive laws, or arbitrary interferences, but by means of methods and expedients which men resort to freely. It has been not inaptly said that the *Scienza Nuova* includes a system of social (as distinguished from natural) theology—a demonstration of God's government of the world, and of the laws in which that government consists. Vico, in these inquiries, accepted from Descartes the individual consciousness as one of the criteria of truth; but he also employed another—the collective consciousness, or the common sense of mankind—the accord of the race, as it may be gathered from history—in a word, authority.

It would be difficult to overrate the ingenuity and originality of many of the inquiries into which Vico was led by the attempt to delineate the ideal history of society; and he has rarely failed to put forward views, rational and probable, compared with those which were accepted among his contemporaries. With a truly admirable insight, he has not seldom hit upon the conclusions to which increased social knowledge and more scientific conceptions have conducted inquirers of later generations. Thus, in clearing the ground for the foundation of his system, he was led to precisely those views about Homer and the authorship of the Homeric poems which are popularly associated with the name of Wolf; and to anticipate the general view of the credibility of early Roman history which was elaborated by Niebuhr.—(See also Comte, the germs of many of whose speculations may be found in Vico). The beginnings of religion, the origin of poetry and language, the commencement of society (which he ascribes to the influence of a common religious belief and worship), the foundation of the privileges of the heroic or aristocratic class, are among the earlier subjects of his speculation. He proceeds to trace the origin of jurisprudence, and to show how its development has been dependent upon social changes; and he afterward deduces from the history of ancient societies, and, in some degree from the history of the governments which sprung out of the ruins of the Roman empire, the laws which govern the progress, the conservation, and the decay of nations. A monarchy, with an equality of civil and political rights as between subjects, was his ideal of good government for advanced societies.

Though he ascribed to religion a paramount influence in forming and in conserving society, and though it was one of his principal objects to demonstrate the divine government of the world, Vico did not escape the suspicion of having written in a spirit of hostility to religion. It was alleged that he had written so obscurely, as he often did, through the fear of incurring ecclesiastical censures. Some critics of another school charged him, with at least equal plausibility, of having striven, both in his particular doctrines and in his consecration of the principle of authority, to satisfy the Roman Catholic church. The cavils made on either side, however, do not seem deserving of much attention; and it is pleasant to know that Vico, though not unconcerned about the accusations made against him, felt in his later years consoled for the many trials and disappointments of his life by the completion of a work, the greatness of which he knew better than any of his contemporaries. In 1818 the marquis deVilla Rosa published a collection of the whole of Vico's works. A second edition appeared in 1835.

VICTOR, Claude Perrin, Duke of Belluno, and Marshal of France, was born, Dec. 7, 1764 at La Marche, in the department of Vosges, and at the age of 17 enlisted as drummer in a regiment of artillery. He received his discharge after eight years of service as a common soldier; but re-enlisted in 1792, and having fortunately attracted the attention of Napoleon by his able conduct at the siege of Toulon, 1793, was promoted, through his influence, at the close of that year. In the Italian campaigns of 1796–97, and 1799–1800, he commanded the vanguard, and aided by the favor of Napoleon, who threw opportunities in his way, displayed great skill and extreme daring on numerous occasions. At Marengo he maintained such an obstinate resistance for eight hours to the overwhelming numbers of the enemy, that the expected re-enforcements had time to arrive, and convert the imminent victory of the Austrians into a crushing defeat. In 1806 he commanded, with distinction, a *corps d'armée* in the Prussian and Russian campaigns, and though captured in 1807 by Schill's partisans, he was exchanged (for Blücher) in time to win on the bloody field of Friedland, the baton of marshal of France, and the title of duke of Belluno. As governor of Berlin, he gained the esteem of the Prussians by his dignity and moderation; and in 1808 he was sent to command

the first corps d'armée in Spain. Here he gained several victories, notably over Blake at Espinosa, and Cuesta at Medellin; but was defeated by Wellington in the obstinate battle of Talavera (q.v.), and again by sir Thomas Graham at Barrosa (q.v.). After a fruitless blockade of Cadiz he was recalled to command the ninth corps d'armée in the Russian campaign of 1812; and though occasionally defeated in his many contests with the Russians his general conduct and success were worthy of his previous high reputation. When the allies, in overwhelming numbers, were closing round France, Victor appeared prominently in the fore-front of the defense, made a valiant stand at the passes of the Vosges, and retook St. Dizier and Brienne at the point of the bayonet; but his neglecting to occupy the bridge of Montereau was a fault which Napoleon could not pass over, and he was deposed in favor of Gérard (q.v.). Notwithstanding this disgrace he persisted in continuing with the army, and his zeal for his country suffered no diminution, as his energetic conduct at subsequent minor combats, and at the battle of Craonne, sufficiently proved. A severe wound which he received at this last battle brought his military career to a close; and had it chanced to be mortal, the character of Victor would have stood out in bold relief on the page of history as an able soldier, a faithful friend and follower, and a sterling patriot. But though not mortal, in a physical sense, it brought death to his hitherto spotless reputation; for the sickening ardor of his professions of loyalty to the Bourbons, and his vile calumniations of the now fallen chief, to whom he wholly owed his rise, displayed the foulest ingratitude. Victor's servile attachment to Louis XVIII., however, gained him a peerage and other honors; but the readiness with which he accepted the presidency of the military commission appointed to try such of his old companions in arms as had deserted to Napoleon during the "hundred days" brought upon him merited obloquy. His subsequent career requires but brief notice. He was minister of war in 1821–23; second in command in the Peninsula in 1823; and was afterward accredited as ambassador to the court of Vienna. The Austrian court refused to receive him unless he laid aside his ducal title; and this question of etiquette attracted so much attention, and gave rise to so much vehement discussion that the good understanding of the two countries was for a time endangered. After this event, Victor took no part in public affairs, and died at Paris, Mar. 1, 1841.

VICTOR-AMADEUS, the name of three sovereigns of the house of Savoy.—Victor-Amadeus I., duke of Savoy, succeeded his father, Charles-Emanuel the great, in 1630, and carried on the war with France; but in 1631 he was forced to surrender Pignerol, La Perouse, Angrone, and Luzerne to France, in exchange for Montferrat and Alba. He paid great attention to the internal improvement of his dominions, and re-established the university of Turin on an extended scale; but the irresistible pressure exercised on him by Richelieu forced him into a war with the Spaniards in Italy; and after routing his opponents at Tornavento (1636) and Montebaldone (1637), he died at Vercelli, Oct. 7, 1637.—Victor-Amadeus II., grandson of the preceding, and one of the most able of princes, was born May 14, 1666, and succeeded his father, Charles-Emmanuel II., in June, 1675. Till 1680 the administration of government was in the hands of his mother, Marie Françoise of Nemours, who, in spite of the pressure of France on one side and Austria on the other, succeeded in preserving a neutral attitude in the quarrels between her two powerful neighbors. In 1684 Victor-Amadeus married Anne-Marie of Orleans, the niece of Louis XIV.; but the overbearing insolence of the "Grand Monarque," who forced him to persecute the Waldenses (q.v.), and arrogantly ordered him to contribute an auxiliary force to the French army and give up the citadel of Turin, roused the ire of the high-spirited young duke, speedily put an end to the good understanding which would naturally have accompanied their intimate relationship, and drove him into a league with Austria and Spain against France. In revenge, a French army under Catinat assailed Victor-Amadeus's dominions, and though he was re-enforced by 4,000 Austrians under his relative, prince Eugene, the allies were completely routed at Staffarda (Aug., 1690), and the victorious Catinat had completed the reduction of Savoy and Nice before the winter of 1691. The duke, aided by considerable re-enforcements from Austria and Spain, gallantly maintained the contest; but a second and more disastrous defeat at Marsaglia (Oct. 4, 1693), where he left 10,000 dead on the field, put almost the whole of Piedmont at the mercy of the French. The war, however, continued; the duke's obstinacy and almost romantic daring balancing Catinat's high military genius; till in the autumn of 1696 a treaty much more favorable to Savoy than to France detached the former from the grand alliance. When the quarrel respecting the Spanish succession (see Succession Wars) broke out, Victor-Amadeus took part with France—an alliance cemented by the marriage of his second daughter, Louisa Gabriele to Philip of Anjou, the new monarch of Spain, as well as by the previous (1697) marriage of his eldest daughter (the mother of Louis XV.) to Louis, duke of Burgundy, Louis XIV.'s grandson—and was appointed commander-in-chief of the combined armies of France and Spain; but though he was aided by the counsels of his old opponent Catinat, the Austrians, under his former ally, prince Eugene, defeated him at Chiari (Nov., 1701), and drove him behind the Oglio. Two years afterward, the successes of Vendome in Italy and Villars in Germany, by bringing more prominently before his imagination the possibility of having the Bourbons for his neighbors on the e. as well as on the w., along with the tempting offers of Austria and Britain, induced him to abandon France and

join the alliance against her. In revenge for what they called the duke's treachery, the French under Vendome overran and devastated Piedmont; but with the recall of their chief, fortune deserted the French, and they were totally routed by the duke and prince Eugene under the walls of Turin, Sept. 7, 1706. The duke, who had some years before retired from this contest, was rewarded by the treaty of Utrecht (1713) with the rest of Montferrat, Val-Sesia, Lomellino, and the island of Sicily, with the title of king; besides being acknowleged as heir to the Spanish throne in case of the failure of the Bourbon dynasty. In 1720 he was made to surrender Sicily to the emperor in exchange for Sardinia. The latter portion of Victor-Amadeus's long reign was wholly free from foreign strife; and his restless energy was employed in improving the system of administration, thoroughly assimilating the new continental acquisitions, in replenishing the treasury, which, in spite of the British subsidy, had been drained by the long contest with France, and in encouraging agriculture and industry, especially the cultivation of mulberry trees and tending of silk-worms. Reforms and improvements were effected in the university of Turin, and several colleges founded. On Sept. 2, 1730, the king abdicated; but attempting, in the following year, to resume the regal dignity and functions, he was arrested and imprisoned. He died at the château of Moncalieri, near Turin, Oct. 31, 1732.—VICTOR-AMADEUS III., grandson of the preceding, succeeded his father Charles-Emmanuel III. in 1773. His reign was full of misfortune and disaster, and was brought to a close by his death in 1796 after the compulsory cession of Savoy and Nice to the French republic.

VICTOR-EMMANUEL I. (Ital. *Vittore-Emanuele*), King of Sardinia, the second son of Victor-Amadeus III., was born July 24, 1759, and till his accession bore the title of duke of Aosta. He was one of the most determined adversaries of the French revolution; and on the outbreak of war in 1792, he was chosen to command the Sardinian army, repulsed the French at Gillette, and forced his way to the mouth of the Var, but was ultimately compelled to seek shelter among the Alps. He opposed himself strongly to the conclusion of peace with France in 1796; and from this time lived in southern Italy, and afterward at Cagliari, whence he did not return to Turin till 1814. He had assumed the royal title on his elder brother's abdication in 1802; and the treaty of Paris restored to him Piedmont, Nice, and the half of Savoy in 1814; the treaty of 1815 added the remainder of Savoy, while the congress of Vienna presented him with the duchy of Genoa —so that the little kingdom had profited territorially by its troubles. But the loyal delight of the Savoyards and Piedmontese at the return of their legitimate ruler was speedily quenched by the first acts of his administration. The French institutions to which they had been long enough accustomed to feel their immense superiority over the system they had supplanted, were abolished, and the old absolutism gradually restored. This change, which was no doubt to a certain extent effected by way of destroying all trace of French domination, by depriving the people of various important privileges and amenities, restoring old and hated abuses, and increasing taxation, excited wide discontent, which was heightened by the odious religious persecutions of the Vaudois and the Jews; secret societies were formed, and on Mar. 10, 1821, a revolution broke out. The army proclaimed the constitution promulgated by the Spanish Cortes in 1812; and the king, rather than take the oath to it, resigned in favor of his brother, Charles Felix, Mar. 23, 1821. He died at Moncalieri, near Turin, Jan. 10, 1824.

VICTOR-EMMANUEL II., the first king of a united Italy, was the son of Charles-Albert (q.v.) of Sardinia, and was born Mar. 14, 1820. He was a pupil of the Jesuits, but under his father's superintendence received an excellent education; and, being heir to the throne, he commanded, in accordance with an old custom of his house, the brigade of Savoy in the campaign of 1848–1849, and displayed great gallantry at Goito and Novara. On the evening of the latter battle, his father, seeing the hopelessness of the struggle, and unwilling to bow to the onerous conditions offered by Radetsky, abdicated in favor of Victor-Emmanuel, who, being the husband of the archduchess Adelaide (the cousin of the Austrian emperor) and uncommitted to the views of the Italian ultra-democrats, might hope to obtain more favorable terms from the victor. Victor-Emmanuel thus ascended the throne of Sardinia, Mar. 23, 1849, and restrained effectually, for a time, the enthusiasm of the more ardent among the national party, though, on the other hand, he maintained, with the utmost fidelity, the provisions of the liberal constitution granted by his father. He made a happy choice of ministers in such men as Cavour, D'Azeglio, etc., whose policy it was to increase the strength and importance of the country by improved administration, rigid economy in the finances, care of the army, and encouragement to trade by the conclusion of commercial treaties with foreign nations. They saw too clearly that, despite the intense and almost unanimous desire for unity throughout Italy, a contest single-handed with Austria was utterly hopeless, and preferred, till a more convenient season, to seem to renounce all idea of any such project. The property of the state was sold, and various measures calculated to greatly diminish the privileges, and restrict within moderate limits the inordinate influence of the clergy, adopted—changes which brought upon the king the thunders of the Vatican; but Victor-Emmanuel, nothing daunted, protested by a vigorous "memorandum," and more obstinately asserted and maintained his independence of the papacy. The revolt at Genoa was sternly suppressed; but the king and his ministers were, in secret, by no means displeased to see that the feeling of nation-

ality was still vigorous; for, following the traditional policy of the house of Savoy, he was only biding his time to "descend with the valley of the Po," and swallow "another leaf of the artichoke." With the view of improving his position in Europe, and gaining a place at its council-board, he sent an army of 17,000 men, under La Marmora, to take part in the Crimean war on the side of Turkey; and visited (1855) in person the courts of Paris and London, being received by French and English with great enthusiasm. After the peace of Paris (1856) he entered into a closer alliance with France, gave his elder daughter Clotilde in marriage (Jan. 30, 1859) to prince Napoleon, and, backed by the French arms, provoked a war with Austria. The campaign was brief but decisive—the Austrians were routed in every battle, and the Italians were hailing with exultation the near approach to fulfillment of their long-cherished dreams of unity, when the suddenly concluded peace between France and Austria at Villa-Franca dashed their hopes to the ground. The Milanese (minus the fortresses of Mantua and Peschiera) only was to the Sardinian monarchy, and for this the king ceded Nice and Savoy (the cradle of his race) to France as the price of its alliance. But the people of central Italy refused indignantly the offer of prince Napoleon as their sovereign; and Tuscany, Modena, Parma, and the Romagna, renouncing their allegiance to their respective sovereigns, voted for annexation to Sardinia, and were formally adopted by Victor-Emmanuel, as his subjects. This was a greater advance toward the unification of Italy than the French emperor wished, and accordingly, Victor-Emmanuel, who was still dependent on his ally for safety, though secretly favorable to Garibaldi's expedition to Sicily, disavowed all knowledge of this project, and after the island was conquered without a blow being struck by a single Sardinian soldier, forbade the "Italian liberator" to pass over to the continent; yet he subsequently, with the consent of Napoleon III., sent an army to aid Garibaldi in conquering Naples, and formally accepted the sovereignty of the Two Sicilies. But in 1862 Garibaldi, thinking that the conquest of Rome in the same way would be equally acceptable to his sovereign, returned to Sicily, raised an army of volunteers, and was rapidly advancing on the ancient capital, when Victor-Emmanuel, forced by France, put an end to the expedition by capturing Garibaldi and his army at Aspromonte. Though proclaimed by the senate and house of deputies *king of Italy* in Feb. 1861, Victor-Emmanuel prudently postponed all attempts to annex Rome and Venice; and directed his attention to the internal affairs of his kingdom, which was much distracted by the intrigues of the sovereigns whom he had supplanted. At length, in the quarrel between Prussia and Austria for supremacy in Germany, appeared his opportunity; and an offensive and defensive alliance with Prussia was followed by an Italian invasion of Venetia (June, 1866). The Italians were defeated in the bloody battle of Custozza; but the disasters which befell Austria in her simultaneous contest with Prussia, forced the Austrian empire ultimately to surrender Venetia. In Aug., 1870, after the outbreak of the war between France and Germany, the last detachment of the French garrison which had occupied Rome since 1849 was withdrawn; the imperial city, finally united to the kingdom, became the capital of Italy and the seat of Victor-Emmanuel's court. The last years of Victor-Emmanuel's life were uneventful. He died after a short illness, Jan. 9, 1878, and was succeeded by his son Humbert.

VICTORIA, although one of the youngest, and, in point of area, the smallest of the colonies of the Australasian group, is already the most important. In extent of commerce, indeed, it takes precedence of all British colonies—India alone excepted. The extreme modernness, so to say, of the Australian colonial picture is one of its most striking features, for it belongs emphatically to the present generation. Men who are still in middle life may recollect when the Port Phillip settlement—the name first given to Victoria—had no existence; and those are not yet very old who may remember when even the geographical outline of Australia was incomplete, and when the great harbor of Port Phillip, now the busy scene of the world's commerce, was undiscovered and unheard of.

Geographical Position and Extent.—Victoria comprises the s.e. corner of Australia, at that part where its territory projects furthest into cool southern latitudes. Wilson's promontory, to the s.e., the most southerly headland, just passes the 39° of s. lat.; while the most northern point, which is at the opposite or n.w. extreme, is in s. lat. 34°. The long. comprises 9°—between 141° and 156° e. of Greenwich. To the w. is the colony of South Australia, separated by the 141° of e. long.; to the n. is New South Wales, separated by the line of the Murray river eastward from 141° e. long. to its source, and thence by a straight line s.e. to cape Howe; and from cape Howe to South Australia, again, the colony is bounded on the s. by Bass's strait. The extreme length is e. and w., and is about 480 m., by an extreme width, n. and s., of 250 miles. But a remarkable indentation of both the n. and s. boundary opposite each other, about the middle of the colony, reduces the breadth between the head of the Port Philip inlet and the Murray to only 120 miles. The superficial area is 56,245,760 acres, or 87,884 sq. miles.

Physical Aspect.—Although Victoria may be called mountainous, as compared with the general flatness of Australia, it has much of the quiet and peculiar scenery characteristic of that division of the world. Vast naked plains are deviously traversed by broad and deep river-channels, which are mostly, however, mere chains of ponds, if not altogether dry, excepting in winter and spring, or after heavy showers. Overspread, in

cool and moist seasons, with brilliant verdure, the drought and heat of summer quickly convert the grass into a natural hay, which, in the scarcity of sustenance from its ceasing to grow in that condition, is eaten off to the very roots by the sheep and cattle, leaving the surface a bare and blackened mass. The "open forest" is another and very pleasing variety of scenery characteristic of Australia, and largely prevalent in Victoria. It distinguishes the gently undulating country of the better soils, whose surface is overspread by large trees, chiefly of the red gum (*eucalyptus*) and silver wattle (*acacia*). The trees being widely apart and of spare foliage, and the surface free from underwood, there is commonly a good growth of grass, the whole presenting a charming and park-like aspect, although felt to be somewhat tame and monotonous, especially under the great defect of most Australian landscapes, the general want of water. Mountain and forest prevail most in the e. division, where the Australian Alps of Gipps's land, the loftiest of Australian chains, culminate in peaks ranging from 1000 to 7,000 ft. above the sea. The w. district, on the other hand, is chiefly remarkable for its numerous isolated hills of volcanic origin, some of them with craters still perfect, which probably have not, in a geological sense, been very long at rest. To this extensive volcanic system Victoria owes the large proportion of its good arable land, as compared with the light sandstone and granite soils that prevail elsewhere in Australia. The chief rivers, besides the Murray and its branches (elsewhere treated of), are the Snowy river, the Tambo, the Mitchell, the Macallister; and the La Trobe—all of Gipps's land; the Yarra-Yarra, the Goulburn, the Loddon, the Wimmera, the Avoca, the Wannon, the Ovens, the Hopkins, and the Glenelg, of which rivers, however, several are not perennial streams. The Australian fauna is very remarkable; notably the kangaroo or pouched family, and the emu or great wingless bird. There are besides the *echidna* and *platypus*, of quite a different family, and even more singular in structure, especially the last, as indicated by its other name of *ornithorhynchus paradoxus*. The dingo, or native dog, is remarkable as a non-marsupial exception, on which account it has been regarded as an introduction by human agency. But several years ago Prof. McCoy of Melbourne met with its fossil remains associated with those of extinct animals, and in deposits that, although recent, geologically speaking, are in other respects so remote as to establish this animal's indigenous claim.

Climate.—This is on the whole healthful and agreeable, but subject to frequent and sudden change in condition and temperature. The average temperature of the year is between 57° and 59°, or about 9° above that of London, and 7° above that of New York. The common summer-heat is from 65° to 80°, with an occasional advance to 90° and even to from 100° to 108°, during hot winds and a dry season. The winter range is mostly from 45° to 60°. Ice occurs in the midwinter of July, but it rarely, except on elevated ground, survives the noonday sun. Every few years an unusually severe season will cover the higher levels, and even the country generally, with snow, to recall to the colonists the familiar scenes of ancestral homes. The cold of winter is keenly felt, and household fires are not uncommonly indulged in for even six months of the year, especially in the morning and evening.

Civil and Political Divisions.—Victoria is divided into four districts and 37 counties, the principal counties being Bourke, Talbot, and Grant. Prior to 1848 there were but three counties, the still existing Bourke, Grant, and Normanby, laid out in 1837, along with the sites of several chief towns, when the infant settlement, then but two years old, was officially taken charge of by the New South Wales government, within whose jurisdiction the territory was then comprised. One chief object of the counties was to distinguish by certain special regulations the more accessible and valuable of the colonial lands, leaving the remainder (the districts) to pastoral or squatting uses. But the subsequent discovery of the gold-fields in 1851 interfered with this arrangement, as the new condition created towns and markets indiscriminately in county and district. Squatting is still an important colonial vocation, second only to gold-mining, and still pursued over most of the colonial area. The electoral districts, in general, coincide (but not always) with county and municipal divisions. This is the case for the assembly, but for the council or upper house there is (since 1881) a division of the colony into fourteen districts. For the purpose of local self-government there were, in 1894, besides counties, 58 urban districts and 145 rural municipalities. The former are towns, boroughs, and cities; and the latter are called shires.

History.—The distinction of first settling Victoria is due to the Messrs. Henty of Launceston, Tasmania, who occupied the s.w. part at Portland bay with some flocks of sheep in 1834. But the settlement that mainly influenced the future was that of the following year upon the shores of Port Phillip. This enterprise also was from Launceston, first in May and June by a small party under Batman, which occupied Indented Head, on the w. side, 15 m. inside the harbor; and again in August following by another party sent forth by Fawkner, he himself having been detained a short while longer by sickness. This last party passed on to the head of Port Phillip, ascended the Yarra, and settled upon the site of the present capital, Melbourne. The story of the subsequent progress is marvelous even in an age of marvels as to colonies. When the gold mines were discovered, the settlement, after 16 years' existence, had a colonial population of 80,000, of whom nearly one-third were in the capital. Thenceforth for several years the advance has scarcely been paralleled. The imports, exports, and the public revenue

increased tenfold. In 1856 Melbourne had become a city of great wealth and commerce, containing 100,000 inhabitants, while the colony comprised above 400,000. Although the race has since been at a more leisurely speed, Melbourne has continued to advance, and in 1890 the pop. had increased to 445,220. See MELBOURNE. Some interior towns besides, are rising to importance, in particular Ballarat. Geelong, with 21,380 of population, finely situated on the western arm of Port Philip, was second only to Melbourne; but is now surpassed by Ballarat (with 42,547) and Sandhurst (with 36,630), the two principal gold-field towns of Victoria. The pop. of Victoria in 1890 was 1,131,247.

Victoria, while a part of New South Wales, was termed the Southern or Port Philip district of that colony. As early as 1840 an agitation for separation, and a government independent of that of New South Wales, began, and was ended successfully in 1851, when the new colony received the name it now bears. The title of lieut.governor was then given to the queen's representative in this colony as well as in others adjacent, the gov.general being in New South Wales. But the rising importance of Victoria led to this distinction being discontinued some years afterward. This importance indeed expedited, to these colonies, their concession of self-government, which was inaugurated in the years 1854–56, with very lively demonstrations on the part of the colonists, who have since shown no want of interest or earnestness in the charge of their own affairs. During this last brief term, although the progress, in point of population, owing to diminished immigration, has been unimportant, there has been a very marked advance in the improvement of the colony generally, and of the arts and industries and amenities of social and commercial life. At the great international exhibition of 1862, Victoria stood at the head of the entire colonial department; and in less than twenty years this enterprising colony held an international exhibition on a large scale in its own capital (1880–81), which was visited by over 1,000,000 people.

Population, Colonists.—The population of Victoria, in common with that of the other members of the group, is in the main English, in the wider sense of the word. According to the census of 1891, 97 per cent. of the population were British subjects by birth, and of these the majority were native-born. Next in numerical strength to the native Victorians were persons born in the British Isles or in the other Australian colonies. The total population in 1891 was 1,140,405, showing an annual increase of 3.22 per cent. since 1881. The discovery of the gold fields brought in a large number of Chinese, who in 1891, however, numbered only 9377. In that year there were only 565 aborigines in the colony. The various religious denominations of the United kingdom contribute somewhat ratably their quota to the colonial population. The census of 1891 gave the numbers in connection with the various denominations as follows: Episcopalians, 417,182; Presbyterians, 167,027; Methodists, 158,040; other Protestants, 94,608; Roman Catholics, 248,591; Jews, 6459; Buddhists, Confusians, etc., 6746. At the time of this census about 75 per cent. of the population were Protestants and 22 per cent. Roman Catholics. Mission work is actively carried on.

Natives.—By the census of 1891, the aborigines were found to number 565, consisting of 325 males and 240 females. The number when the settlement began is usually stated to have been 6000, although probably much larger, seeing that Tasmania, only one-fourth of the extent, and with a climate less genial to savage life, is supposed to have contained 5000. But that is a point about which we can now only conjecture. The native is fast dying out from the colonized area. The progress of colonization has been utter destruction to his prospects. Philanthropic and Christian efforts on his behalf have not been absolutely barren. Mission stations in Gipp's Land, conducted by the Church of England and the Presbyterian church, have diffused the influences of civilization and religion to a considerable proportion of the survivors. These missions are under the immediate supervision of Moravians, and aim a little at the culture and preservation of the race, not without some evidences of success.

Commerce.—The two staple articles of export from the colony are wool and gold. The exportation of the former in the year 1894 was valued at £5,151,153; of the latter, at £3,750,737, in both cases an increase as compared with the previous year. After the gold discoveries in 1851 there came an extraordinary commercial development. For that year the imports had been £1,056,437, and the exports, £1,422,909. In 1854 the amounts were respectively £17,659,051 and £11,775,204. But this sudden extension—at least as regarded imports—was not maintained, because it was due, in part, to a temporary extravagance, and partly because the colony has since then been successfully organizing its industry, so as to produce cheaply, and partly by the introduction of a heavy protective tariff. For 1895 the imports were £12,472,344; the exports, £14,547,732. In 1895 the shipping entries amounted to 2,181,539 tons; clearances, 2,167,147 tons, a large number of which were British. The annual production of gold in Victoria has greatly decreased since 1856. In that year the output was valued at about £12,000,000, while in 1895 it was only £2,960,344, but the latter figure was somewhat in excess of the figures for each of the four preceding years. Between 1851 and 1895 the amount of gold mined in the province is estimated at 60,186,321 ounces, valued at £240,745,248. Between 1891 and 1895 the value of the exports of wool fell from £7,165,092 to £5,151,153. Beside these staple articles Victoria exports grain, live-stock, and leather in considerable quantities. The imports consist largely of manufactured articles. The British Isles and the other Australian colonies have the largest share of the trade. There is a tariff of about 15% on imported goods.

The chief colonial vocations are squatting or pastoral pursuits, agriculture, and latterly, gold-mining. The first-mentioned was the earliest that rose to importance; but the last has rapidly outrivaled every other. Agriculture, at first dwarfed by the success and influence of squatting, and for a time impeded afresh by the social upturning during the first years of gold-mining, is now, however, rapidly extending, and is improving, socially as well as physically, the aspect of the country.

Squatting.—This colonial term has long since passed from its originally semi-savage and outcast associations, to represent in Australia a rural aristocracy. The squatter, using the country just as he found it, placed upon it his live-stock, which lived and throve on the natural herbage. This ready adaptation of the surface, with comparatively little of preliminary outlay, is the chief cause of Australia's rapid progress. At first, the pastoral "stations," or "runs," as they were then very appropriately called, were uninclosed areas, parceled out to a small number with a very bountiful hand, and at a nominal rent or occupation license-fee. Now, however, these areas have been much subdivided, and much has been done in inclosing the runs with stout fencing.

Agriculture.—Comparatively little was accomplished in this branch for 25 years, until 1860, when the government began to increase the facilities for acquiring and cultivating the public lands. In 1861 there were but 180,000 acres under the plow; in 1896 the extent of land under the principal crops was 2,864,000 acres. The dry climate of Southern Australia seems favorable to the quality of wheat; and the Victorian samples at the great exhibition of 1862 ranked among the very best. In 1895–6 about 30,700 acres were under vines.

The following table taken from the report of the U. S. consul at Melbourne dated December 14th, 1896, gives the acreage under wheat, the average yield in bushels, and the average number of bushels per acre between 1889 and 1897.

Year.	Area.	Yield.	Average.
	Acres.	Bushels.	Bushels.
1889-90	1,200,000	11,912,500	9.92
1890-91	1,209,000	14,250,000	11.78
1891-92	1,247,000	13,387,500	10.73
1892-93	1,375,000	16,471,000	11.98
1893-94	1,395,000	13,985,000	10.02
1894-95	1,457,000	13,766,500	9.44
1895-96	1,486,000	7,675,000	5.16
1896-97	1,493,000	6,904,000	4.62

From this it will appear that the annual production of wheat has decreased and that the production per acre has also decreased. One cause of the decrease was the lack of rain and where irrigation was resorted to, good crops were produced, even in the dry seasons. Among the other cereals raised in the country were barley, maize, oats, rye, peas and beans. Next to wheat the most important cereal is oats. In 1895–6 there were 2,880,045 bushels produced, not much more than half as much as in the previous year. The oat crops also have suffered from drought and it has been necessary in many cases to resort to irrigation. Barley also showed a large falling off, but the production of maize increased considerably over the yield of 1894–5.

Manufactures.—In 1895 there were in Victoria 2675 manufacturing establishments, employing 41,273 hands. The value of the lands, machinery, etc., was estimated at £12,896,800. The manufactures are almost exclusively for the home market. A branch of the royal mint was opened in 1872.

Gold-Mining.—This may now be termed one of the skilled labors of the colony; but it is not by any means, on an average, among the most remunerative. Of the two great branches of mining — viz. (1), the crushing of the auriferous rock for the washing out of the gold, and (2), the washing from the débris or "drifts" which nature has already pounded down—the latter, as a simpler process, was at first the most general, but lately the other has been increasingly followed.

Railways.—The system is more extensive and complete than in any of the other southern colonies. At the end of 1895 there were 3103 m. of railway open for traffic. The railways are government property.

Finances.—The public revenue is derived mainly from these sources—customs dues, railways, posts and telegraphs, and public works. The total revenue of Victoria for the year 1894–5 was £6,712,152. The chief items were — customs, £1,809,140; crown lands, £473,580; railways £2,583,442; post and telegraphs, £509,721. The revenue for the year ending June 30, 1884, was £5,934,240. The income is generally ample for all expenses. The outstanding public debt amounted in 1896 to £46,886,211, by far the largest proportion of which was incurred in the construction of railways, all of which now belong to the state. Taxation, according to the revenue accounts, amounts to about £2.6s per head.

Political Institutions.—The self-government conceded to Victoria and the adjacent colonies gives them a responsible system similar to England. The governor represents the sovereign, who appoints him; and he governs by ministries, who are of the crown's, that is, of the governor's nomination, but who must possess the confidence of parliament. There are two houses of legislation, both in Victoria being elective—the council or upper house by a high and special qualification; the assembly by manhood suffrage, without any qualification for members. Elections are by secret ballot. The term of the governorship is usually seven years. The present salary of the office in Victoria is £7,000 a year; and in the expensive times more immediately succeeding the gold discoveries, it was £15,000. The salary is paid wholly by the colony; but by a recent imperial act, the home government allows moderate pensions to retired governors, according to the term of service. In 1891 Victoria sent delegates to the Australian convention held at Sydney, to frame a federal constitution. See IMPERIAL FEDERATION.

Religion.—The divergence of the self-governed colonies from home example is perhaps most striking in two very important subjects—religion and education. In religion, as in politics, the tendencies are toward a complete equality, and therefore opposed to the privileges involved in church establishments. In this respect, change of scene, and equality and independence of condition, sensibly weaken the strength of tradition and usage as exhibited in the senior country. All religious bodies, therefore, stand alike before the civil power, none having any coercive jurisdiction except such as its own members voluntarily impose upon themselves, either by their own rules, or by a special act solicited from the colonial legislature. In Victoria, until 1875, there was a yearly donation of £50,000 from the public revenue to the support of religion. It was distributed ratably among the sects, Unitarians and Jews included, and was "scheduled"—i.e., not subject to yearly vote—under the constitution act. This system, introduced into Australia as a substitution for the preceding church of England supremacy, terminated in 1875. Lately, the public feeling had tended to a disapproval of the system of indiscriminate support to religion, and some of the smaller bodies had altogether rejected it. The state aid was therefore abolished in some of the colonies. In Victoria, the assembly had repeatedly passed an abolition act, which, however, the council negatived. Ultimately, a bill passed both houses, whereby the grant in aid to religion wholly ceased in 1875.

Education.—The energy displayed on this subject by the popular administrations of the self-governed colonies, and the tenacious persistence with which they encounter the problem of the education of the whole people, are among the best results presented to us by these young offshoots. Under the preliminary "imperial régime" of colonial public life, the comparatively neglected field as to education is taken up, and with creditable zeal, by the various clergy, who institute, of course, the denominational system. But essential difficulties stand in the way of the successful importation of a general education under this system. A national system, to compete with the previously established denominational, had been introduced into New South Wales and Victoria with the advent of the partially representative legislatures that for about twelve years preceded the present self-government. National and denominational, each conducted by a separate board of management, were alike aided by the state. The institution of a partially national system, and of a single board, was carried in the Victorian legislature in 1862. That system was in effect, that all state-assisted schools must be open to the children of all religious bodies, and that four hours daily of secular teaching be imparted to every pupil. This arrangement, on experiment, was unsuccessful. Schools still remained in connection with the several denominations; denominational school committees controlled the election of teachers, who were also permitted to impart religious instruction where desired. As a result, schools were unnecessarily multiplied in some localities, and the money of the state was wasted in their support. After various attempts to establish a system of state schools unconnected with any denomination—attempts which several of the religious bodies combined to defeat—the Victorian government at last succeeded in overcoming all difficulties, and a bill passed both houses of the legislature, which completely establishes a national, as opposed to a denominational system of education. Education is secular, and compulsory for children between the ages of six and thirteen years; but secondary education is wholly under the control of private persons or of proprietary bodies usually connected with a religious denomination. There are numerous technical schools under the management of the department of education, several schools of mines, art schools, and schools for workingmen. There are public libraries or mechanics' institutes in the principal towns, and the library at Melbourne is especially large and fine. The percentage of illiteracy is small. In 1891, 95¾ per cent. of the population of 15 years of age or more could read and write. The total number of state schools in Victoria was (1895), 1922, with an enrollment of 232,052; 867 private schools with 38,062 scholars; besides grammar schools, various colleges, and the Melbourne university. Victoria has a university at Melbourne with three affiliated colleges, viz., Trinity College (Church of England), Ormond College (Presbyterian), and Queen's College (Wesleyan). The Ballarat School of Mines is also connected with the university. The university was opened in 1855 and has a considerable endowment. It was chartered in 1859 and confers degrees in all departments of university education except divinity. In 1895 there were 693 students in attendance.

Remarks to Emigrants.—Intending emigrants should understand that Victoria is no longer a new and scantily peopled territory, with all the superabundant employment and means of subsistence that are readily found now-a-days on such a scene by help of the arts and implements of an advanced civilization. There are now in the colony the advantages of a settled society, having much of the amenities of home-life; but, on the other hand, the colonial vocations are tolerably filled up by the increasing population, so that the unsuitable or the inexperienced have hardly any better chance out there than at home. It is owing to considerations of this kind that the system of free or assisted emigration—a system still maintained to a limited extent by the colony—has been latterly conducted upon very strict principles; the object being, that persons unsuitable to the colony may, as far as possible, be prevented from going there. The system of granting free passages has, on the whole, been recently discouraged by the legislature and government of Victoria, where the influx of the home poor is dreaded. Both free and assisted emigration is for the present wholly suspended. Laborers, mechanics, and artisans used to obtain assisted passages by what are known as passage warrants, issued to residents in the colony, on making the following payments to the colonial government: For each male under 15 years of age, £4; between 15 and 40, £8; above 40, £9. for each female under 15, £3; between 15 and 40, £4; above 40, £5. The warrants available for nine months after issue, had to be forwarded to the emigration agent of the Victorian government. Steady-going workingmen, agricultural and farm laborers in particular, are in request, and are sure to do well. Self-reliance, steadiness, and good conduct are essential requisites to success in all the colonies; with these, no workingman of the special classes referred to can fail to better his position, and add to the comforts and happiness of life. There is special encouragement to female emigration. As a general rule in Victoria at present, wages and remuneration generally are one-third or one-fourth higher than in Great Britain; while the chief requirements of life are, one with another, at about the same price as they are there. House-rent is rather higher, while butcher-meat is cheaper, and other necessaries about equal. The climate is, as a whole, highly enjoyable, with its bright skies and sunshine; but to workingmen, six months of the year (from the middle of October to the middle of April) will be found somewhat oppressive for great physical toil—a consideration no doubt present to the working-classes of the colony in connection with their successful introduction of an eight hours' labor system.

VICTORIA, a co. in s. Texas, having Lavaca bay for its s.e. boundary; drained by the Guadeloupe river; 850 sq. m.; pop. '90, 8737, chiefly of American birth, with colored. Co. seat, Victoria.

VICTORIA, a co. in n. New Brunswick, having the St. John river for its w. boundary, separating it from Maine; and Moose mountain in the s.w.; 3490 sq. m.; pop. '91, 18,217. Co. seat, Grand Falls.

VICTORIA, a co. of e. Nova Scotia, on the island of Cape Breton, having the Atlantic ocean for its e. boundary; 1200 sq. m.; pop. '91, 14,432. Co. seat, Baddeck.

VICTORIA, a co. in n.w. Ontario, drained by large lakes; 1305 sq. m.; pop. '91, 37,204. Co. seat, Lindsay.

VICTORIA, city, capital of the province of British Columbia, Canada, and co. seat of the Victoria district; at the s.e. extremity of Vancouver island; on the strait of San Juan de Fuca, and the Esquimalt and Nanaimo railroad; 84 miles s.w. of Vancouver. It was originally a trading post of the Hudson bay company; was platted for a town in 1852, and incorporated as a city in 1862; and has since become the most important Canadian city on the Pacific. It has extensive and rapidly growing commercial interests. Esquimalt, 3 miles distant and practically a suburb, is the seat of a new British naval station, with fortifications, dock yard, arsenal, royal naval hospital, and naval cemetery. Victoria has several hospitals, central, high, and ward schools, Anglican college for women, St. Ann's convent, public library, electric lights, and about 15 churches. It has regular steamship communication with San Francisco, Alaska, New Westminster and other points on the n.w. coast. Pop. '91, 16,841.

VICTORIA, a genus of plants of the natural order *nymphæaceæ*, resembling the common water-lily, but most nearly allied to the genus *euryäle*, and distinguished from it particularly by the deciduous tips of the calyx, and the sterility of the innermost stamens. Only one species is yet known, *Victoria regia*. This is said to have been first observed by Hänke, about 1801, and afterward to have been seen by Bonpland, D'Orbigny, and others. It was first described in 1832 by Pöppig, who observed it in the river Amazon; and it has since been found by Schomburgk and others in many rivers of the n.e. of South America. Its leaves are orbicular, float upon the water, and attain a diameter of 5 to 6 ft.; have the margin turned up, and about two inches high; are of a purplish color on the under side, and there exhibit a sort of wicker-work of very prominent veins, furnished with prickles. The flowers rise among the leaves upon prickly stalks. They are more than a foot in diameter, white, internally rose-colored, and are very fragrant. The fruit is a capsule, almost globose, with a depression on the top, about half the size of a man's head, fleshy within, and divided into numerous cells, full of round farinaceous seeds, which are an agreeable article of food. The plant is therefore called *maïs del agua*, or water maize, in some parts of South America. To the cultivation of this plant, special hot-houses have been devoted in some places in the

United States and in Europe. It has been introduced into India from seeds produced in England. See illus., FLOWERS, vol. VI.

VICTORIA I., Queen of the United Kingdom of Great Britain and Ireland, daughter and only child of Edward, duke of Kent, 4th son of George III., was born at Kensington palace, May 24, 1819. Her mother, Victoria Mary Louisa, was 4th daughter of Francis, duke of Saxe-Coburg Saalfeld, sister of Leopold, the late king of the Belgians; and married first to the prince of Leiningen, deceased in 1814; on July 11, 1818, she married at Kew, the duke of Kent. The duke died Jan. 23, 1820, leaving his widow in charge of an infant daughter only eight months old, who had been baptized with the names of Alexandrina Victoria. The duchess of Kent fulfilled the important duties which devolved upon her with more than maternal solicitude, and with admirable care and prudence. The infant princess, as she grew up, was taught to seek health by exercise and temperance, to acquire fearlessness even from her amusements, such as riding and sailing, and to practice a wise economy united to a discriminating charity. After a few years the duchess of Northumberland was associated with her mother in her nurture and education. The princess Victoria became accomplished in music, drawing, and the continental languages; and acquired a knowledge of some of the sciences, particularly botany. Her father having belonged to the whigs, her political education was naturally derived from the members of that party; and to viscount Melbourne (q.v.) belongs the credit of having thoroughly instructed her in the principles of the British constitution. She ascended the throne of the United Kingdom on the demise of her uncle, William IV. (q.v.), June 20, 1837; her uncle, the duke of Cumberland becoming king of Hanover in virtue of the law which excludes females from that throne. By this event, the connection which had lasted for 123 years between the crowns of England and Hanover was terminated. Victoria was proclaimed, June 21, 1837, and crowned at Westminster, June 28, 1838. She found on her accession viscount Melbourne at the head of the government; and during his premiership and with the cordial assent of her subjects, the young queen was married at St. James's palace (Feb. 10, 1840) to prince Albert (q.v.), prince of Saxe-Coburg and Gotha, and second son of the then reigning duke. Her majesty has had issue—four sons and five daughters: the princess royal, Victoria, b. Nov. 21, 1840, married Jan. 25, 1858, to Frederick William, who in 1888 became Frederick III., emperor of Germany, of brief reign; Albert Edward, prince of Wales, heir-apparent to the throne of the United Kingdom, b. Nov. 9, 1841, married Mar. 10, 1863, princess Alexandra Caroline, eldest daughter of Christian IX., king of Denmark; princess Alice, b. April 25, 1843, married July 1, 1862, prince Frederick William of Hesse (d. 1878); prince Alfred, b. Aug. 6, 1844, created duke of Edinburgh, 1866, married Jan. 23, 1874, Marie, only daughter of the emperor of Russia; princess Helena, b. May 25, 1846, married in 1866 to prince Christian of Denmark; princess Louisa, b. Mar. 18, 1848, married in 1871 to the marquis of Lorne; prince Arthur, b. May 1, 1850, created duke of Connaught, 1874, married in 1879 princess Louise Marguerite of Prussia; prince Leopold, b. April 7, 1853, was created duke of Albany, 1881, and married to princess Helena of Waldeck in 1882 (d. 1884); princess Beatrice, b. April 14, 1857, married, 1885, prince Henry of Battenberg.

For the changes of administration in this reign, see the articles GREAT BRITAIN, MELBOURNE, PEEL, RUSSELL, DERBY, ABERDEEN, PALMERSTON, GLADSTONE, DISRAELI. The legislative measures of greatest importance were the establishment (1840) of the penny-postage (see POST-OFFICE); the amendment of the poor-laws (q.v.) in Scotland (1845) and Ireland (1847); the abolition (1846) of the corn laws (q.v.), and (1849) of the navigation laws (q.v.); the Irish encumbered estates act (see TITLE, etc.); the transfer (1858) of the Indian possessions from the East India company to the crown (see INDIA); the admission (1858) of Jews into the house of commons; the reform act of 1867; the disestablishment of the Irish church (1869); the Irish land acts ('70, '81); the abolition of purchase in the army (1871); the elementary education act for England (1870), and the Scotch education act (1872). See NATIONAL EDUCATION. Other events signalizing this period were the formation of the free church (q.v.) of Scotland (1843); the discovery of the northwest passage (see NORTHEAST AND NORTHWEST PASSAGES) by M'Clure (1850); the exhibitions (q.v.) of 1851 and 1862; the discovery of gold in Australia (q.v.) and in British Columbia; the war (1854–56) with Russia (q.v.) in defense of Turkey (q.v.), in which the siege of Sebastopol was the chief item; the Indian mutiny in 1857 (see INDIA); the volunteer (q.v.) movement (1859); the establishment (1866) of telegraphic communication with America (see TELEGRAPH); the Abyssinian war, 1867 (see ABYSSINIA); the formation of the dominion of Canada, 1867 (see CANADA); the Ashanti (q.v.) war (1873–74); the Afghan war (1878–80); and the Zulu war (1879). The same period has witnessed the most signal changes among surrounding nations; 1848 was a year of European revolutions, during which the only disturbance in Great Britain was an abortive chartist demonstration (see CHARTISM). The constitutional monarchy of France (q.v.) fell, and was succeeded by a republic, which soon gave place (1852) to the second empire under Louis Napoleon (q.v.), followed again by a republic in 1870. The great civil war in the United States of America (q.v.) has resulted in the extinction of slavery; the formation of the kingdom of Italy (q.v.) has been completed by the acquisition of Venetia and Rome; the unification of Germany, begun by the formation of the North German confederation, as the result of the war between Prussia and Austria in 1866, has been

consummated by the events of the Franco-Prussian war (1870–71); and the ever formidable "eastern question," raised again in 1876 by the insurrection in Herzegovina, led in 1877 to war between Russia and Turkey, and to sweeping changes in the Balkan peninsula (see TURKEY). For recent events of her reign, see GREAT BRITAIN ; EGYPT ; HOME RULE ; FENIAN, etc.

In 1876 "Empress of India" was added to the royal titles of Queen Victoria. The premature death of the prince-consort (see ALBERT) on Dec. 14, 1861, caused the queen to seclude herself for several years from public life. Queen Victoria has published three volumes—*The Early Days of His Royal Highness, the Prince Consort; Leaves from the Journal of our Life in the Highlands* (1869) ; and *More Leaves, etc.*, 1882.

"In Queen Victoria," according to Macaulay, "her subjects have found a wiser, gentler, happier Elizabeth." No former monarch has so thoroughly comprehended the great truth that the powers of the crown are held in trust for the people, and are the means, and not the end of government. This enlightened policy has entitled her to the glorious distinction of having been the most constitutional monarch England has ever seen. Not less important and beneficial has been the example set by her majesty and her late consort in the practice of every domestic virtue. Their stainless lives, their unobtrusive piety, and their careful education of the royal children have borne rich fruit in the stability of the throne, and have obtained for the royal family the admiration of the world. The 50th year or jubilee of the queen's reign was celebrated by imposing ceremonies at London, June 21, 1887, and the 60th in 1897. On the latter occasion deputies were present from all parts of the British colonies and from foreign countries. An imposing feature of the celebration was the naval review at Spithead, in which 170 ships were drawn up in five lines, nearly five miles in length.

The progress made by the nation in the various elements of civilization, especially in that of material prosperity, has been unparalleled (see GREAT BRITAIN); and perhaps during no reign has a greater measure of political contentment been enjoyed.

VICTORIA BRIDGE, across the St. Lawrence at Montreal, on the Grand Trunk railway of Canada. This, the greatest tubular bridge in the world, was begun in May, 1854 and finished in Dec., 1859. The engineers were Robert Stephenson and Alexander M. Ross. The dimensions and other particulars are stated in the article TUBULAR BRIDGE.

VICTORIA CROSS. See CROSS, VICTORIA.

VICTORIA FALLS. See ZAMBESI.

VICTORIA LAKE, called also ALEXANDRINA or KAYINGA LAKE, a brackish lagoon in the s.e. of South Australia, is separated from the sea only by a narrow belt. It receives the rivers Murray, Bremer, Angus, and Finnis, and communicates with the sea by a narrow passage that leads into Encounter bay. It is 30 m. long, and about 12 m. broad. A sandbar at the entrance to the lake impedes access for vessels from the sea; but the interior navigation is safe.

VICTORIA-N'YANZA. See N'YANZA.

VICUG'NA, *Auchenia vicugna*, a species of the same genus with the llama and alpaca. It is a more beautiful animal than any of its congeners. In size, it is intermediate between the llama and the alpaca. Its neck is longer and more slender than theirs; its wool is also finer, short and curled. It is of a rich brown color, with patches of white across the shoulders and the inner side of the legs. The vicugna inhabits the most desolate parts of the Cordillera, at great elevations; and delights in a kind of grass, the ychu (*stipa ychu*), which abounds there in moist places; but it seldom ventures to the rocky summits, for which its tender feet are ill adapted. It is commonly found in small herds of from 6 to 15 females with one male. When the females are quietly grazing, the male stands apart and carefully keeps guard, giving notice of danger by a kind of whistling sound and a quick movemen of foot. When the herd takes to flight, the male covers their retreat, often pausing to observe the motions of the enemy. If he is wounded or killed, the females gather round him, and will suffer themselves to be captured or killed rather than desert him. The vicugna is a very active animal, like the wild goat or the antelope. The Indians seldom kill it with fire-arms, but set up a circle of stakes, about a mile in circumference, into which the vicugnas are driven.

VIDA, MARCO GIROLAMO, abt. 1480–1566, b. Cremona, Italy; educated at Padua and Bologna, and became a canon of St. Mark at Mantua. In 1532 he was made bishop of Alba. Vida was a learned Latinist and profound scholar. Of his poems, the best, a treatise *De Arte Poetica* (1527); *Christias*; and *Scachiæ Ludus*; have been translated into English, the last by Goldsmith.

VIDAURRI, SANTIAGO, about 1803–67 ; b. Mexico, began life as a lawyer, served in several wars, attained the rank of gen. and became governor of Nuevo Leon, 1853, arbitrarily annexing the state of Coahuila. He assisted in the operations against Santa Anna 1854–55, in the "war of reform" 1857–60, and against French intervention, 1862–64; became cabinet minister of Maximilian; was taken prisoner at the capture of the city of Mexico, and shot as a traitor.

VIDETTE (Ital., *vedetta*, "a watch tower"), is a mounted sentry, stationed at the outposts of an army to watch an enemy and give the alarm in case of danger.

VIDOCQ, FRANÇOIS–JULES, who acquired notoriety as a detective-officer of police at Paris, was born, July 23, 1775, at Arras, where his father was a baker. On the principle

of set a thief to catch a thief his earlier life may be regarded as an almost invaluable apprenticeship to the profession in which he afterward became distinguished. As a boy, he was employed in his father's shop, the till of which, it was found, he persistently robbed. To cure him of this evil habit, he was sent to the house of correction; but so little were his morals improved there, that he signalized his return to business by decamping with a sum of about £80. Of this money, a sharper relieved him at Ostend, and in order to keep himself in life, he engaged himself to sweep the cages of a traveling menagerie. From this menial service he was advanced to the post of tumbler and acrobat; and a further promotion was intended him to that of a supposed savage, whose performance involved the eating of raw flesh, and drinking greedily of blood. As he saw fit to decline the appointment, his further services were dispensed with; and shortly after, he returned to his father. Having entered the army, he attained the rank of corporal, and served with some credit in Belgium and elsewhere, till a wound obliged him to return home. For some years after, he seems to have lived as a scoundrel at large, occupying himself in swindling and disreputable love-affairs. In 1796 he turned up in Paris, and being detected in forgery, he was sentenced to pass eight years as a galley-slave. Before his term of durance had expired, he found means to escape, and became one of a band of highwaymen. As the story goes, his new associates on chancing to discover that he was an escaped galley-slave, saw fit to decline his further acquaintance. This refinement of squeamishness on the part of these gentlemen of the road, seems not in itself very probable; but on whatever ground of dislike, they desired to rid themselves of M. Vidocq, and summarily did so, exacting from him a solemn oath not to betray them. M. Vidocq took the oath very solemnly, and instantly proceeded to deliver the whole gang into the hands of the authorities. This pretty exploit seems to have suggested to him the *rôle* which he afterward developed with such consummate success. Hieing to Paris, he offered his services to the authorities there as a spy upon the criminal classes. His advances were at first coolly received; but gradually he made his way; and shortly his services became so important that official recognition was vouchsafed him. In 1812, a "Brigade de Sûreté" was organized, with Vidocq as chief. Consisting at first of only 4 men, by degrees it was enlarged till it came to include 28; and its efficiency was something marvelous. Suspicions, however, grew rife that Vidocq was himself the originator of many of the burglaries he showed himself so clever in hunting out, and even contrived to make a good thing of them. It does not appear that this charge was in any case clearly brought home to him; but M. Vidocq being plainly the sort of person in whom any suggested blackguardism is rather more likely than not, it had every inherent probability. Guilty or not, as he may have been, so strong was the popular feeling against him that, in 1825, it led to his being superseded. After his dismissal, he became a paper manufacturer; and in 1834, established a Trade Protection society, the object of which was to furnish confidential information as to parties whose credit might be dubious. In 1829 he published an autobiography, a *rédaction* of which he put forth in 1844 (Eugène Sue's famous novel having just taken the public by storm), under the title of *Les Vrais Mystéres de Paris.* Finally, he died in Belgium in the year 1850.

VIÉLÉ, Egbert Ludovickus, b. Waterford, N. Y., 1825; graduated at West Point, 1847, served in the Mexican war, 1847–48, and in the Indian wars, 1848–52. He became a civil engineer, 1853; state engineer of New Jersey, 1854–56; chief engineer of Central Park, New York, 1856–60; and chief engineer of Prospect Park, Brooklyn, resigning to enter the union army as capt. of engineers, 7th N. Y. militia; became in 1861 brig.-gen. of volunteers; engaged in the expeditions to Port Royal, Fort Pulaski and Norfolk; was military governor of Norfolk 1862–63, resigned in 1863, and resumed his engineering practice in New York, becoming president of the department of parks, and member of congress 1884. He is a contributor to the transactions of the American geological and other societies, and published a *Hand Book for Active Service* (1861); *A Topographical Atlas of the City of New York* (1865), etc.

VIEN, Joseph Marie, 1716–1809, b. France; studied art at the academy, and after taking the grand prize in 1743 with his "Plague of the Israelites in the time of David," studied for six years at Rome. He became a member of the French academy in 1775, and director in 1781. His pictures are all of historical or mythical subjects, and he introduced a new style of painting. Among his best pictures are "Hector inciting Paris to arm for the Defense of Troy," "The Parting of Hector and Andromache," "Cupid and Psyche," "The Resurrection of Lazarus," and "The Sleeping Hermit."

VIEN'NA (Ger. *Wien*, Lat. *Vindobona*, afterward *Faviana*), capital of the Austrian empire, stands on a plain at the foot of the last hills of the *Wiener Wald*, which forms the eastern extremity of the Alps. East of it extends a vast plain, as far as the eye can see, away to the Carpathians, which are visible on a clear day in the distance. On the n. the hills approach within half a dozen m. of the city, and extend uninterruptedly, to the w., to the Tyrolese Alps. An arm of the Danube (called a canal) passes along the n.e. side of the city, and separates it from the suburb of Leopoldstadt. Into this arm flows the foul and (when not swollen by rains) insignificant stream, called the Wien, from which the city takes its name. Vienna consists of the old city or inner town, called the *Stadt*, with narrow and irregular streets, and of a circle of suburbs, eighteen in number, completely surrounding it. Around the *Stadt*, and separating it from the suburbs, is a ring space upon which were formerly the fortifications, leveled in 1858,

and which has been converted into a series of handsome boulevards 62 yards in breadth, known as the Ringstrasse, comprising the *Burgring*, *Opernring*, *Kärntherring*, etc., and architecturally one of the finest streets in Europe. Besides the internal fortifications just mentioned, there is an external ring with rampart and fosse, erected in 1704 as a protection against the Hungarians. These fortifications are called the *lines*, and at one time encircled both suburbs and city and were preserved as the boundary-line of the city imposts, until 1890, when the city limits were extended, to include nine additional districts, with a total circumference of 39 miles, in place of the former 23 m. Unlike most other European cities, the old part of the city is the most fashionable. In the *Stadt* are the palaces of the emperor and of some of the principal nobility, many stately mansions, the public offices, the finest churches, most of the museums and public collections, the colleges, the exchange, and the best shops. Since the erection of the Ringstrasse and other buildings upon the site of the old glacis, however, very many of the aristocracy have gone there to live. The suburbs are laid out in wide streets, many of which, being unpaved, are extremely dusty in summer, and very muddy in winter. As a rule, the houses are let in "flats," almost the only exception to this being the palaces of the higher nobility, and in some cases even these consist only of the two lower stories of the building. Among the principal squares are the *Josephsplatz* and the *Burghof* (the latter the court of the palace); the outer *Burgplatz*, which is laid out with grass and flowers, and in which stands the *Burgthor*, the *Neuer Markt am Hof*, and *Frieung*. The last three are in the heart of the city, contain many picturesque buildings, and are otherwise interesting, standing as they do in much the same relation to Vienna as the Grassmarket to Edinburgh. Vienna is the see of an archbishop; and the chief of its many churches is the cathedral of St. Stephen. This church is 354 ft. long, 229 ft. broad, and 80 ft. high, and has a very beautiful tower, 450 ft. high, erected in 1860–64, to replace the former structure, which was removed because of its unsafe condition. Its different parts have been built at many different periods, the choir having been commenced in 1359, while the nave dates a century later. The church of the Augustines is remarkable for its monument of the archduchess Christina of Saxe-Techen, one of the most successful works of Canova. The most beautiful church in Vienna, and one of the most beautiful in the whole of Germany, is the *Votiv-Kirche*, built in commemoration of the emperor's escape from assassination in 1853. It is a Gothic church not completely finished till 1878, with two towers and spires, and covered with delicate and beautiful tracery and carving. The imperial royal palace is an ancient building, consisting of various parts, erected at different times. Adjoining the palace, or forming part of it, are the extensive imperial library, the treasury, the cabinet of coins and antiquities, etc. Among the other collections of interest are the belvedere, including the Ambras collection (pictures, sculptures, and antiquities); the arsenal; the Liechtenstein gallery; count Harrach's collection (pictures); and the Albertina (drawings and engravings), the latter containing the original study of Raphael's "Transfiguration." The polytechnic institution (for instruction in practical science, etc.) is attended by about 1000 pupils, and in connection with it there is a capital technological museum. The university (founded 1365) had in 1893–4 upward of 6600 students on its roll (of whom upward of 3500 are in the faculty of medicine), a staff of over 400 professors and lecturers, and a library of 320,000 vols. As a school of medicine it is celebrated all over the continent. The principal places of public resort for the lower classes are the gardens of the palace at Schönbrunn, the *Augarten*, and the *Prater*, the latter being probably the largest park in Europe. Vienna contains two imperial theaters, the magnificent opera-house, and the *Hofburg Theatre*, and numerous private theaters, the *Deutsches Volkstheatre*, *Theatre an der Wien*, etc. The industries of Vienna are of great importance and include the manufacture of machines and locomotives, carriages, mathematical, optical, physical, and surgical instruments, pianos, fireproof safes, lamps, jewelry, gold and silverware, chemicals, perfumery, paints, varnishes, silk, woolen, and cotton fabrics, carpets, shawls, etc. Gloves, fancy leather goods, and meerschaum pipes figure among the specialties of Vienna. Very extensive works were begun in 1869, designed to bring the Danube closer to the city and improve its navigation. These were completed in 1880 at a cost of more than £2,000,000, and are expected to make V. the staple place of ship-trade between east and west, as it already is the main center of railway communication. The V. observatory was equipped in 1881 with the largest telescope hitherto made. Pop. of V. '96, 1,526,623.

VIENNA, TREATIES, ETC., OF. This capital, from its central position, and from the prominent part which Austria has always taken in the wars of modern Europe, has been oftener selected than any other city (Paris perhaps excepted) as the meeting-place of the representatives of the various European nations. The *first* treaty of Vienna (April 30, 1725) was a mutual guaranty of their dominions by the emperor Charles VI. and Philip V. of Spain; besides which, the former agreed to aid in the recovery of Gibraltar from Britain, and to aid the pretender in supplanting George I., in consideration of the latter guaranteeing the pragmatic sanction. The *second* treaty (Mar. 16, 1731) was a joint guaranty of the pragmatic sanction by George II. of Britain and the states of Holland. The *third* (Nov. 18, 1738) was a similar guaranty by Louis XV. of France in consideration of the reversion of Lorraine and Bar (to be given meantime to Stanislas, the ex-king of Poland), as well as a settlement of the Polish succession dispute, and a

re-arrangement of the possessions of Austria, Spain, and Sardinia, in Italy. The *fourth* treaty (Oct. 14, 1809) was concluded between France and Austria, after the battle of Wagram, and the armistice of Znaim, by which the latter agreed to resign some districts on the western border of the archduchy to Bavaria; Goritz, Friuli, Trieste, Carniola, and parts of Croatia, Carinthia, and Dalmatia, to France, these provinces to be formed into the government-general of Illyria; some districts of upper Lusatia to the king of Saxony; western Galicia, with Cracow and Zamocz, and a share in the salt mines of Wielicza, to the grand duchy of Warsaw; and the eastern corner of Galicia to Russia; a total loss to Austria of 58,170 sq.m., with a pop. of 3,500,000, and all her sea-ports.

The next, and by far the most important meeting of the representatives of European nations, was the *congress of Vienna*, which was held here after the first treaty of Paris, for the general settlement of the affairs of Europe. The congress, which first met on Sept. 30, 1814, was composed of the czar Alexander I., of Russia, with count Nesselrode; the king of Prussia, with Hardenberg; lord Castlereagh, and afterward the duke of Wellington, as representatives of Britain; prince Metternich for Austria; count Talleyrand for France; as well as representatives of Spain, Portugal, Sweden, Rome, Germany, and all the other minor powers, who were interested personally in the deliberations; the total number of those who assisted at the congress being about 500. But the representatives of the minor states, who had expected a species of European parliament, to which all would be admitted, were sadly disappointed by the preliminary resolution of the great powers to constitute two committees, one of which would deliberate on the affairs of Germany; and the other, composed only of the representatives of Austria, Prussia, Russia and Britain, would discuss the affairs of Europe generally, decide respecting the partition of the conquered districts (formerly belonging to France and her allies), and the frontier of each European sovereignty. To this latter council, Talleyrand, by the influence of Castlereagh, who early saw the necessity of a counterpoise to the influence of Russia and her follower, Prussia, in the conferences, was admitted (Oct. 5); and three days after, it was increased by the representatives of Spain, Sweden, and Portugal. The first resolution of the European committee, to rearrange Europe so as to leave the parties directly interested nothing more to do than give their adhesion to the arrangements made for them, being an arrogation of sovereignty over all Europe, was loudly exclaimed against; but the congress was one of rulers and *their* representatives, and not of the nations and *their* representatives, so the indignant clamor which rose on all sides was quite unheeded. The points which were at once and unanimously settled were—the constitution of Belgium and Holland into one kingdom (*the kingdom of the Netherlands*); the annexation of Norway to Sweden; the restoration of Hanover, with a large slice of Westphalia, to the king of Great Britain; of Lombardy to Austria; and of Savoy to Piedmont. But the question as to the disposal of Poland, Saxony, and Genoa, were not so easily settled. Russia and Prussia, overweeningly vain of the prominent share they had had in crushing Napoleon, were bent on aggrandizement of the most extravagant sort; the former loudly insisting on obtaining the whole of the grand duchy of Warsaw (see POLAND); while nothing less than the whole of Saxony, and some of the trans-Rhenish provinces of Westphalia would satisfy the latter; and both significantly hinted at the proximity of their colossal armies, with the view of awing the other powers into compliance. But Castlereagh was not the man to be so influenced; and while steadily refusing to yield an iota to such preposterous pretensions, he joined with Metternich and Talleyrand in a secret treaty, offensive and defensive, Feb. 3, 1815; which was cordially acceded to by Hanover, Sardinia, Holland, and Bavaria. The news of this agreement soon leaked out, and produced a considerable modification in the pretensions of the northern powers. At last it was agreed that Prussia should obtain a portion of Saxony (now Prussian Saxony), Posen, Cleves, Berg, the greater part of the left bank of the Rhine as far as the Saar, and Swedish Pomerania; and cede East Friesland, Hildesheim, etc., to Hanover, Anspach and Baireuth to Bavaria, and Lauenburg to Denmark; while with the exception of Posen, Thorn, and those parts of the grand duchy which had been (1809) taken from Austria, Poland was to be erected into a kingdom separate from Russia, but under the rule of the czar. Austria recovered the cessions which she was forced to make in 1809, obtaining also the Valteline from Switzerland, and the establishment of collateral Hapsburg lines in Tuscany and Piombino; while Maria Louisa obtained Parma. The pope was replaced in his former position as a temporal sovereign; the ancient constitution of Switzerland re-established; and Genoa—despite the strongly expressed aversion of its inhabitants—incorporated with Sardinia. The news of Napoleon's return from Elba somewhat hurried the conclusion of these multifarious arrangements, yet the negotiations were not interrupted; Metternich's scheme for a new confederation of the German states (the same which has continued till 1866) was unanimously agreed to, the question of mutual indemnities, rectifications of frontier, etc., being subsequently settled (July 20, 1819) at Frankfort, by a territorial commission composed of representatives of the four great powers. The questions of the slave trade and of the free navigation of the Rhine and its tributaries, were brought up by England, and also satisfactorily settled. Finally, a formal treaty (the *fifth treaty of Vienna*) was drawn up and signed, June 9, 1815.

VIENNA PASTE is a preparation which is extensively used as an encaustic, although it is not contained in the Pharmacopœia. A mixture, termed *potassa caustica cum calce*

(caustic potash with lime), which is itself a caustic, and is much employed for producing issues, is first prepared by mixing equal weights of caustic potash and freshly burned lime in a warm mortar, and rubbing them to a powder, which should at once be placed in an air-tight bottle. The caustic powder of which Vienna paste is made is obtained by similarly mixing 50 parts of the preceding compound with 60 of quick-lime. It must be kept in a well-stoppered bottle; and when required for use, the powder is made into a soft paste with a little spirit, and applied to the part it is desired to cauterize. It is much employed by some physicians in certain affections of the womb; and is one of the best applications to an indurated chancre. See SYPHILIS.

VIENNE, an interior dep. in the w. of France, bounded on the n. by the deps. Maine-et-Loire and Indre-et-Loire, and on the w. by Deux-Sèvres, which intervenes between this and the maritime dep. of Vendée. Area, 2691 sq. m.; pop. '96, 338,114. The Vienne, an affluent of the Loire, is the principal river, and all the other streams of the dep. are tributary to it. It flows from s. to n., and receives the Clain, with its tributary, the Gartempe, and the navigable Creuse. The surface is flat with a gradual slope toward the north. The country consists almost wholly of fertile plains, fine pasture-lands, and extensive forests. The climate is soft, temperate and healthy. Wheat, rye, barley, oats, and fruits are abundantly produced and the annual yield of wine is very large. The mineral riches of the department consist principally of iron and manganese, and numerous quarries of building and other stones, including lithographic stones, which are finer and harder than those of Munich. The dep. is divided into the five arrondissements of Poitiers, Châtelherault, Civray, Loudun, Montmorillon. Poitiers is the capital.

VIENNE, one of the most ancient t. of France, in the dep. of Isère, on the left bank of the Rhône, 19 m. s. of Lyons by railway. The river Gère passes through the town, and here joins the Rhône, after having supplied motive-power to a number of mills and factories. Vienne was the chief town of the Allobroges, is mentioned by Cæsar (*De Bello Gallico*, vii. 9), and by Martial, who terms it *opulenta Vienna*. At the time of the Roman emperors, it was a rival of Lyons. Besides numerous water-conduits, etc., of Roman construction, there is a temple supposed to have been dedicated to Augustus, and which is now used as a museum, and contains a number of ancient Roman remains. There are also a Roman arch, remains of a theater, and an antique pyramid, called L'Aiguille, 52 ft. high; and the cathedral of St. Maurice, a stately Gothic edifice, with much delicate carving. Manufactures of silks and woolens are carried on; and there is a good trade in wine. Pop. '91, 24,817. In 1312 a council was held here, in which Pope Clement V. pronounced the suppression of the order of the Templars.

VIENNE, HAUTE, an interior dep. of France, bounded on the w. by the deps. of Vienne, Charente, and Dordogne; area, 2130 sq. m.; pop. '96, 375,724. It is watered by the Vienne and its tributaries—the chief of which is the Gartempe. The surface is for the most part level; but traversed by ranges of low hills, of which the Monts du Limousin, which traverse the s. of the dep. from e. to w., rise in their highest summit to 3000 feet. The Mont de Puy-Vieux, the highest in the dep., is 3200 ft. above sea-level. The climate is cold, humid, and changeable. The soil is stony, and agriculture is in a very backward condition. There are, however, extensive meadows, and the domestic animals are reared in great numbers. Mines of iron, lead, copper, and antimony are worked, and there are quarries of granite and other building-stone, and in the south, near St.-Yrieix, valuable deposits of kaolin. The dep. is divided into four arrondissements—Limoges, Bellac, Rochechouart, and St.-Yrieix; capital, Limoges.

VIER'SEN, a prosperous and beautiful manufacturing t. of Rhenish Prussia, 18 m. w. of Düsseldorf. Viersen has extensive manufactures of flax and hemp rope, as also of woolen, damask, silk and velvet stuffs, and ribbons; there are also dye-works and manufactories of knitting machines. The population of Viersen has more than doubled itself within the last few years, being in '90, 22,198.

VIERZON-VILLE, a t. of France, situated on the Cher and the Canal du Berry, in the dep. of Cher, 49 m. s. of Orleans. Vierzon-Ville has blast furnaces, forges, and steel-refineries, manufactures of porcelain and earthenware, and a trade in cereals and wine. Pop. '91, 10,559.

VIETA (otherwise given VIET, VIETTE, or DE VIETTE, and by himself Latinized into VIETÆUS), FRANÇOIS, 1540–1603, the most eminent French mathematician of the 16th c., was b. at Fontenai-le-Comte, near La Rochelle. Of his early life and education we know nothing, and almost all our acquaintance with the meagre details of his personal history is derived from the records of his friend, De Thou (see THOU). Vieta was employed throughout his whole life in the service of the state under Henry III. and Henry IV., and devoted only his hours of leisure to the study of mathematics and other subjects—affording an excellent illustrative argument against the belief that abundant leisure is essential to high eminence, and in favor of the contradictory theory that mental work of whatever sort tends to prepare the mind for any other species of thought-labor. Vieta was a zealous Roman Catholic, and a strenuous supporter of the doctrine of the divine right of kings. His genius and persevering industry brought him prominently into notice on various occasions. During the war against the Spaniards, the latter, to preserve as much as possible their communications with their numerous

outlying possessions, and prevent the French from profiting by information from intercepted letters, adopted a species of cipher (see CRYPTOGRAPHY) of more than 500 characters, each varying from time to time in its signification. Some specimens being intercepted, were submitted to Vieta, who after a time discovered a key to the cipher, to the great discomfiture of the Spaniards, who, incapable of accounting for the discovery otherwise, attributed it to magic; though the story that Vieta was summoned to Rome to defend himself before the pope against the charge of having dealings with the devil may safely be regarded as untrue. Vieta's next prominent appearance was an as assailant of the Gregorian calendar, in opposition to which he published (1600) a "true Gregorian calendar," which was with justice considered by his contemporaries as inferior to that which obtained the papal sanction. However, Vieta did not, or would not, see his error, and attacked the Jesuit Clavius, to whom the pope had intrusted the compilation of the calendar, in a bitterly abusive manner; displaying, however, such a mastery of knowledge, that one of Clavius's defenders was led to sympathize with the unfortunate Jesuit who had to withstand the assault of one who was at once a lawyer, theologian, mathematician, orator, and poet. Vieta, however, is almost exclusively recognized by posterity as a mathematician; yet, though worthy to rank among the highest of this class, immediately after such men as Newton and Lagrange, the incessant state of politico-religious turmoil in which France was kept during his life, and the fact that all his works printed during his life were set up at his own expense, and distributed among his friends, have hitherto hindered a general recognition of his high merit. The Italian tabulators of the progress of mathematical science have thus had a good opportunity of decking out their national idols (Cardan, especially) with plumes stolen from the obscure French investigator. The claims of Vieta, however, are now becoming more and more generally recognized. He is indisputably entitled to be considered as the creator of modern algebra, which he established on the footing of a purely symbolical science; he applied his algebra to the extension of trigonometry, discovered the relations of multiple angles; and he extended the ancient process of extracting square and cube roots to the solution of all equations, an extension which has been since modernized and modified, and now appears as *Horner's method.* Besides, he proved his superior mathematical powers, by solving problems which had puzzled Apollonius, Regiomontanus, etc.; and was acknowledged by the mathematicians of Belgium and Italy as their master. Yet, strange to say, his own countrymen, the French, have so little knowledge of the surpassing talents and achievements of Vieta, that, omitting all intelligent mention of his peculiar successes, they ascribe to him praises due to his Italian predecessors, and to his great English successor, Newton. Most of Vieta's works were collected by Schooten, and published by the Elzevirs, at Leyden, in 1646. Two other works of his have been recently discovered, the *Harmonicon Cœleste* and the *Canon Mathematicus*, the latter the first table in which the trigonometrical functions of an angle are completely given. Of the first, two MSS. exist; while the second was printed and circulated according to Vieta's usual fashion, and has long been a bibliographical curiosity; but neither has yet been published. See Knight's *Eng. Cyc.* art. "Vieta."

VIEUXTEMPS, HENRI, b. Belgium, 1820; displayed proficiency on the violin when but a child, and was a pupil of De Bériot and Reicha. In 1830 he appeared at Paris and Vienna in public concerts, with great success, and was always marked by the public as one of the masters of his instrument. He visited America in 1843, 1855, and 1870, appearing on the last occasion in concerts with Mlle. Nilsson. He d. 1881.

VIEYRA, ANTONIO, 1608–97; b. Lisbon: entered the Franciscan order, and became the foremost preacher in his country. He went on diplomatic missions to various foreign courts, and in his last days was a missionary to Brazil.

VIGFUSSON, GUDBRAND, author and editor, b. in west Iceland, March 13, 1827, was descended from ancient Icelandic or Norse families. At twenty years of age he entered the University of Copenhagen, Denmark. His first literary essay was *Timatal, an Essay on the Chronology of the Icelandic Sagas* (old northern European popular historical or religious tales) in Icelandic (1854–55). It was followed by kindred productions, including collections of Sagas in Danish and Icelandic. In 1864 Mr. Vigfusson visited England, and was engaged in work upon a great Icelandic dictionary. Subsequently he edited other sagas (in England), and conjointly with Mr. York Powell (1879) an *Icelandic Reader*, etc., etc. In 1871 he was made an honorary M.A. of the University of Oxford, England, and in 1884 became professor of Icelandic language and literature there. He d. in 1889.

VIGIL (Lat. *vigilia*, Fr. *vigilo*, I watch), a preparatory time of devotion, which, by very ancient Christian usage, went before the more solemn festivals, and especially Christmas, Easter, Pentecost, and the principal martyrs' days. In English, it was called "eve" or "even," a name which is still retained in relation to several festivals, as Christmas eve, Hallow-e'en, etc. The observance is traceable in the very earliest centuries, and was established everywhere in the 4th and 5th centuries. It is one of the usages of his time against which Vigilantius inveighs, and which Jerome vindicates in his celebrated *Letter against Vigilantius.* On the day before the great festivals, which seems from the first to have been held as a fasting-day, the people assembled in great multitudes. The services proper to the vigil, but having a certain bearing on the coming festival, were celebrated; the night was spent chiefly in the church and in prayer, and other devotional

exercises; but abuses arose out of these night-watches, which led to their suppression, as well as to the abolition of certain festivities which grew up in connection either with the vigil or with the feast itself. The observance of vigils is still retained in the Roman Catholic church, and with it all the ecclesiastical offices, together with the fast, at least in the great vigils of Christmas, Easter, Pentecost, Saints Peter and Paul, Assumption, All-Saints, etc.; but all the other details of the celebration have gone into disuse. In the English prayer-book, the "vigils or evens" of the chief festivals of our Lord, of the blessed Virgin Mary, and of the Apostles are retained in the calendar; but they have no special services appointed for them, nor any other celebration. See Blunt's *Annotated Common Prayer*, p. 28.

VIGIL'IUS, b. in Rome, was, while a deacon, nuncio at Constantinople during the pontificate of Sylverias. Theodora, wife of Justinian, determined to depose Sylverias, and sent Vigilius to Rome to procure his imprisonment and exile. Vigilius was, at Theodora's suggestion, elected pope, 537. In 547 he was summoned to Constantinople by Justinian to sustain him against the western bishops in his condemnation of the "three chapters," i.e. of the writings of Theodore of Mopsuestia, Ibas of Edessa, and Theodoret. Vigilius considering the writings orthodox, refused to condemn them, and was banished to the island of Proconnesus, from which he was recalled, 554. He died on his way to Rome in 555.

VIGNETTE' (Fr. little vine, a tendril; Lat. *viticula*), a term originally applied to the flourishes in the form of vine tendrils, branches, and leaves with which the capitals in ancient manuscripts were often surrounded. Similar decorations were introduced into printed books, and all kinds of printers' ornaments, such as head and tail pieces, came to be designated as vignettes. More recently, the name has been applied to any small engraving (as on the title-page of a book). design, or even photograph, which is not circumscribed by a definite border.

VIGNOLA, GIACOMO BAROZZIO DA, 1507–73, b. Modena; studied painting at Bologna and architecture at Rome, and under Primaticcio in France. He returned to Bologna, and was chosen as the architect of several palaces and public buildings. In 1550 he was made papal architect by pope Julius III., and the latter part of his life was spent in Rome, where he designed the Caparola palace and the church of the Jesuits. He became the architect of St. Peter's after the death of Michael Angelo, and designed the two lateral cupolas. The designs for the restoration of the Spanish Escurial were his work. He was the author of *The Five Orders of Architecture* and *Practical Perspective*, still standard works.

VIGNY, ALFRED COMTE DE, a French poet and novelist, was born at Loches in Touraine, March 27, 1799, and educated at Paris. After spending some time as a soldier, he married, in 1826, a wealthy Englishwoman; and two years later, withdrew from the army, in order to devote himself exclusively to literature. He died Sept. 18, 1863. Vigny belongs to the romantic school, but is free from all their extravagance of style and sentiment. No modern French poet exhibits an equal refinement and delicacy. His principal works are *Poèmes* (1822); *Poèmes Antiques et Modernes* (1824–26), among which are his famous *Moïse, Dolorida*, and *Elva; Cinq-Mars* (1826), a historical romance of the time of Louis XIII., which is much admired in France, and has gone through more than a dozen editions; *Stello ou les Diables* (1832); *Servitude* and *Grandeurs Militaires* (1835)—two very striking and suggestive novels; *La Maréchale d'Ancre*, and *Chatterton* (1835)—dramas of considerable merit. Beside these, he published *Consultations du Docteur Noir* (1856). A posthumous work appeared in 1864, entitled *Les Destinées, Poésies Philosophiques.* See life by Dorison (Paris, 1892).

VIGO, a co. in w. Indiana, having the Wabash river and the state line of Illinois for its w. boundary; 410 sq. m.; pop. '90, 50,195, chiefly of American birth, with colored. Co. seat, Terre Haute.

VI'GO, an ancient town and seaport on the n.w. coast of Spain, in the province of Pontevedra, beautifully situated on a bay of the same name, about 85 m. n. of Oporto. Its delicious climate renders it important as a medical station; and its position on the slopes of a hill, oriental in its wealth of palms and orange-groves, is likely to tell in its favor as a residence for the rich. Its old walls and gates; its winding, narrow streets; its houses, white-washed, or colored red or green; the craft which frequent its harbor, and the picturesque dresses of the peasants, are delightful to the artist, as well as to the ordinary observer. Vigo has three churches, two convents and a theater. The country in the vicinity is exceedingly rich, and fruits, corn, wine, and oil abound. It exports considerable quantities of wines, preserves, sardines, and mineral waters. Pop. '87, 15,044.

The bay of Vigo has an inland sweep of 20 m., and is 5 m. wide at its mouth. The town has frequently been attacked by the English; by Drake in 1585 and 1589; by the duke of Ormond, Rooke, and Stanhope in 1702; and in 1719 by lord Cobham.

VIHÂRA (Sanskrit, meaning "walking for pleasure or amusement") is, with the Buddhists (see BUDDHISM), the name of their temples and convents. Originally it designated the hall or halls where the Buddha Sâkyamuni, and the priests by whom he was accompanied, used to meet; but when these halls gradually were converted into temples, the

name of *vihâra* was applied to them; and when, in time, the temples became the center of a number of habitations in which the priests belonging to the temples resided, the whole monastic establishment was comprised under the same name. Properly, therefore, the Vihâra merely designates the Buddhistic temple, and it is generally used in this restricted sense. Such vihâras are in Ceylon permanent structures, the walls being plastered, and the roof covered with tiles, even when the dwellings of the priests are mean and temporary. Near the entrance are frequently seen figures in relievo, representing the guardian deity of the temple. Surrounding the sanctum there is usually a narrow room, in which are images and paintings; and opposite the door of entrance there is another door, protected by a screen; and when this is withdrawn, an image of Buddha is seen, which occupies nearly the whole of the apartment, with a table or altar before it, upon which flowers are placed. The walls of the vihâra are covered with paintings, and its stories generally illustrate some legend of Buddha's life. Some vihâras are built upon rocks; others, and among these the most celebrated, are caves, in part natural, with excavations carried further into the rock. The cave-temple at Dambulla is one or the most perfect vihâras in Ceylon (see the description of it by Forbes in the *Ceylon Almanac* (1834). On the continent of India, the finest specimens are those at Ajunta, Ellora, Salsette, and Junir. Sometimes no land is attached to the vihâras, but sometimes also they are rich in land; and in the case of one of the vihâras in Kandy, there is an area belonging to it, which, under the native government, was regarded as a sanctuary for malefactors. See R. Spence Hardy, *Eastern Monachism.*

VIKING (plural Vikingr), a name given to the piratical Northmen who infested the coasts of the British islands and of France in the 8th, 9th, and 10th centuries. This word is quite unconnected with "king," being derived from the Scandinavian *vik*, a bay; and this class of marauders were so called because their ships put off, not like the king's ships, from the lawful harbor, but from the bay. See Normans.

VILAS, William F., b. Chelsea, Vt., 1840; graduated at the Wisconsin state univ., 1858; and at the Albany law school, 1860. He began the practice of law, and became one of the law lecturers at the state univ. In 1884 he presided over the national dem. convention; in 1885–88 was postmaster-gen.; in 1888–9, secretary of the interior; and in 1891–97 was U. S. senator.

VILAYET, the name given to the provinces of Turkey. Each vilayet is governed by a gov.-gen. and council, and is subdivided into sanjaks or liv'as, and again into cazas.

VILLA, a term now applied to detached suburban residences with about one acre or less ground attached to them. In the time of the Romans, the villa was a cluster of buildings in the country, forming a sort of private town, and containing in one the residences of the proprietor, farmer, and servants, and all the necessary offices and other accommodation for the cattle—the gardens, pleasure-grounds, etc. These villas were sometimes of enormous size, but they do not seem to have been built on any regular architectural plan, so as to produce an effect commensurate with their extent. The villa was divided into several parts, according to their uses: 1. The *villa urbana* was the portion in which the proprietor resided, and was laid out, as the name indicates, in a manner very similar to that of a town-house. The size and style of this part depends, of course, on the pleasure or quality of the master. It contained the eating-rooms, bedchambers, baths, covered porticos, walks, and terraces. 2. The *villa rustica* was the portion set apart for the stabling, servants, etc., and the accommodation for the cattle. Its extent depended on the size of the farm and number of cattle. 3. The *villa fructuaria* was for the wine, oil, and other produce. The number of servants accommodated in a villa was very great. The livery-servants, along with the gardeners for the pleasure-grounds, comedians, musicians, etc., belonged to the villa urbana. The *villicus* presided over the others, including the servants for tilling the land, the herdsmen, shepherds, goatherds, swineherds, poulterers, etc. There were also frequently several artisans, kept constantly on the premises, such as smiths, carpenters, etc.

VILLAFRANCA DI VERONA, a small t. of northern Italy, in the province of Verona, and 9 m. s.w. of the city of that name, on the left bank of the Tione, a tributary of the Tartaro. It is notable chiefly as the place where the treaty of peace between the emperors of France and Austria, which brought the Italian war of 1859 to a close, was signed July 11 of that year. Pop. commune, 8693.

VILLAFRANCA DEL PANADÉS (of the bakers), a t. of Spain, in the province of Barcelona, in Catalonia, 25 m. w. of Barcelona. It is the chief town of the rich wine district, El Panadés, which extends into the province of Tarragona. Pop. '87, 8344.

VILLANELLA (Italian), a rustic dance accompanied with singing. The melody was usually gay and the rhythm well marked. When words were used they resembled epigrams. The villanella ultimately became unaccompanied, part songs sharing the characteristics of the canzonetta and the balletta. The villanella of the Neapolitan school of the 17th century are among its most charming light productions. The best example of a modern villanella is Sir Julius Benedict's *Blest be the Home.* The Italian villanella and villotte, a rustic composition in counterpoint and the Spanish villancico, a species of song in two or more stanzas belonging to the 15th century, were the precursors of the madrigal.

VILLA'NI, Giovanni, 1280–1348; b. Florence; visited many parts of Europe; became celebrated as a historian and diplomat, and considered an authority on the Tuscan language. He belonged to the Guelph party, and filled many offices in the people's gift. He died of the plague. A chronicle of Florence (*Istorie Fiorentino*), in 12 books, was published in 1562–87, the 13th vol. being added by his brother Matteo, whose son Filippo continued it to 1365. It appeared in 7 vols. (1802), with a eulogy of Villani by Massai.

VILLA-REAL, a t. of Valencia, Spain, in the province of Castellon, and 5 m. s. of the city of that name, about 3 m. distant from the Mediterranean shore. It has wide, straight streets, laid out at right angles to one another, and contains flour and oil mills, woolen factories, and brandy distilleries. Pop. 12,887.

VIL'LARI, Pasquale, b. Naples, 1827. When in the university he became involved in the revolutionary movement of 1848–49, and was forced to leave the country. He resided at Florence for some years, and there published his *Life of Savonarola* (1859–61), which has been translated into many languages, and *Niccolo Machiavelli* (1877–82; new ed. 3 vols., 1895). He was afterward professor of modern history at Pisa and at Florence; general secretary of public instruction; deputy and senator in parliament; minister of public instruction, etc. He published many papers on education and of a critical nature.

VILLA RICA, a c. of Brazil, capital of the province of Minas Geraes, called also Ouro Preto (q. v.).

VILLARS, Charles-Louis-Hector, Duc de, Marshal of France, one of the most illustrious of the great captains of Louis XIV.'s time, was born at Moulins, in the department of Allier, May 8, 1653. Being of a noble family, his education, with a view to the military profession, was prosecuted at the college of Juilly, and he subsequently volunteered into the army which was employed in Holland; and having attracted Louis XIV.'s attention by his daring courage and striking elegance of figure, obtained a troop of horse in 1672, served for two years under Turenne in Germany, and after the battle of Seneffe received a regiment of cavalry, when yet in his 21st year. After a further term of service under Luxembourg and Crequi, he returned to Paris with the reputation of being one of the most promising young officers of the time. During the next ten years (1678–88) he was employed in diplomatic service, chiefly at the court of Bavaria. In 1688 Louvois appointed him commissary-gen. of cavalry; and, in the war which immediately followed the league of Augsburg, placed him at the head of the cavalry in Flanders. He was subsequently distinguished in the campaigns on the Rhine and in Italy. From 1699 till 1701 he represented France at the court of Vienna, and watched with sleepless vigilance the tortuous policy of the Austrian ministers, foiling by his penetration their most promising schemes, till he came to be regarded personally with extreme dislike, was shunned by all the court (prince Eugene excepted), and even his life threatened. On his return, he was employed in Italy under Villeroi; and, after a brief period of service under Catinat, was for the first time (1702) raised to independent command, when he was sent to succor the elector of Bavaria, who had taken up arms on the side of France. Toward the close of 1702 Villars crossed the Rhine, defeated the markgraf of Baden at Friedlingen, took Treves, Traerbach, and Nancy; and early in the following year, again crossed the Rhine, traversed the almost impassable defiles of the Black Forest, and, debouching from the mountains at Villingen, joined the elector near Dutlingen, on May 12. His bold and well-conceived scheme for carrying the war into the enemy's country by advancing upon Vienna, while so many Austrian troops were employed on the middle Rhine, in Italy, and against Ragotski in Hungary, was foiled by the stupid obstinacy of his colleague, the elector; and after his skill and genius had been tasked to the utmost to keep the Austro-Germans under the markgraf of Baden and Stirum at bay, and he had been relieved by the return of his ally (who had been soundly beaten by the Tyrolese mountaineers), he reopened his line of communication westward, and, leaving Marsin in command, returned in disgust to France. He was next commissioned to put down the insurrection of the Camisards (q.v.), which had been zealously fostered, for strategic reasons, by English and Dutch agents. Villars's manly moderation and soldierly frankless fairly won over Cavalier, the ablest of the insurgent leaders; and might, with his consummate military skill, have suppressed the insurrection. However, he was not allowed to manage matters for himself, and all he could do was to reduce the ferment to insignificant proportions. Villars was then sent to watch over the north-eastern frontier, and took post on the heights of Fronsberg, when Marlborough advanced upon him with 110,000 men; but Villars had shown such skill and strategy in the selection and fortification of his position, and such wise self-control in remaining strictly on the defensive, that the great English hero declined to risk an attack, and retreated; upon which Villars burst into Alsace, captured the enemies' reserves of supplies and artillery, and advanced to Rastadt and Stuttgart. The withdrawal of some of his troops to re-enforce the north French army forced him to recross the Rhine; yet, with his small army, he, in 1708, completely foiled all the attempts of prince Eugene to penetrate into France. In 1709 he was sent to oppose Marlborough in the north; but unfortunately, at the commencement of the battle of Malplaquet (q.v.), he was severely wounded, carried off the field insensible, and rendered unfit for service till the following year; and the reopening of his wound in the autumn of 1710 forced him again to resign the command. But in 1711 he returned to his post, headed the last

army France could raise, and with it fell upon the British and Dutch under Albermarle, who were intrenched at Denain (July 24, 1712), carried their intrenchments sword in hand, and captured the most of them; he then turned upon prince Eugene, and drove him under the walls of Brussels. This magnificent series of successes saved the national honor, and even life, of France, and brought about the peace of Rastadt (see UTRECHT), which Villars signed as plenipotentiary, May 6, 1714. After the peace, he became, at court, the principal adviser on military affairs and on questions of foreign policy; was a strong opponent of Law's financial measures; but, through the intrigues of Fleury, lost favor at court. The outbreak of war in 1732, however, brought out the old hero from his retirement, and with the title of "marshal-gen. of the camps and armies of France" he went to head the French army in the Milanese. The campaigns of 1733–34 showed that the weight of years had left Villars's military genius and spirit untouched; but the ill-behavior of his ally, the king of Sardinia, determined him to solicit his recall; and he accordingly set out for France; but falling ill at Turin, he died there, June 17, 1734. Villars was the last of the great military geniuses of the French monarchy, and was wholly free from the restless anxiety for *éclat* which detracts from the merits of so many of them. As a general, he possessed in a high degree rapidity of apprehension, skill in disposition, and promptitude (without precipitancy or rashness) in action. Humanity and sincerity, joined to thorough self-reliance, may be traced through the whole of his long and eventful life; and the two latter qualities occasionally exhibited themselves so prominently at court as to cause the "professional courtiers" of Louis XIV. to look askance upon him as a "rude and *immodest*" person. His memoirs have been printed in Holland, and his autobiography by Anquetil.

VILLARSIA, a genus of plants of the natural order *gentianaceæ*, the species of which are widely distributed over the world, and are either aquatic or marsh plants, with entire leaves and yellow flowers. Villarsia *nymphæoides* is a native of England, but rare. It is more common in many parts of Europe, from Denmark to the Mediteranean, and is very abundant in Holland, often covering large tracts of the canals with its beautiful flowers and leaves. It abounds in the south of Siberia. It is easily cultivated.

VILLEFRANCHE, a t. of France, in the department of Aveyron, is seated on the Aveyron river at its confluence with the Alzou, 76 m. n.e. of Toulouse by railway. It contains many interesting houses of the 15th and 16th centuries, a church of Notre Dame (13–16th cent.), an old Carthusian convent, with interesting Gothic cloisters, and carries on manufactures of copper wares, iron, gray cloths, etc. Pop. '91 (commune), 9734.

VILLEFRANCHE-SUR-SAÔNE, a small industrious t. of France, in the department of Rhône, stands on the Morgon, an affluent of the Saône, 20 m. n. of Lyons, on the Paris and Marseilles railway. It is surrounded by a district studded with charming country-seats, and consists chiefly of a handsome street a mile and a quarter in length. Manufactures of cotton goods are carried on, and there is a great trade in wines, horses, cattle, hides, and cloth. Pop. (commune) '91, 12,928.

VILLEIN. See SERF.

VILLÈLE, JEAN BAPTISTE SÉRAPHIN JOSEPH, DE, 1773–1854; b. Toulouse, France; entered the navy, and made a fortune in the colonies. After being mayor of Toulouse, and representing that city in the deputies, he was appointed minister of finance in 1821. The next year he was given the title of count and made president of the council and minister of foreign affairs. During his administration, but against his will, an expedition was sent to Spain to restore Ferdinand VII. in 1823. He was in high favor with Charles X., whom his ultramontane and extreme royalist policy helped to dethrone. He made the Haytians pay 150,000,000 francs for their independence, and reduced the interest on the public debt; but his reactionary measures, his restrictions on the press, and his partiality for the Jesuits led to his retirement from the ministry in Jan., 1828.

VILLEMAIN, ABEL FRANÇOIS, a distinguished French scholar and writer, b. at Paris, June 11, 1790, and educated at the lycée Impérial (now the lycée Louis-le-Grand). In 1810 he was appointed extraordinary professor of rhetoric at the lycée Charlemagne; and shortly after, maître de conférences de littérature Française et de versification Latine, at the école Normale. During the years 1812–16 three of his literary essays were crowned by the French academy—the *Eloge de Montaigne, Avantages et Inconvénients de la Critique*, and *Eloge de Montesquieu*. In 1816 he was appointed to a chair of modern history at the Sorbonne, as assistant to Guizot; but, in the course of the same year, was transferred by Royer-Collard to the chair of eloquence, which he held till 1826. In 1819, he published in 2 vols. his *Histoire de Cromwell d'après les Mémoires du Temps et les Recueils Parlementaires*—a work written in a calm, liberal, and wise spirit. Louis XVIII. took notice of the author, and Villemain was induced to enter on a political career. The post assigned to him was rather a delicate one, that of chef de l'imprimerie et de la librairie. Under the ministry of M. Decazes, he also held the office of maître des requêtes to the council of state, and in 1820 was decorated with the legion of honor. Two years later appeared his translation (with preliminary essay and notes) of the *Republic* of Cicero; and in 1825, a drama entitled *Lascaris, ou les Grecs du XV. Siècle*, and an *Essai sur l'Etat des Grecs depuis la Conquête Musulmane*. In 1827, having gradually passed over to the ranks of the liberal opposition,

he was charged, along with Lacretelle et Chateaubriand, to draw up the petition addressed by the French academy to Charles X. against the re-establishment of the censorship of the press! The result of this hardihood was the loss of his appointment as maître des requêtes, and, in consequence, a vast increase of his popularity as a lecturer at the Sorbonne. In the beginning of 1830 he was sent to the chamber of deputies by the electoral college of Evreux, took his seat among the liberal party, signed the famous address of the 221, and was altogether very prominent and active in those movements which brought about the constitutional monarchy of Louis Philippe. But he was too sober, unsympathetic, philosophical a politician, too much a *doctrinaire* of the Guizot school, to be a favorite with the excitable masses, and he only sat in the chamber for one year. In 1831 the king named him member of the royal council of public instruction, of which he became vice-president in 1832. The same year witnessed his elevation to the peerage. Villemain held the portfolio of public instruction in the ministries of Soult (1839–40) and Guizot (1840–44); but his health failed under the immense labors of his department, and the impossibility of pleasing so many different parties—the church, the university, the reds, the liberals, the doctrinaires, and the king himself; and, in consequence, he found it necessary to resign. Afterward, Villemain wisely devoted himself to literature alone. His principal works are: *Cours de Littérature Française; Tableau du XVIII. Siècle; Discours et Mélanges Littéraires* (1823); *Nouveaux Mélanges Historiques et Littéraires* (1827); *Etudes de Littérature Ancienne et Etrangère* (1846); *Tableau de l'Eloquence Chrétienne au IV. Siècle* (2d ed. 1849); *Etudes d'Histoire Moderne* (1846); *Souvenirs Contemporains d'Histoire et de Littérature* (1856); *Choix d'Etudes sur la Littérature Contemporaine* (1857); *La Tribune Contemporaine, M. de Chateaubriand* (1857); *Essais sur le Génie de Pindare et sur la Poésie Lyrique* (1859); besides a vast number of essais, etudes, discours, notices, and rapports, addressed to the French academy, of which he was perpetual secretary from 1832. Villemain's elaborate *Histoire de Grégoire VII.*, nearly finished at the time of his death, was published in 1872. Villemain died May 8, 1870.

VILLEMESSANT, Jean Hippolyte de, b. France, 1812; resided some time in Tours and Nantes; settled in Paris as a journalist, 1840; established the *Sylphide*, and wrote fashion articles for the *Presse;* was connected with several papers in 1848, which were suppressed; founded the *Chronique de Paris,* 1850; revived in 1854 the *Figaro* as a weekly and semi-weekly journal, to which Edmond About, Rochefort, and Henry de Péne contributed. In 1866 he issued a daily, whose circulation in 1870 amounted to 70,000. He published *Memoires d'un Journaliste.* He d. 1879.

VILLE'NA, a t. of Spain, in the modern province of Alicante, and 37 m. n.w. of the city of that name by railway. The streets are narrow and winding, and are overlooked by an old castle, which has an imposing appearance, owing chiefly to its elevated position. Around the town, the hills are clad with vines, and the country is fertile. It has numerous distilleries, and manufactories of soap and linen. A great fair takes place here every autumn. Pop. '87, 14,450.

VILLENEUVE, Pierre Charles Jean Baptiste Sylvestre de, Vice-Admiral of France, descended from an ancient and noble family, which has supplied an almost uninterrupted succession of distinguished ornaments to their country, was born at Valensoles, in the department of Basses-Alpes, Dec. 31, 1763, entered the navy in his 15th year, and passed as capt. in 1793. In 1796 he was raised to the rank of "capt. of division" (equivalent to *commodore* in the British navy), commanded the rear-division at the battle of the Nile, and after that disastrous fight, succeeded in carrying off to Malta his own vessel, the *Guillaume Tell,* and four others. In 1804 he was nominated vice-admiral; and in the following year was appointed to the command of the Toulon squadron, with which he succeeded in reaching Cadiz, where he was joined by the Spanish fleet under Gravina. His orders being to attempt the withdrawal of the British fleet from the coasts of Europe, he bore away westward across the Atlantic, reaching the Antilles on May 14, and there making a number of valuable captures. A month afterward, hearing that the British fleet had reached Barbadoes, he at once re-embarked his troops, and returned to Europe, pursued by Nelson. On reaching the Azores, however, he encountered a British squadron, under sir Robert Calder, and a fierce combat ensued, which lasted till dark. On the following morning, neither side cared to renew the engagement (for which Villeneuve was abused by *Le Moniteur*, and Admiral Calder was put on trial), and Villeneuve, unable to reach Brest, again returned to Cadiz, where he was strictly blockaded by Nelson. The unjust severity with which he was treated by Napoleon arose from the fact, that the battle off the Azores, and the subsequent blockade of the French and Spanish fleet in Cadiz, had completely ruined Napoleon's scheme for the invasion of England; and the further indignity of being superseded hurried the unfortunate Villeneuve into the desperate resolve of engaging Nelson before his successor could arrive at Cadiz. Besides, by a stratagem of Nelson, he was led to believe that the strength of his enemy was such as to afford him a favorable opportunity of wiping out the disgrace of his former failures, and he accordingly, in superior force, sallied out of the harbor, and engaged in the memorable conflict of Trafalgar (see Trafalgar, and Nelson). A passage in the instructions issued to his captains on Oct. 20 sufficiently

shows the irritated state of his feelings—"Every capt. who is not under fire is not at his post, and a signal of recall will be a brand of dishonor to him." Villeneuve, whose vessel the *Bucentaure*, was completely dismasted, was forced to strike his flag, and was made prisoner, and conveyed to England, whence he returned to France in April, 1806. Instead of rendering himself at Paris, he stopped at Rennes, with the view of ascertaining the kind of reception he was likely to meet with from the emperor. The result of his inquiries was unfavorable; and on the morning of April 22 he was found dead in bed, with six knife-wounds in his heart. He had died by his own hand.

VILLENEUVE D'AGEN, or VILLENEUVE-SUR-LOT, a t. of France, in the department of Lot-et-Garonne, in a charming valley, 15 m. n. of the town of Agen. The river Lot divides it into two unequal parts, communicating by a remarkably bold bridge of a single arch, which, together with portions of the ramparts, remained standing when the town, formerly called Gajac, was destroyed in the wars of the commencement of the 13th century. A great trade is carried on in wines, prunes, cattle, and iron; there are manufactures of paper, cloth, table-linen, and copper wares. Pop. (commune), '91, 13,798.

VILLERS, CHARLES FRANÇOIS DOMINIQUE DE, 1765–1815; b. France; served in the French artillery. He opposed the revolution, became a resident of Lübeck in 1797, and endeavored to familiarize Frenchmen with the best works in German philosophy and literature. He was exiled from Lübeck on account of his book relating the outrages by the French when they took that city. He was afterward a professor at Göttingen. Among his works are: *La Philosophie de Kant* (1801); *Essai sur l'Esprit et l'Influence de la Reformation de Luther* (1804).

VILLIERS, GEORGE WILLIAM FREDERICK. See CLARENDON, EARL OF.

VILLOISON, JEAN BAPTISTE GASPARD D'ANSSE DE, 1750–1805; b. France; went to Venice in 1778, commissioned by the government to look for unpublished Greek manuscripts in the library of St. Mark, where he found an *Iliad* MS. of the 10th c., which he published in 1788. His *Anecdota Græca*, also containing results of his search at Venice, appeared in 1781. In 1783 he printed *Epistolæ Vimarienses.*

VILNO (often written VILNA), a government of west Russia, bounded on the w. by Poland, from which it is separated by the Niemen, and on the e. by the government of Vitebsk, from which it is separated by the western Dwina, and by that of Minsk. Area, 16,421 sq.m.; pop. '96, 1,594,809, mostly Lithuanians, Slavonians, Jews, and Tartars. Only 18 per cent of the whole population are Poles. The rivers are the Vilia, Beresina, affluents of the Niemen, and the Disna, which flows n. into the Dwina. The surface is flat; the highest part being only 1100 ft. above sea-level. The soil, in some places very fertile, consists for the most part of clay and sand. Marshes abound, and there are 400 small lakes. The woods which cover the marshes are the great source of the wealth of the government. The principal trees are fir and pine, and the timber is floated down the Niemen and Dwina for export, and used in the interior for ship-building, etc. The climate is mild. There are a good many manufactories in the government; but agriculture is the principal occupation of the inhabitants, and fairs are numerous and important.

VILNO, an important city of west Russia, capital of the province of the same name, picturesquely situated on the Vilia, 473 m. s.w. of St. Petersburg. Besides its cathedral, it is remarkable for the number of its religious edifices, among which are a mosque, several synagogues, and Lutheran meeting-houses. It formerly contained a university, founded in 1576, but abolished in 1832. Among existing institutions, the chief are the observatory, medical society, museum of antiquities, and theater. The principal articles of trade are timber and corn. Manufactures are not important. Pop. '97, 159,568.

VIMIEIRA, a small town in the west of the Portuguese province of Estremadura, where Wellington defeated the French under Junot, 1808, Aug. 21st.

VINAGO, a genus of *columbidæ*, the most marked section of that family, having a comparatively stout solid bill, laterally compressed; with a hard, hooked, and inflated tip; the tarsi short, the feet large, and formed for perching or grasping. The species, of which not many are known, are natives of the tropical parts of Asia and Africa.

VINASSE. After all the crystallizable sugar is obtained from beet syrup a molasses remains, which is subjected to distillation, producing rum. Vinasse is the liquor left in the retort at the end of the distillation. If the concentrated Vinasse be subjected to destructive distillation, and the gases condensed, an ammoniacal liquor is obtained, which contains trimethylamine salts—valuable chemical compounds, which by this process are obtained for the first time in any considerable quantity.

VINCA. See PERIWINKLE.

VINCENNES, a commune and market-t. of France, in the dep. of Seine, 5 m. e.s.e. of the Louvre in Paris. In reality, the town is merely a great fortress and barracks, and is famous for its arsenal, and for its school for the practice of shooting. At the latter, the chasseurs de Vincennes, and all the best marksmen of the army, are trained. Pop. '91, 20,358.

Vincennes owes its historical importance to its castle and park. The chateau, the main object of interest in the town, is rectangular in shape, and dates from the middle of the 14th century. It was surrounded by nine towers, which were in existence down

to the the year 1808, but of which only one, known as the Donjon de Vincennes, 170 ft. high, and with walls 17 ft. thick, remains. The original building dates from the reign of Louis VII., and had its origin in a hunting-lodge, erected here by that sovereign in 1137. Philippe-Auguste enlarged it, and stocked its woods with wild animals, sent to him by the king of England. Here queen Jeanne (wife of Philippe le Bel), Louis le Hutin, and Charles le Bel, ended their days. Philippe de Valois caused the old mansion to be demolished, and laid the foundations of the more modern chateau, which, from the middle of the 14th c. till the time of Louis XV., was a royal residence, and the birthplace and place of death of many princely personages. After this time it was used as a prison, and among the famous men who have languished within its donjon, may be mentioned Henry IV., the prince of Conde, Cardinal de Retz, Mirabeau—who here wrote his translation of Tibullus—and the duc d'Enghien, who was shot in the moat of the castle by order of Bonaparte. There are extensive barracks, known as the New Fort, built 1848–52, and a salle d'Armes, with a large collection of all sorts of weapons. In the center of the Bois de Vincennes, a large tract has been cleared as an exercise ground for troops, and for rifle and artillery practice.

VINCENNES, city and co. seat of Knox co., Ind.; on the Wabash river, and the Baltimore and Ohio Southwestern, the Cleveland, Cincinnati, Chicago, and St. Louis, the Evansville and Terre Haute, and the Pennsylvania Co.'s railroads; 58 miles s. of Terre Haute. A French fort was built here in 1702; the British gained possession in 1763, Virginia in 1779, and the United States in 1783; the city was the capital of Indiana in 1800–13; and received a city charter in 1856. It is the oldest settlement in the state. The city contains Vincennes university, St. Francis Xavier cathedral, St. Rose academy, city and cathedral libraries, high school, St. Vincent's orphan asylum, orphans' home, Harrison park, attractive railroad and highway bridges, and, near by, several fine specimens of Indian mound-building. There are gas and electric lights, electric street railroads, several national banks, about 15 churches, and manufactories of sewer pipe, stoves, jewelry, plows, paper, carriages, and wagons, flour, and foundry, machine shop, and wood-working products. Pop. '90, 8853.

VINCENNES, Jean Baptiste **BISSOT**, Sieur de, 1688–1736; b. Quebec. He was very active in the Indian troubles of the time. In 1704 rescued some Iroquois from a band of Ottawas, who had taken them prisoners, contrary to treaty stipulation, and thus prevented a general war. In 1712 he was engaged in contests with the Fox Indians near Detroit, and about the same time founded the town which bears his name. In 1736 he had command of an expedition against the Chickasaws, was defeated, and with Father Senat, D'Artagnette, and others, was burned at the stake.

VINCENT, John Heyl, D.D., was b. in Tuscaloosa, Ala., in 1832; educated at Lewisburg academy and at Wesleyan institute; and entered the Methodist Episcopal Church. In 1865 he established the *Northwest Sunday-School Quarterly* at Chicago, and in 1866 the *Sunday-School Teacher;* and in 1868–84 had the direction of the Sunday-school work of his denomination. He was one of the founders of the Chautauqua assembly and chancellor of the Chautauqua university from its organization. In 1888 he was elected bishop. He wrote several volumes for the Chautauqua text-book series.

VINCENT, Marvin Richardson, D.D., b. Poughkeepsie, N. Y., 1834; graduated at Columbia coll., N. Y., 1854; was first classical instructor of the grammar school of Columbia coll., 1854–58; prof. of Latin, Troy univ., 1858–62; pastor of the First Pres. church, Troy, N. Y., 1863–73; of the church of the Covenant (Pres.), N. Y., 1873–88; and became a professor in Union theolog. seminary, New York, 1888. He published a translation of Bengel's *Gnomon of the New Testament*, with Dr. Charlton T. Lewis (1862); *Amusement, a Force in Christian Training* (1867); *The Two Prodigals* (1876); *Gates into the Psalm Country* (1878); *Stranger and Guest* (1879); *Faith and Character* (1880); *The Minister's Handbook* (1882); *In the Shadow of the Pyrenees* (1883); *The Expositor in the Pulpit; God and Bread* (1884); *Word Studies in the New Testament* (1889); *Biblical Inspiration and Christ*, and *That Monster, the Higher Criticism* (1895); *The Age of Hildebrand* (1896); *Philippians and Philemon* (1897), etc.

VINCENTIAN CONGREGATION, so called from its founder, the Roman Catholic saint, Vincent de Paul, is an association of secular priests, who, although not in the strict sense a religious order, are bound by vows, and are especially devoted to the duty of preaching and hearing confessions among the people, particularly the poor. Another object of the Vincentian congregation is to undertake the direction of episcopal seminaries and other colleges for the education of ecclesiastics, as also to direct the annual devotional exercises of the secular clergy, called ecclesiastical retreat. See Paul, Vincent de. At the latest recorded enumeration which has come under our notice, the congregation numbered above 700 members, in France, Italy, Poland, the Levant, and Algeria. The members are numerous also in America, and branches exist in Ireland and Scotland. The name Vincentian is sometimes given also to the sisterhoods (of which there are several, and of which that of charity is the most remarkable), which were founded by Vincent de Paul, and even to the charitable lay association, better known as the society of St. Vincent de Paul, which has extensive ramifications in almost all the countries in communion with the church of Rome, and which has been the occasion of certain recent restrictive measures in France.

VINCENT, SAINT. See Saint Vincent.

VINDHYA MOUNTAINS. See India.

VINE, a term sometimes used to designate any climbing plant, especially if shrubby, but also more particularly applied to the species of the genus *vitis*, of the natural order *vitaceæ*. This genus has *pentamerous* flowers (5-toothed calyx, 5 petals, 5 stamens), and has the petals united into a kind of hood and deciduous. The most important species is the GRAPE VINE (*V. vinifera*), from the fruit of which wine and raisins are made. The name grape is from the French *grappe*, a bunch of grapes; from the same root as *gripe* or *grab*, to grasp.

The grape vine has large, angular, lobed, toothed, and more or less hairy leaves. The stems are numerous and branching, very long, and of rapid growth, with many tumid joints, the outer bark readily splitting and peeling off, the woody tissue abounding with vessels of large size, from which at the seasons of active vegetation, if the branch is wounded or cut across, the sap pours in prodigious quantity. The fruit-stalks, which are much branched, are opposite to the upper leaves, or in their stead are tendrils. The flowers are small, greenish white, and fragrant. The fruit is a round or oval berry, 2-celled and 4-seeded, varying much in size and color—in the small Corinth or currant grape, about ¼ of an inch in diameter; in the largest varieties, more than half an inch; green, yellow, red, purple, and sometimes variegated; but the color is entirely in the outer skin, the juice being always colorless; and while the pulp of the grape is wholesome, nutritious, and gently laxative, the skin is astringent and indigestible. Some of the ovules are often abortive, or even all of them in the fruit of old vines of some varieties, as in the seedless Ascalon or Sultana raisins.

The vine attains a large size, the stem being sometimes 18 inches in diameter, so that the wood, which is very hard and durable, has been employed for making furniture, statues, etc. It attains also a very great age, continuing fruitful for at least three or four hundred years.

The grape is one of the most valuable of fruits, not only because of its use in the manufacture of wine, and as the source also from which brandy, vinegar and tartaric acid are obtained, but because, both in a fresh and dried state, it forms not a mere article of luxury, but a great part of the food of the inhabitants of some countries. Dried grapes, under the names of *raisins* and *currants*, are a considerable article of commerce. Fresh grapes are commonly eaten with bread in Syria, and some other countries in which they abound. The usefulness of the grape is increased by its keeping fresh for many weeks in a cool airy place. Some varieties are more easily kept than others. More than 1500 varieties are described in works on the culture of the grape; and this subject, under the name *ampelography* (Gr. *ampelos*, a vine), has been elevated by some recent German writers almost to the rank of a distinct branch of science. The quality of the grape is extremely liable to be affected by circumstances of soil and climate, and this is particularly to be observed in the wine produced from it, the difference between the produce of two vineyards in the same neighborhood being often very remarkable.

The vine dislikes a damp soil, but will thrive in almost any open soil with good drainage. In rich deep soils it grows luxuriantly, and produces abundance of large fruit; but on shallow, dry soils, the fruit, though less abundant, is of finer flavor. The vineyards most celebrated for the excellence of their wines are not generally of rich soil. The steep slopes of hills are often planted with the vine, and are sometimes terraced for this purpose; and nothing can be more suitable to situations where patches of good soil are mingled with bare rocks, nor anything more beautiful than the rocks covered with luxuriant foliage and rich fruit. This mode of cultivation on steep rocky slopes was anciently very prevalent in Judæa.

It is doubted of what country the grape-vine is a native, nor is it known at what time, certainly very remote, its cultivation was first introduced into the s. of Europe. It is now found wild in some parts of Europe, but is rather naturalized than truly native. It seems probable that it is indigenous in the hilly countries on the s. of the Caspian sea, where it is very abundant and luxuriant, climbing to the tops of the loftiest trees, and producing large bunches of delicious fruit. But it is doubted if *vitis Indica*, a native of the n. of India, abounding in some parts of the Himalaya, is really a different species. The wild grapes of these mountains are round and purple, and very agreeable. It is doubted also by some if any of the wild grapes of America are really distinct; some of which, however, are much more different in their characters and qualities from the common form of the cultivated plant. Of these American grapes, the FOX GRAPE (*V. labrusca*) is the most similar to the cultivated grape. It is common throughout great part of North America, and is found as far n. as Quebec. The berries are large, deep blue, with thick skin and tough pulp, but make good wine, and have been found capable of much improvement by cultivation; their color also varying to red and white. The SUMMER GRAPE (*V. æstivalis*), not found n. of lat. 42°, has smaller and more agreeable berries, which are regularly brought to the Philadelphia market. Very similar to this is *V. sinuata*, a native of Virginia and Carolina, from the fruit of which good wine is made. The BULLACE GRAPE (*V. rotundifolia*), found only as far n. as lat. 39°, has larger grapes than any other American species, and of agreeable flavor. There is also a species, the FROST GRAPE (*V. cordifolia*), with small berries, and a variety (*V. riparia*) found abundantly on gravelly banks of rivers in the western states, which has exquisitely fragrant flowers. But the habit and leaves of all these differ very little from those of the common vine. Nor does the WATER WITHE of Jamaica, so called from the great quan-

tity of sap which its shoots pour out when cut (*V. Caribbæa*), differ in very marked botanical characters; although its small black berries, which it produces in immense quantity, are acid and austere.

The cultivation of the grape and the making of wine are of the most remote antiquity, as appears from the Scripture history of Noah, and from many passages of the most ancient authors. The mythological fable of the marches of Bacchus relates to the extension of the culture of the vine from Asia into Europe. The earliest accounts we have of the manner of cultivating the vine are by the Roman authors Virgil and Columella. The vine was probably introduced into the s. of France as early as into Italy; it is said to have been brought to Marseilles by the Phocæans, about 600 B.C., and its cultivation was early co-extensive with civilization in all the countries near the Mediterranean. In Italy, so much of the land was occupied by vineyards, that the emperor Domitian, fearing a scarcity of corn, issued a restrictive or prohibitory edict 81 A.D., which was afterward long continued in force, through fear that the abundance of fine wine might tempt the barbarians of the n. to invade the country. The vine was introduced into the s. of Germany about the 3d c. B.C. Augustus preferred the Rhætian wine to all other. The first vineyards on the Rhine and Moselle were planted by the emperor Probus in 281 A.D. Under the Merovingians, the culture of the vine extended greatly both in France and Germany. Charlemagne derived a very considerable revenue from the vineyards even of the northern parts of his empire. The Huns who remained in a number of settlements on the Rhine, after the expedition of Attila into Gaul, 451 A.D., brought thither the arts of cultivating the grape, and of making wine, from Pannonia; and Hunnish grapes and Hunnish wine were long in particular repute. In the middle ages, the monks were the first to plant vineyards and to make wine in many parts of Europe.

The cultivation of the vine was introduced into England by the Romans. At the time of the Norman conquest, there seem to have been vineyards in the s. and s.w. of England, and, although they afterward disappeared, successful attempts were occasionally made to re-establish them; and one at Arundel castle in Sussex yielded, about the middle of last century, large quantities of wine. Of late years, the cultivation of the vine has much increased in the s. of England, in gardens, on the walls of suburban villas and of cottages, but chiefly for the sake of the fresh fruit, although wine of pretty good quality is also made in small quantities for domestic use.

The vine does not, in ordinary seasons, ripen its fruit well in Great Britain further n. than Yorkshire, although grapes have occasionally ripened in the open air in Scotland. It is, however, a hardy plant, in so far as the endurance of severe winter-frosts is concerned; but it requires for the ripening of its wood, as well as of its fruit, a considerable summer heat continued for several months. Thus, it does not succeed in parts of Britain in which the mean temperature of the year is higher than that of countries where good wine is made. A very moist climate is also unsuitable to it; and therefore it is not extensively cultivated in the n.w. of France, although there are many productive vineyards in the n.e. In the most northern regions to which its cultivation extends, the vine is protected in various ways during winter; in some places, by laying down its branches, and covering them with some depth of earth. It produces abundant fruit in warm climates, such as India, but the juice passes too rapidly into acetous fermentation to be used for making wine, although in many of the mountainous districts of India it might probably be cultivated for this purpose with success. Shiraz, in Persia, is one of the warmest climates celebrated for the production of good wine.

In Europe, the cultivation of the vine forms an important branch of rural economy as far n. as Coblenz on the Rhine; but in some countries, particularly in Greece and the Ionian islands, raisins form the chief part of the produce of the vineyards.

The cultivation of the vine was early introduced by the Spanish and Portuguese into the Azores, the Madeira and Canary isles, and America. The first vines were carried to the cape of Good Hope by the Dutch in 1650; but while the wines of Madeira and those of the limited district of Constantia at the cape of Good Hope have long enjoyed a high celebrity, and those of Canary and Teneriffe have been imported in considerable quantities into Europe, it is only of late that much attention has begun to be paid to the cultivation of the grape in the other parts of Cape Colony, or in any part of America. It is now, however, prosecuted with energy in Ohio, New York, California, and other states of North America, and very good wines are produced. It has also been introduced into Australia, where good wines are made, although not yet to a large extent.

The cultivation of the vine varies much in different countries. Success seems chiefly to depend on a good sunny exposure, liberal but not coarse manuring, and constant attention. New varieties are raised from seed, but the ordinary modes of propagation are by layers and cuttings. Fine varieties are sometimes budded or grafted on less valuable ones. In the vineries of America, the vines are carefully trained, in various ways, so as most completely to cover the walls and trellises, and to turn the whole available space to the utmost account; while superfluous shoots are displaced by pruning, so that the strength of the plant may be directed to the fruit-bearing branches, and that there may be no undue luxuriance of foliage to prevent sufficient access of light and air. The luxuriant growth of the plant renders the frequent application of the pruning-knife necessary during summer. The fruit being produced on shoots of the current year, the pruning is managed with a view to the abundance of these shoots, the greater part of which, when

they have served their purpose, are cut away, such only being left as are required for the extension of the space profitably occupied by the plant. The bunches of grapes are also generally thinned out with great care, in order that finer fruit may be produced.

The first attempt at the culture of the vine in the United States for wine-making was in Florida, in 1564; and another was made by the British colonists in Virginia, in 1620. Early in the 18th century certain vineyards in the latter state produced as much as 750 gallons of wine per annum; and in Delaware, wine was made from native grapes as early as 1648. In 1664 the governor of New York granted to one Saul Richards the privilege of making and selling wine, free of duty. In 1683 William Penn engaged in the cultivation of the vine, near Philadelphia, but with only partial success. In 1790 a Swiss colony made unsuccessful attempts to establish vineyards in Jessamine co., Ky.; and afterwards removed to Vevay, Ind., where they met with better fortune. In Illinois, 110 hogsheads of wine were made from native grapes in 1796; and, near the end of the last century, wine was made in Pennsylvania from the Schuylkill Muscatel grape, which was the same employed in Indiana. In 1825 the Catawba vine, a native of North Carolina, came into prominence; and it was afterwards cultivated extensively near Cincinnati by Nicholas Longworth, who may be called the father of this culture in the United States. In California, viticulture, introduced by the Franciscan fathers, was successful from the beginning, and, how well adapted the soil and climate are, is shown by the fact that a single vine of what is called the Mission variety, planted about 1823 by a Mexican woman, was reported in 1890 to have a diameter, one foot from the ground, of 12 inches, to cover an area of 12,000 feet with its branches, and to bear annually from 10,000 to 12,000 pounds of grapes, many bunches weighing six and seven pounds. One vineyard, in Tehama county, is the largest in the world (4000 acres), and another at Folsom, Sonora county, contains 1500 acres. The first grape planted, the Los Angelos, or Mission variety, was the only one grown until 1820. More than 30 varieties of European grapes, adapted for wine-making, are grown in the open air, including the Black Hamburg, Trousseau, Charbonneau, Herbemont, Berger, Zinfandel, and Malbeck, and the Muscatel de Gordo Blanco, and other raisin grapes. Four-fifths of the grapes grown in New York, Pennsylvania, and New Jersey are used for table purposes. The Lake Keuka, Hudson River, and Chautauqua districts in New York produce the largest amounts. Among the varieties most largely grown are the Concord, Catawba, Delaware, Moore's Early, Niagara, Diana, Worden, and Isabella. In Ohio, the industry is mainly found on the Lake Erie islands and in the counties bordering the lake, nearly all the product going to western markets for table use, the remainder being converted into wine and champagne. The Southern States are taking increased interest in viticulture, and the early grapes of Georgia and Florida reach northern markets several weeks in advance of those from northern and western states. The Niagara is a favorite variety in the south. Missouri vineyards are less productive than formerly. New Mexico and Arizona are assuming prominence in this industry. In New Mexico the Zinfandel, Mataro, Cabernet, Sauvignon, Cabernet Franc, Mission, Petite Piro and Chassolas Fontainebleau are successfully grown for wine, and the Muscat of Alexandria, Muscatel and Sultana for raisins. According to the census of 1890, the grape-growing districts of our country comprised 401,261 acres, of which 307,575 acres were in bearing, producing 572,139 tons, of which 240,450 tons were used for wine, making 24,306,905 gallons; 41,166 tons for raisins, making 1,372,195 boxes of 20 pounds each; and 23,250 tons for dried grapes and purposes other than table fruit. The total value of plant, including land, was $155,661,150, and the laborers employed, 200,780. Only about one person to three acres is directly employed in growing grapes. California had 200,544 acres in vines; New York, 51,000; Ohio, 33,000; Missouri, 11,274; Virginia, 5700; Kansas, 5542, and North Carolina, 5200. The average yield of grapes per acre ranged from three tons in Arizona, Missouri, and New Mexico, to 1.75 in Indiana, New York, and North Carolina, and the market value per ton from $96 in Georgia to $16.50 in Arizona. From our native vines a vast number of varieties have been derived, such as the Catawba, Isabella, and Scuppernong. The Concord is deservedly popular in the Eastern States, because it proves reliable in almost all locations and soils. Among the chief enemies of the vine are fungoid growths, mildew (see Oidium), rot, and the *phylloxera vastatrix*. (See Phylloxera.)

The phylloxera has been most successfully combated in Europe by grafting susceptible vines into stock raised from the seeds of American wild grapes. *V. riparia* is considered the best for this purpose, but *V. æstivalis*, *V. vulpina*, *V. Labrusca*, and other species and varieties are also used. In the United States kerosene emulsion and bisulphide of carbon are efficacious.

The juice of ripe grapes contains a considerable quantity of *grape-sugar* (see Sugar), small quantities of a glutinous substance, and of extractive bitartrate of potash, tartrate of lime, a little malic acid, and other ingredients, suspended or dissolved in water. The rapidity with which it passes into a state of fermentation after being expressed from the fruit is remarkable.

For the making of wine, the wine-trade, the qualities and uses of wines, the different kinds of wine, etc., see Wine. Concerning the other commercial products of the grape, see Brandy, Vinegar, Tartaric Acid, Raisins, and Currants.

VINEGAR is that form of Acetic Acid (q.v.) which is generally preferred for culinary purposes, and which is made by the fermentation of vegetable substances. In the U. S. it is manufactured on a large scale from the so-called hard cider; on the continent of Europe, it is as largely made from low wines which have turned sour Malt, or British vinegar, as it is sometimes called, is made by brewing a weak wort from malt exactly as for beer (q.v.). To 100 gallons of this, at a temperature of 70°, are added 4 gallons of yeast, and well stirred through for 8 or 10 minutes. This mixture is then allowed to ferment actively for two days, and is then transferred to the stoving-room; here it is distributed into a number of tubs, which. when filled, are covered over with a coarse canvas. This room is dark, and is heated by stoves, and the heat is constantly sustained for weeks until the conversion of the wort into vinegar is complete. The process of acetification is accelerated by introducing into the casks with the wort either the residuary fruit used in making domestic wine, or the foot stalks and skins of grapes. This *rape*, as it is called, acts as a kind of ferment. Other processes are used by different manufacturers for the purpose of producing it quicker; but the minute descriptions necessary to render them clear would be out of place here. Much vinegar is also made of beer which has become sour; it is, however, very inferior in quality, and wants the agreeable flavor of malt vinegar prepared by the above process, which is due to the presence of acetic and other ethers.

A rather insipid kind of vinegar is made by means of the vinegar-plant (q.v.). The vinegar-plant itself may be produced thus: A solution of a quarter of a pound of sugar and half a pound of treacle in three quarts of water is first simmered, then poured into a jar, covered up, and kept in a warm place for six weeks. The liquid becomes vinegar, and on the top there has been formed a scum-like fungus, which is the vinegar-plant; and by adding a piece of this to a similar solution, the process of conversion into vinegar now takes place in much less time. During the process, the plant thickens by the formation of a new layer on its under surface; and by peeling off this layer, and using it in a fresh operation, the plant may be propagated indefinitely.

The greatest manufacture of *wine vinegar* in Europe is at Orleans, in France. Here the wines are sent from all parts when unfit for drinking, and are converted into vinegar. In the manufacture a large number of casks are used, with openings into each of only two inches diameter. Into each one are poured 100 pints of vinegar boiling hot; and to this, after eight days, are added 10 pints of sour wine, and this is repeated every 8 days until the cask is full; another 15 days completes the process, and the vinegar is ready for use. Beech-shavings are much used in vinegar-making, as they are found to assist in clarifying the liquor by attracting the lees, which settle upon them, and leave the liquor clear, in which state it acetifies more rapidly.

"According to Ure, a good vinegar may be prepared by adding to each gallon of a syrup composed of 1¼ lb. of sugar and 1 gal. of water, a quarter of a pint of yeast. If kept for three days at a temperature of 75° or 80°, it will be sufficiently acidified to allow of being drawn off into the refining-cask, where one ounce of bruised raisins and one ounce of crude tartar are to be added to each gallon of liquor. When the sweet taste has quite disappeared it should be drawn off into bottles, and corked down tightly. It is stated that such vinegar will contain 5 per cent of pure acetic acid."—Miller's *Organic Chemistry*, 2d ed. p. 339. Vinegar prepared by these methods contains a large amount of foreign matters, which can be got rid of by simple distillation; the acid liquid which comes over constituting what is known in pharmacy as *distilled vinegar*. What is sold commercially as distilled vinegar is simply ascetic acid distilled from wood (See Pyroligneous Acid), and diluted with five times its volume of water. This constitutes also the vinegar used by pickle manufacturers; it is quite as wholesome as common vinegar, but wants its agreeable flavor; its preservative powers are, however, much greater, and its price very much less, if fairly charged. Vinegar containing five per cent of the pure acid is the strongest that is ever produced, and is termed *proof vinegar*. There are four kinds manufactured, which are known in trade by the numbers 18, 20, 22, and 24, the last being the best quality. The strength of any specimen is best ascertained by determining the quantity of anhydrous carbonate of soda which a given weight of it will neutralize, it being recollected that 100 grains of carbonate of soda correspond to 96.2 grains of anhydrous acid. The ammonia test, according to Neligan, serves to distinguish French from English vinegar: with the former, the color is purplish; with the latter, there is either no change, or it is brownish. There is generally a slight turbidity, which is due to a trace of lime.

As a condiment, vinegar is an ingredient of a large number of sauces, and of all ketchups and pickles; and although it cannot be regarded as an essential article of food, its applications in cookery are numberless. Young ladies, with an undue tendency to corpulency, sometimes drink vinegar freely with the view of improving the figure; but as vinegar only causes thinness by injuring the digestion, it is obviously not worth while that they should run the risk of exchanging slight fullness of habit for chronic dyspepsia.

Vinegar is used in medicine as a cooling astringent, and may be employed with much benefit if taken freely, when largely diluted with water, in hemoptysis, in hematemesis, and in the colliquative sweating of hectic fever. Dr. Neligan states that in severe hiccough, he has often seen benefit derived from a dose of a wine-glassful of vinegar. In cases of poisoning with the alkalies or their carbonates, it is one of the best antidotes.

It may also be employed locally in various ways—as, for example, to check hemorrhage from the nose, womb, etc. In intestinal hemorrhage, an enema containing vinegar and cold water may be used with success, especially if the lower part of the intestine be the seat of the bleeding. Sponged in a diluted state (one part to three of cold or tepid water) over the neck, chest, etc., it affords great comfort and considerable relief in cases of colliquative sweating. In its character of a refrigerant rather than as an astringent, its local action on the skin is attended with much benefit in the treatment of most febrile and inflammatory diseases; it should be freely applied, as in colliquative sweats, to the surface of the body, face, and extremities; and thus employed, has a very tranquillizing effect, and often induces sleep. The heat and pain commonly experienced in sprains are often relieved by the local application of brown paper soaked in diluted vinegar, and changed when the feeling of heat returns. It is an important addition to astringent gargles in cases of relaxed uvula and tonsils; and is the best application to the eyes in cases in which lime has got within the eyelids. The ordinary dose is from 2 to 4 drams; and when taken as a drink, 3 ounces may be mixed with a pint and a half of water, and taken in the course of the day.

The term *Chili vinegar* is applied to a preparation obtained by infusing half an ounce of cayenne pepper in a quart of French vinegar for ten days, and straining. It is commonly added to gargles in the proportion of 1 ounce to 8 or 9 ounces of infusion of roses, in cases of relaxed sore throat.

Aromatic Vinegar, known also as *Vinegar of the Four Thieves*, *Marseille Vinegar*, and *Camphorated Vinegar*, and *Camphorated Acetic Acid*, consists of strong acetic acid, holding in solution camphor and the oils of cloves, lavender, rosemary, and lemons. It is very fragrant and volatile, and must be kept in well-stoppered bottles. It was formerly regarded as a valuable prophylactic of all infectious diseases, but is now only used as an external stimulant, the vapor being applied by a smelling-bottle to the nostrils in cases of fainting.

VINEGAR-PLANT, *Pencillium glaucum*, a fungus of the sub-order *hyphomycetes*, but somewhat resembling those known by the name of Mould (q.v.). It forms a flocculent mass or web, which is tough and crust-like or leathery, and when examined by the microscope, is seen to consist of a *mycelium* of branched threads, with the branches somewhat tangled, and the spores disposed in patches about the pencil-shaped ends of fertile threads. It is found on decaying bodies and in fluids undergoing the acetous fermentation which it greatly promotes, and which, indeed, it very readily occasions, a small piece placed in sugar and water soon changing it into vinegar. Advantage is sometimes taken of this property for making vinegar.

VINELAND, a borough in the township of Landis, Cumberland co., N. J.; on the Central of New Jersey and the West Jersey and Seashore railroads; 10 miles e. of Bridgeton, 35 miles s.e. of Philadelphia. It is regularly laid out on a plot 1 m. square. The principal avenues are 100 ft. wide; the other avenues and streets 66 ft.; and are bordered with shade trees. The houses are surrounded by vineyards, orchards, and flower gardens. The tract in which is the borough covers an area of 48 sq. miles. It was purchased in 1861 by Charles K. Landis, and is divided into fruit farms of 5 to 25 acres. It lies chiefly in the township of Landis, Cumberland co., but extends to Buena Vista, Atlantic co., and Franklin, Gloucester county. Among the noteworthy buildings and institutions are the New Jersey training school for feeble-minded children, the New Jersey home for feeble-minded women and children, college of the Sacred Heart, public park of 20 acres, and the Vineland historical society. There are national and state banks, over a dozen churches, waterworks, gas lighting plant, central high school, several public and private schools, a kindergarten, and daily, weekly, and semi-monthly periodicals. The distinctive industry is fruit-growing. There are also manufactories of shoes, pearl buttons, chenille, rugs, glass, iron and brass foundry products, machine work, and saw mill products. The sale of intoxicating liquor is prohibited. The climate here is singularly mild in the winter, and favorable for invalids. Pop. '90, 3822.

VINES, Richard, about 1585–1651; b. England. In 1616, or about that time, he established a settlement at Saco Bay, Me., acting as the agent of sir Ferdinando Gorges. In the pestilence of the winter of 1616–17, his medical skill was of great aid to the Indians. In 1617 he ascended the Saco river as far as Crawford's Notch. The village of Biddeford was founded on land granted to Vines by the Plymouth company in 1629.

VINET, Alexandre-Rodolphe, Swiss divine and author, was b. at Lausanne, June 17, 1797, and received his education in his native city as a student of the Protestant church, of which he was ordained a minister in 1819. From an early age he showed a passionate fondness for the study of French literature, which he cultivated with so much success that at the age of 20 he was appointed professor of French language and literature in the gymnasium of Basel. This position he held till 1837, when he removed to Lausanne to fill the chair of practical theology in the academy of that city, which chair, however, he resigned in 1840, when he seceded from the national church, on account of the new constitution imposed upon it in that year. Notwithstanding his resignation, he appears to have continued his lectures either in the academy or privately; and in 1844 again connected himself with that institution as substitute-professor of French literature. Vinet took a leading part in the formation of a constitution for the Free church of Vaud, formed by those who seceded from the national church in

1845, this secession having been in a great measure the result of the influence of his own writings and teachings in favor of the separation of church and state. He died May 14, 1847. Vinet was an eloquent and earnest preacher, clear and brilliant rather than profound in thought; and although highly evangelical and orthodox, advocated the utmost liberty and toleration of opinion and practice in matters of religion. He wrote largely both on literature and religion, and most of his works have been translated into English. His works on French literature show that he was thoroughly acquainted with its history, and possessed the critical faculty in no mean degree; as a philosophico-religious writer, he is very popular among the educated religious public both in England and America. His principal works are: *Chrestomathie Française* (3 vols. 1829); *Histoire de la Littérature Française au XVIII. Siècle; Etudes sur la Littérature Française du XIX. Siècle* (3 vols.); *Mémoire en Faveur de la Liberté des Cultes* (1826); *Discours sur quelques Sujets Religieux* (1831); and *Nouveaux Discours*, etc. (1841)—from which two last-mentioned works selections have been translated into English, and published under the title of *Vital Christianity; Etudes sur Blaise Pascal, Études Evangéliques*, and *Nouvelles Etudes Evangéliques*, which have been rendered into English as *Gospel Studies;* etc.

VINEYARD SOUND, a passage 20 m. long and 6 m. wide between the Elizabeth Islands, off the s.e. coast of Massachusetts and the island of Martha's Vineyard; the customary course for vessels sailing from Boston to southern ports.

VINGT-ET-UN (Fr., "twenty-one") is a game played with a complete pack of cards and any number of persons. It consists mainly in endeavoring to get cards whose spots will aggregate twenty-one. Each member of the party deposits an equal stake in the pool, and two cards are dealt, one at a time, to each player. A twenty-one found in hand after the second deal is called a *natural vingt-et-un*, and, if the company has previously so decided, entitles the holder to deal and double stakes from all. In case of the absence of a natural *vingt-et-un* each player in turn calls for a card, and continues to do so until he holds in his hand a combination making twenty-one, or some number near but below it; a player going beyond twenty-one subjects himself to the forfeiture of his stake; it is therefore wise to *stand*, or cease to call for cards at seventeen. Frequently the entire pack is dealt, the winner of the game being he who holds the number twenty-one or that nearest to it.

VINIC ACIDS, an important group of acids, whose mode of formation may be thus described: When a mixture of concentrated sulphuric acid with any of the alcohols is heated to about 212° F. (100° C.), chemical action takes place, and the result is the formation of a new coupled or conjugated acid, in which the radical of one molecule of the alcohol takes the place of one atom of hydrogen in the sulphuric acid. In these compounds, the existence of sulphuric acid can no longer be detected by the addition of baryta; the new acids forming soluble baryta-salts. They are, in fact, not acids, but *acid salts*. The most common example is *sulphovinic acid*, $C_2H_5 \cdot HSO_4$, now called ethyl hydrogen sulphate. As its formula shows, it is comparable to acid sodium sulphate, $NaHSO_4$, the Na being replaced by the radical ethyl.

VINLAND—i.e., WINELAND—the name given to the chief settlement of the early Norwegians in North America. It is undoubtedly represented in modern times by part of Massachusetts and Rhode Island. The first that saw it was Bjarne Herjulfson, who was driven thither by a storm in the summer of 986 A.D., when making a voyage from Iceland to Greenland, of which country his father, Herjulf, and Eric the Red were the earliest colonists. But Bjarne did not touch the land, which was first visited by Leif the Lucky, a son of Eric the Red, about 1000 A.D. The latter built a number of wooden houses, which were called *Leifsbúdir* (Leif's bothies?). A German of the name of Tyrker, who accompanied him, noticed the grape growing there, as in his native country, and hence Leif called the region "Vinland." Two years after, Leif's brother, Thorwald, arrived, and in the summer of 1003 led an expedition along the coast of New England, southward, but was killed the year following in an encounter with the natives. The most famous of the Norwegian explorers, however, was Thorfinn Karlsefne, an Icelander, who had married Gudrid, widow of Thorstein, a son of Eric the Red, and who in 1007, sailed from Greenland to Vinland with a crew of 160 men, where he remained for three years, and then returned, after which no further attempts at colonization were made. Rafn (q.v.), in his *Antiquitates Americanæ*, has published the most complete collection of the evidence which proves the pre-Columbian colonization of America. See Wilhelmi's *Island, Heitramannaland, Grönland und Vinland* (Heidelberg, 1842). Both Rafn and Finn Magnusen are excessively anxious to show that Columbus derived his first hints of a new world from the accounts of these old Icelandic expeditions. Their *amor patriæ* perhaps leads them too far; but, on the other hand, it is well to bear in mind that Finn Magnusen, in one of the early numbers of the *Nordisk Tidsskrift for Oldkyndighed* has conclusively established the fact that Columbus did visit Iceland in 1477, 15 years before he undertook his great expedition across the Atlantic; and it is not at all improbable that he may have heard, while there, something of the long-abandoned Vinland. See Nordenskiöld in *Nature*, vol. xxviii.

VINNITZA, a t. of west Russia, in the province of Podolia, stands on both banks of the Bug, 100 m. e.n.e. of Kaminetz. It was founded in the 14th c., and has suffered much from the invasions of Tartars and the Cossacks. There were, in 1891, 13 factories,

5 Russian, and one Catholic church, and 13 synagogues. Pop. '91, 24,989, of whom 58% were Jews.

VINTON, a co. in s. Ohio, drained by Raccoon and Salt creeks; 402 sq.m.; pop. '90, 16,045. Co. seat, McArthur.

VINTON, Alexander Hamilton, d.d., 1807–81; b. Providence, R. I.; studied at Brown university; graduated at the Yale medical school, 1828; practiced medicine, 1828–32; studied theology at the General Episcopal seminary, New York; ordained, 1835; pastor of a church, Portland, Me., 1835–36; at Providence, R. I., 1836–42; at Boston, 1842–58; rector of Holy Trinity, Philadelphia, 1858–61; rector of St. Mark's church, New York, 1861–70; rector of Emanuel church, Boston, 1870; professor in the Protestant Episcopal divinity school, Cambridge, Mass. Dr. Vinton was an eloquent pulpit orator, a ripe scholar, and a faithful minister.

VINTON, David H., 1803–73; b. R. I.; graduated at West Point, 1822; entered 4th artillery; was sent to Florida, 1836; quartermaster-general of Florida, 1837–46; chief quartermaster on the staff of Gen. Wool in Mexico, with rank of major, 1846; chief quartermaster in department of the west, 1852–56; of Texas, 1857–61; taken prisoner when Twiggs surrendered; exchanged, and became chief quartermaster, New York; made colonel, 1864; assistant quartermaster-general, 1866; placed on retired list the same year; was brevetted colonel and brigadier-general for faithful service.

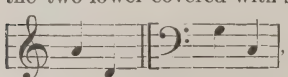
VINTON, Francis, d.d., 1809–72; b. R. I.; graduated West Point, 1830; second lieutenant 3d artillery; stationed at fort Independence, Boston; studied law at Harvard law school; civil engineer on several New England railroads two or three years; admitted to the bar, 1834; studied theology at the Episcopal theological seminary, New York, 1836; ordained 1838; rector at Providence and Newport, 1840–44; Grace church, Brooklyn, N. Y., 1844–55; assistant minister of Trinity church, New York, 1855; prof. of ecclesiastical law and polity in the General theological seminary, 1869. He published *Arthur Tremaine*, or *Cadet Life; Manual Commentary on the General Canon Law of the Protestant Episcopal Church in the United States.*

VINTON, Francis Laurens, b. Maine, 1835; graduated West Point, 1856; entered the cavalry, but resigned, to devote himself to metallurgy; became pupil of the Imperial School of Mines at Paris, graduating with distinction; appointed capt. of the 16th U. S. infantry, 1861; col. 43d regiment of N. Y. volunteers; fought in Hancock's brigade through the peninsular campaign; made brig.gen. of volunteers, Mar. 1, 1863; wounded at Fredericksburg; prof. of mining engineering, Columbia college, 1864. D. 1879.

VINTON, Justus Hatch, 1806–58; b. Conn.; educated at Hamilton institution, (now Colgate university); sailed as missionary of the American Baptist missionary union for Burmah in 1834; was stationed among the Karens at Chummerah, 90 m. from Moulmein; visited the United States in 1851, and returning took charge of the Karen theological seminary at Moulmein, but removed the following year to Rangoon, continuing his labors among the Karens.

VIOL (Mid. Lat. *vitula;* Ital. *viola*, derivation uncertain), a musical instrument played with a bow, no longer in use, which was the immediate precursor of the violin. It is to be seen represented on monuments as far back as the close of the 11th century. The belly and back were flat; there were larger bends in the sides than in the violin; and frets, like those of the guitar, were placed on the neck of the instrument, to show where the fingers of the left hand should be put to produce the desired notes. There was great variety in the number of strings: in Germany, 3, 4, and 5 were all common; in Italy, there were usually six. The strings were tuned by fourths and thirds. There were 4 sizes of viol in use for treble, alto, tenor, and bass respectively, and they were often played together in concerted music. The smaller viols were called *viol da braccio*, from being held with the arm; the larger, *viol da gamba*, from being placed between the legs. The treble viol was rather larger than the modern violin. The viol da gamba, or bass viol, held its place longer than the smaller viols, but was eventually superseded by the violoncello.

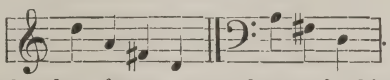
VIO'LA, Alto Viola, or Tenor Violin, a larger description of violin, to which the part between the second violin and bass is generally assigned. It has 4 gut strings, the two lower covered with silvered copper wire. They are tuned by fifths, thus,



, exactly an octave above the violoncello. The compass is from  to  , or higher, and the music is generally written on the alto clef.

VIO'LA D'AMO'RE, an obsolete instrument of the viol tribe, revived a few years ago with some success by M. Urhan at Paris. It had 5 or 7 strings of catgut, which were placed and played as in other bow-instruments; but below them, and passing underneath

the bridge, were 5 or 7 other strings of metal tuned in unison with them, which vibrated sympathetically when the former were played; giving to the music a mysterious resonant character. The compass was at least three octaves and a half. The strings of M. Urhan's viola d'amore were tuned in thirds and fourths, thus:



VIOLA'CEÆ, a natural order of exogenous plants, of which about 300 species are known, natives both of temperate and tropical countries, those belonging to the former being generally herbaceous, and those belonging to the latter generally shrubby. They have simple leaves with persistent stipules. The calyx consists of five persistent sepals, usually elongated at the base; the corolla of five hypogynous petals, unequal in the sub-order *violeæ*, and equal in the sub-order *alsodeæ*. There are five stamens inserted in a hypogynous disk; the filaments prolonged beyond the anthers. The ovary is one-celled, generally with many ovules, the style single, with an oblique stigma. The fruit is a three-valved capsule, with many seeds. The best known species are the violets (q.v.), noted for their beauty and fragrance. Emetic and purgative properties prevail in the order, and some of the South American species, particularly of the genus *ionidium*, yield valuable medicines. See IPECACUANHA and CUICHUNCHULLI. Yet the leaves of the lobolobo (*conohoria* or *alsodeia lobolobo*) are used in Brazil as spinach.

VIOLENT PROFITS, in the law of Scotland, mean the income or rent enjoyed by one who forcibly or unwarrantably detains land to which he has no title. Such profits are held to be the full profits which the landlord could have made either by possessing the lands himself or by letting them.

VIOLET (*Viŏla*), a genus of herbaceous plants, mostly perennial, of the natural order *violaceæ*. They have a short stem, or are stemless, having in the latter case a short root-stock (rhizome); the leaves are alternate, and have long stalks; the flowers have five petals, different in form and size, the lowest having a spur behind. Nearly 200 species have been described, natives chiefly of northern temperate countries. Several species are much cultivated in gardens, some as *V. tricolor*, on account of their beautiful flowers; others, as *V. odorata*, on account of their fragrance. *V. tricolor*, the PANSY, PANSY VIOLET, HEART'S EASE, is very abundant in fields, meadows, woods, etc., in Britain and in most parts of Europe, and the n. of Asia; it is also found in North America, although it has probably been introduced here from the old world. It is a very variable plant, its flowers differing much in size and color, but is readily distinguished by its large lyrato pinnatifid stipules. The stem is somewhat triangular, branching, and diffused. In some of its most common forms, this plant is a mere despised weed, with small flowers: other wild forms have much larger flowers; and to it are referred the large and beautiful garden pansies, the varieties of which are innumerable. The pansy (Fr. *pensée*, probably from the drooping attitude of the flower, suggestive of thoughtfulness) is one of the finest of florists' flowers, and no flower has been more improved by cultivation. Another species has of late years been introduced into cultivation, *V. altaica*, a native of Siberia, and by itself, or by hybridization with *V. tricolor*, has become the parent of many garden pansies. In a wild state, it has oval leaves, and large yellow or purple flowers. The finest garden pansies are not preserved or propagated without great difficulty, and require most careful cultivation, without which they quickly relapse to their wild forms. Florists demand that a pansy shall have a round, flat, and very smooth edge, the petals thick and velvety, the three lower petals alike in their ground color, the lines or pencilings in the center bright and distinct, the two upper petals—which always differ in color from the others—perfectly uniform, the flower measuring at least an inch and a half across.—The SWEET-SCENTED VIOLET (*V. odorata*) is common in grassy places in England, and throughout Europe and the n. of Asia. The flowers are either of a deep blue color or more rarely white. Several other species, with pale blue flowers, and destitute of smell, are common in meadows and woody glades in Britain and other parts of Europe.—The DOG VIOLET (*V. canina*) is one of the most common ornaments of hedgebanks.—North America has a number of species, one of which, *V. blanda*, is sweet-scented. The Himalayas produce a number of species very similar to those of Europe. The roots of several species of violet were formerly used in medicine. They contain a bitter alkaloid, *violine*, which acts as an emetic and purgative. The petals of the sweet-scented violet are used for the preparation of *juice or syrup of violets*, which is used as a gentle purgative for children, and also as a chemical test, being reddened by acids, and rendered green by alkalies. The bruised leaves of *V. tricolor* are sometimes used as a remedy for ringworm.—The DOG'S TOOTH VIOLET (*erythronium dens canis*) has no connection with this genus, but is a very beautiful flower of the natural order *liliaceæ*.

VIOLET STONES, the name given to certain stones found upon high mountains, as in Thuringia, upon the Harz mountains and the Riesengebirge, which, in consequence of being covered with what is called *violet moss*, emit a smell like that of violets. They retain this smell for a long time, and it is increased by moistening them.—The VIOLET MOSS (*byssus iolithus*), which some botanists have been inclined to rank with lichens, and others with fungi, consists of simple articulated threads, and spreads over the stones in

the form of a delicate incrustation, which at first is reddish brown, but in a more advanced stage, yellowish green. It was formerly in use as a popular remedy for feverish cutaneous eruptions.

VIOLIN, the most popular of stringed instruments played with the bow. Its primitive form developed out of the lyre and monochord, the strings from the former, and the principal parts, the elongated resonant-box with its sound holes, finger-board, and movable bridge from the latter. The true history of the violin begins with the invention of the bow, which was first applied to the Crwth (q.v.), some time before the 13th century, when the viole, or vielle, of the Troubadours made its appearance. The rebec, the geige, the fidel, and many kinds of viols and violas underwent various changes until towards the middle of the 16th century the true violin model appeared, and drove all other instruments of the same class away, except the viola, the violoncello, and the double bass. The primitive fiddles had no contour, and it was not until the 13th century that the body of the vielle was scooped out at the ribs, forming a kind of waist. The corner-blocks were added about the 15th century, and it is supposed they originated in Germany. The foundation on which violin-making was to rest was the viol with the double-corners. These produced a new constructive feature, the "bouts," the ribs which curve inward between the two corner-blocks. These "bouts" rendered it possible for the first time for a player to get at the strings. At first they were made of enormous size and were tapered down at a later date. For nearly a century the sound-holes were shifted all over the violin, sometimes crowding with the bridge near the tail-piece. It was not for some time after the violin model had been in that they were cut in their proper place and the bridge fixed between them. The bridge was the last point perfected, and by Stradivarius. The violin, as we have it, is about three centuries old. Violins may be divided into two classes, those made on the high and those on the flat model. The former is characteristic of the Stainer pattern, the latter of Stradivarius. The violin, viola, and violoncello are identical in construction except as regards size. The violin consists of seventy different parts, all of which, except the strings and loop, are made of wood. These are: back, two pieces, sometimes one; belly, two pieces, sometimes one; six blocks; six ribs; twelve linings; one bar; twenty-four pieces of purfling, the narrow border outlining the form of the instrument; the nut, fingerboard, neck and lower nut. The movable fittings are the tail-piece, loop, button, or tail-pin, four screws, four strings, sound post, and bridge. The wood chosen is of three kinds: maple for the back, neck, ribs, and bridge; ebony for the finger-board, nuts, screws, tail-piece, and button; and pine for the belly, bar, blocks, and linings. The purfling is made partly of ebony and partly of maple. Some makers use whalebone as the more pliable. Next to cutting the scroll, purfling is the most difficult part of violin-making. A groove is cut around the edges of the instrument for its insertion, and much art is required to bend it into shape before it is laid in its place. The outline is first traced on a plate of hard wood, from which a pattern is cut. This serves for the back and belly. The mold is next made from a block of hard wood, spaces are cut in it for the blocks, the edges trimmed, and finger-holes pierced so that the pattern may be manipulated. The back is the first part made. It is shaped and hollowed out of a block and brought to the right curves by means of four templates of different sizes, cut to curves the reverse of those intended for the surface of the instrument. The top and bottom blocks are prepared and shaped. Strips of maple are prepared for the ribs, being dipped in water and bent to the curves by a hot iron. These are glued to the blocks, which are placed one in each bout, and at the top and bottom of the instrument. The entire form is then screwed in a frame and left to dry. When this is removed the back is glued on to the ribs, and filled with linings of pine passing from block to block and dovetailed at each end. After the bass bar has been placed under the left side of the belly, this is glued to the other side of the ribs. The head and scroll are then carved, the neck, tail-piece, and small fittings adjusted, and the instrument is ready for its various coats of varnish. The most celebrated violins are those of the Cremona and the Brescian makers. The former are unrivaled. Their reputation is mainly due to the brothers Amati (q.v.), who developed the model to which Joseph Guarnerius (q.v.) and Stradivarius (q.v.) added power and tone. The latter carried the violin to its perfection in design and capacity. The Brescian makers worked from about 1580 to 1640, and include Gaspard di Salo and Maggini, whose characteristics are shared by Andreas Amati, the earliest maker of Cremona. The violin makers of South Germany form a distinct school. The most noted of them are Stainer and Klotz. The best French makers are Vuillaume (q.v.) and Lupot; the English, Furber and Hills. Violin-playing dates from about the 16th century, and the first form of composition was the violin sonata, which originated in Italy. The most eminent early composer for the violin was Corelli (1653–1713), who marks an era in violin-playing. His works were models for his successors. After him stands Tartini, the next greatest representative of the violin school. Tartini makes great advance in the use of the bow. Haydn's and Mozart's chamber music aided much in giving the violin importance. As teachers in the newly founded Conservatoire of Paris, Rode, Kreutzer, and Baillot laid down principles in violin-playing, which are maintained to-day. The style of the Paris school was taken to Germany by Viotti and Rode, who bequeathed their place to Spohr, one of the greatest influences in violin-playing. Paganini caused a revolution in technique, which affected all

schools, though he founded none. The most striking representatives of the modern French school are de Bériot (1802–1870), and Vieuxtemps (1820–1881). Habeneck, Sainton, Prume, Alard, Leónard, Massart, Sarasate, Wienawski, and Teresina Tua belong to this school. In Germany the schools of Leipsic, Cassel, and Vienna are the most important. Ferdinand David, Spohr's pupil (1810–1873), the founder of the Leipsic school, has been the greatest factor. The most eminent of his pupils is August Wilhelmj (1845), whose broad tone and wonderful technique make him second only to Joachim. Through Joseph Boehm the Vienna School attained renown. Its representatives are Joachim, Jakob Dont, Jansa, and Mme. Normann-Néruda. Ole Bull (1810–1880), the Northern Paganini, belonged to no school and left no influence in violin-playing. See Rühlmann, *Geschichte der Bogen-Instrumente* (Brunswick, 1882); George Dubourg, *The Violin* (London, 1852); Sandys and Foster, *History of the Violin* (London, 1864); Hart, *The Violin and its Music* (1881); and Vidal, *Les instruments d l'archet* (3 vols., Paris, 1876–'8).

VIOLLET-LE-DUC, Eugène Emmanuel, b. Paris, 1814; studied architecture and became proficient in designs of the Gothic style. His reputation in his profession is very high, and he was specially skilled in the restoration of churches. Perhaps his best work in this direction is the restoration of Sainte Chapelle. The changes in Notre Dame, Paris, were the joint work of M. Viollet-le-Duc and M. Lassus. He was a grand officer of the Legion of honor and an honorary member of the Royal academy, London. He produced several books on architecture, which have been translated into English, and a *Memoire sur la Defense de Paris* (1871). He d. 1879.

VIOLONCELLO (diminutive from Ital. *violone*, large viol or double-bass), a large instrument of the violin class, held by the performer between his knees. It has four gut strings, the lowest of them covered with silvered copper wire, and is tuned thus, in fifths:  . Its compass extends from  to 
Its signature is usually the bass clef, the tenor or treble clef being used for the higher notes.

VIOMÉNIL, Antoine Charles du Houx, Vicomte de, 1728–1792; b. France, entered the army in which he attained the rank of field marshal. He assisted the Polish confederation against Russia in 1770. Coming to America in 1780 as Rochambeau's second in command, he gained distinction at the siege of Yorktown, and was soon made lieut. gen. After his return to France, he became governor of La Rochelle. He died from wounds received in defending Louis XVI. in the assault upon the Tuileries.

VIOTTI, Giovanni Battista, an eminent violin-player; b. at Fontanetto in Piedmont, in 1753, and chiefly educated under Pugnani at Turin. After holding for a short time the appointment of first violinist in the royal chapel at Turin, he relinquished that office, in order to travel in Europe with Pugnani. In Berlin, St. Petersburg, Paris, and London, his playing created a *furore*. He first visited London in 1792, and was engaged there at Salomon's concerts, and for a time as leader of the orchestra in the king's theater. A groundless charge raised against him of being a revolutionary agent drove him from England; but after living for a time in retirement at Hamburg, he returned to London, entered into speculations which ruined his fortunes, and died there in 1824. His compositions include violin concerts and quartetts for violin, tenor, and violoncello, violin duets and solos, and a few piano-forte compositions. His playing was characterized by a vigor of style and purity, as well as brilliancy and elegance, previously unknown; and he has been considered the father of the modern violin school.

VIPER (*Vipera*), a name common to the members of the family *Viperidæ* (q.v. for the characters common to all the vipers). The only V. found in Britain is the Common V. or Adder (*Pelias berus*), found throughout Europe from the north of Russia to the Mediterranean, and in many parts of England and Scotland, but not in Ireland. The latter seldom attains a length of much more than two feet. The head is depressed, widening between the eyes, the gape as long as the head. Like the rest of the family, it has a pair of mobile fangs in the upper jaw. The neck is smaller than the back of the head. From the neck, the thickness increases to near the middle of the entire length, and then diminishes to the vent. The tail tapers rapidly to a point. It is one of the few vipers having head shields. It has two diverging marks between and rather behind the eyes, a spot on each side of the hinder part of the head, a row of confluent rhomboidal spots running zigzag along the upper surface, the whole length of the body and tail, and a row of small, irregular, almost black, triangular spots on each side. The under parts are of a lead color. The characteristic markings are almost invariable; but the ground color varies considerably, from nearly olive, rich deep brown, or brownish yellow, to almost black. Thus, in some parts of England, a Black V. is occassionally met with; its ground color a rich black, and the markings of a more intense black than the rest. There is also the "red" or the "blue bellied," or an almost white viper, with black markings; diversities which have led some naturalists too hastily to describe the snakes

to which they belong as distinct species, but *Pelias berus* is the only venomous serpent found in Britain. See illus. Reptiles, vol. XII.

The name V.(Lat. *Vipera*) is manifestly a contraction of *Vivipera* for *Vivipara*. The name Adder arose from writing *an adder*, for *a nadder*. The A. S. is nædre, Old Eng. *naddere, neddere*, or *addere;* Scot. *nether*. It is unconnected with *attor*, poison. Pliny, Galen, and other ancient writers ascribe great medicinal value to broth made of vipers, and to the flesh of the animal. Vipers entwined together, in hybernation were supposed to produce the *Ovum Anguinum*, to which virtues were attributed; and *snakestones* as charms were at one time common in Britain. They were either marbles, or glass beads of various forms, supposed to cure vipers' bites, and to be otherwise useful.

VIPERIDÆ, a family of snakes, that, with a second family, *Crotalidæ*, (q.v.), constitutes *Viperina*, the third sub-order of *Ophidia*. The general viperine characteristics are the wide angular, depressed head, causing the neck to appear small in comparison; a short thick body; and a tail tapering suddenly to a point. In some of the largest vipers the short, unmistakeable tail is only two inches in length. The head is mostly covered with scales, rarely plates, or only a few about the eyes and lips, or with extremely fine plates. The scales are carinated, often rough, even spinous. The ventral shields are broad, and the sub-caudal plates in two rows. The nostrils are large and in some species they close with a valve. This highly venomous family of serpents are furnished with a pair of long, curved fangs. In this order, the upper maxillary, bearing two isolated fangs fixed to it, is reduced to a mere wedge of bone, which is movably articulated, and by especial muscles rotates or rocks to and fro, and the fang with it. The action is volitional as a whole. The viperine snakes are often said to have "movable fangs," though the fangs themselves do not move independently, but only with the bone to which they are attached. Thus, when at rest, the fang, protected by a membranous sheath, lies supine along the jaw; but when in use springs down by the rotation of the maxillary bone, just as a scythe might point downwards or horizontally by the movement of the handle. The fang has a canal in its interior, connected with a poison gland, the contents of which are ejected into the wound made by the fang in the act of biting. Behind the pair of functional fangs, others, in a rudimentary stage, are found, and may even create a wound, though, being as yet unconnected with the poison duct, they do not convey venom into the wound. The lower jaw has numerous solid teeth of the ordinary form. Formerly, the vipers were confounded with colubrine snakes; and even at the present day the authorities differ in the arrangement of *genera* and *species*, on account of the forms running so much into each other. Dumeril gives six genera and seventeen species; Wallace, three genera and twenty-two species; and Gray, nine genera and twenty species. Those of the family best known are the "River Jack" of West Africa, the Horned Viper or Cerastes (q.v.) of Northern Africa and the west coast of Asia, the Carpet Snake of India. The V., as above mentioned, are for the most part distinguished by their broad, flat, angular head; thick, heavy body; short, tapering tail; rough carinated scales; and a generally hideous physiognomy which seems to express their noxious qualities. Nevertheless, some of them possesss a handsome exterior, and are adorned with dark rich colorings and patterns. The *Daboia* of India is one of these, and being of a less clumsy form, has been named *Vipera elegans*. The true vipers, or those which have not the nasal fosse, are most largely represented in Africa, which has about twelve species. Europe has three; India two; and South America only one very small but intensely poisonous species, the Peruvian adder (*Echidna ocellata*), not much known. The anomalous Death Adder (*Acanthophis antarctica*) of North Australia, with its unmistakably venomous look, is included among the vipers; notwithstanding it has a pair of *fixed* fangs like the *Elapidæ*. The largest and deadliest species are found in tropical countries. They inhabit dry sandy deserts, and are of a retiring, sluggish nature. See Lachesis, Asp, Puff Adder, Rattle Snake, etc.

VIPER'S BU'GLOSS, *Echium*, a genus of plants of the natural order *boragineæ*, having a calyx with five deep segments, an almost bell-shaped corolla, with dilated throat, and irregular limb, very long unequal filaments, and a bifid style. The species are large herbaceous plants or shrubs, rough with tubercles and hairs. Their flowers are often very beautiful. The Common Viper Bugloss (*E. vulgare*), a large annual plant, is a native of Britain and of most parts of Europe, growing in dry places, not unfrequently in corn-fields. Its flowers are at first reddish, and afterward blue. It derives its name, viper bugloss, from spots on its stem, which somewhat resemble those of the viper; and the property of healing vipers' bites was, therefore, ascribed to it. Other herbaceous species are found in the s. of Europe, North and South America, and other parts of the world. Shrubby species are found chiefly in the Canary islands and in s. Africa.

VIRCHOW, Rudolf, pathologist and publicist, was b. at Schivelbein, Prussia, Oct. 13, 1821. He was a pupil of the great physiologist, Johann Müller; graduated in medicine in 1843; and became, in 1847, lecturer at the university of Berlin. Soon afterward he was commissioned by the government to investigate the cause and cure of typhus in Silesia; and also, in conjunction with Reinhardt, founded the annals of pathological anatomy and of clinical medicine. The political commotions of 1848 dragged him, in common with many other votaries of science, into the revolutionary vortex. He established a journal entitled the *Medical Reformer*, and also a democratic club, where he soon dis-

tinguished himself as an orator. He was, in consequence, elected a member of the national assembly, but was not admitted because he was, in a parliamentary sense, a minor. With the conservative reaction, Virchow had his journal suppressed, and lost his post, but was elected to the chair of pathological anatomy in Würzburg. His lectures at that university were widely popular for the novel views which he struck out particularly in cellular pathology. His reputation grew so great that he was recalled by Manteuffel in 1856 to Berlin, where he re-occupied the chair of pathological anatomy, and rendered it the most famous of its kind in Europe. In 1859, when the liberal cause revived, he became a member of the municipal council of Berlin, where he distinguished himself as a reformer of the arbitrary police system then rampant; and soon after was chosen deputy by the electoral college of Saarbrück, and by two of the Berlin colleges. He soon rose to the leadership of the opposition, and proved a most effective antagonist of the encroachments made in the name of the royal prerogative. He took the lead, in Jan., 1863, in carrying the address in which the ministry were accused of having violated the constitution. Such was the energy of his opposition, that in June, 1865, he was challenged to a duel by count Bismarck. In 1878 he retired from parliamentary life, in order to devote himself exclusively to science, after having been for years a prominent member of the advanced liberals in the Reichstag. Among his works are his inaugural thesis, *De Rheumate Corneæ* (1843); *The Colloid Tumours of the Ovaries, and on Cancer* (1847); *Cholera* (1848–49); *Flexions of the Uterus, Scrofula, Tuberculosis, Typhoid Fever* (1850); *Cellular Pathology* (1850); *Amyloid Degeneration* (1853); *Morbus Spedalska* (a disease peculiar to the Norwegian coasts, 1859); *Trichiniasis* (1860); *Tumours* (1862); *Cellular Pathology in its foundation on Physiological and Pathological Histology* (1871); a notable article *On the Standpoints of Scientific Medicine* (1878). During the wars of 1866 and 1870–71, Virchow took an active interest in the sanitary arrangements for the troops in the field. In 1892 he was elected rector of the university of Berlin; in 1894, received the grand cross of the order of Sts. Maurice and Lazarus from the king of Italy; and in 1896 was appointed a commander of the legion of honor by the French government.

VIRE, a t. of Normandy, France, in the department of Calvados, picturesquely situated on a hill washed by the Vire, 35 m. s.w. of Caen. It is an important center for wooden manufactures and carries on a trade in granite quarried in the neighborhood.—*Vaux de Vire* (see VAUDEVILLE). Pop. '91, 6363.

VIREO, or GREENLET, the common name of a family of insectivorous birds, having a plumage more or less tinted with green and olive. In the genus vireo the bill is short and strong, nearly straight, notched and hooked at the tip. The wings are long and pointed; toes of moderate length; tail moderate and even. There are about 20 species, migrating from South America and the West Indies to the United States, arriving there in May, breeding during the summer, generally having two broods in a season, and returning in the autumn. Many of these beautiful birds are very sweet singers, and destroy a great many insects. The nest is made in trees and bushes of dried leaves, moss, grass, etc. The red-eyed vireo, *V. olivaceus,* is about 6 in. long, and a little over 10 in alar breadth. The tail is a bright olive-green above; top of the crown ashy, and white below. The iris is red. Its range is from eastern United States to Missouri, and from Greenland to Central America. A more southern species is *V. barbatulus,* or Whip-Tom-Kelly. The solitary vireo, *V. solitarius* of Baird, about 5½ in. long, and 9½ in alar extent, is found in the United States from the Atlantic to the Pacific. Upper parts dark olive-green; white rings around the eyes, two bands on the wings, and edge of secondary feathers white; greenish-yellow under the wings.

VIRGIL, the Magician, is the character in which the great Roman poet presented himself to the popular imagination of the Middle Ages. The origin of this singular delusion may be thus explained. From a very early period—almost, we may say, from the age in which he flourished—Virgil was acknowledged to be the prince of Latin poets. His poems threw all others into the shade, and this, not so much because they exhibited a finer and more original genius, as because their style was perfect, the subject of his *magnum opus* thoroughly national, and his immense historical and antiquarian lore devoted to the glorification of the Roman people. From him the grammarians selected the examples of their rules, and even composed treatises on special questions suggested by his poems. The rhetoricians, too, found there material for their themes and declamations, and the later poets imitated his phraseology. Very soon the idea sprung up that in his verses there lay hidden quite a peculiar wisdom and mystic meaning. Thus it happened that, as early as the 3d and 4th c., even Christian authors (e.g., Minutius Felix, Lactantius, and Augustine) had contracted the habit of regarding him reverentially, a feeling which, in its turn, induced them to use him for polemical, or at least theological purposes. Hence they sought to prove the beginning of the fourth eclogue a Messianic prediction, and would have it that Virgil foresaw the day of Christ. This view rooted itself so deeply, that Virgil and the Sibyl (q.v.) were actually introduced into the liturgy of the church, along with the Messianic prophecies of the Old Testament, and in the "mysteries" of the Middle Ages, are frequently cited as bearing witness to a coming Messiah. Furthermore, when the first ages of polemical theology arrived, biblical critics and controversialists did not hesitate to quote the verses of Virgil in elucidation of passages of Scripture, and in confirmation of their views. Later still, some of the scholastics endeavored to give a "moral" significance to the whole *Æneid;*

and an epitome of sacred history even was manufactured out of its contents (see CENTO). Another use, or rather *mis-use* of the verse of Virgil had already begun during the Roman empire, and affords additional evidence of the superstitious reverence that was gradually encircling the name of the poet: we allude to the custom of trying to discover one's fortune by selecting lines at random from his epic. See SORTES BIBLICÆ, SORTES VIRGILIANÆ. Ultimately, as may be seen from the *Divina Commedia* of Dante, Virgil came to be considered as a representative of pure enlightened reason; a highly-gifted genius standing midway between paganism and Christianity.

We have remarked that this deep, half-religious veneration for Virgil displayed itself at a very early period. Soon after his death, statues were erected to his memory, even in the domestic chapels of the emperors; the anniversary of his birth was held sacred; pregnant women and poets made pilgrimages to his tomb, and hence it became inevitable that all sorts of myths should spring up and attach themselves to his history; but the predominant conception in the middle ages was that of a wise, pure, and patriotic teacher, endowed with magic power and lore—quite a different kind of being from the evilly disposed and dreaded "sorcerer" of popular fancy. The Virgilian myths established themselves more especially in connection with the places where he was born, where he chiefly lived, and where he died—Mantua, Rome, and Naples; and there they even yet survive, in some measure, on the lips of the people. But, curiously enough, it was not from the Italians, but foreigners, that they first obtained literary consideration. The oldest document bearing on the subject, of which we have any knowledge, is the *Otia Imperialia* of the Englishman, Gervase of Tilbury, who collected his stories from the mouths of the Neapolitan populace. A fuller account is to be found in the *Chronicle* of Arnold of Lübeck, who got his information from Conrad, bishop of Hildesheim, chancellor of the emperor Henry VI. These were followed by their contemporaries, Helinandus, whose legendary history of Virgil is embodied in the 6th book of Vincentius Bellovacensis' *Speculum Historiale*, and the English monk, Alexander Neckam, in his *De Naturis Rerum*, the best parts of which (relating to Virgil) are preserved in the repeatedly published *Vitæ Philosophorum* of Gualterus Burlæus. From these four main sources the later Virgilian myth-mongers have chiefly borrowed; of whom the two chiefly deserving notice are Buonamente Aliprando (author of a chronicle of Mantua in *terza rima*, about the beginning of the 15th c.), and the so-called Pseudo-Villani (author of *Le Croniche dell' inclita città di Napoli* (Naples, 1526). Particular stories and allusions are found pretty thickly scattered through the whole literature of the middle ages after the 13th century. The first complete collection, however, of the Virgilian myths was the French "people's book," entitled *Faictz Marueilleux de Virgille*, published in the beginning of the 16th c., by Jehan Trepperel at Paris, translations of which soon after appeared in Dutch and English. Even the distant Icelanders had heard of the great magician, and there still exists in MS. an Icelandic *Virgilius-Saga*. The greater part of the Virgilian myths collected in the "people's books" are of various ages and origin, and have come down to us in different forms. Some have decidedly been shaped after eastern models, but the majority are of Latin and Italian growth.—See Zappert. *Virgil's Fortleben im Mittelalter* (Vienna, 1851); Siebenhaar, *De Fabulis* (Berl. 1837); Edélestand du Méril, in his *Mélanges Archéologiques et Littéraires* (1850). Milberg, *Memorabilia Vergiliana* (1867); Comparetti, *Virgilio nel Medio Ævo* (1872); and Tunison, *Virgil in the Middle Age* (1889).

VIRGIL'IA, a genus of leguminous trees, natives of s. Africa. Michaux referred to this, one of the finest North American trees, the yellow-wood, and called it *virgilia lutea*, but from differences in the pods and other parts, Rafinesque made a new genus for it, and called it *cladrastis tinctoria*, which is its present botanical name. The name of virgilia is, however, commonly applied to it. It grows to a height of 30 or 40 ft. and a diameter of about one foot. It has long compound leaves, with from seven to eleven leaflets, the base of the petiole being expanded to cover the bud of the following year. The flowers are in loose, pendent racemes from 10 to 20 in. long, of a pure white, except a small yellow spot in the center of each. They have the appearance of *papilonaceæ*, but their distinct stamens and other characteristics place them among the *sphoreæ*. The pod is from 3 to 4 in. long, narrow, flat, and four to six seeded. The tree is hardy in the latitude of Boston, and it is easily raised from the seeds. It is a fine garden tree.

VIRGIL'IUS (or, as it is more accurately spelled, VERGILIUS) **MA'RO**, PUBLIUS, after Homer, the greatest epic poet of antiquity, was born in the consulship of Crassus and Pompey, Oct. 15, 70, B.C., at Andes, a village not far from Mantua. It is probable that his father was the proprietor of a small estate which was farmed by himself. Virgilius was liberally educated, and is believed to have studied successively at Cremona and Mediolanum (Milan). In philosophy, he was instructed by Syron, an Epicurean, and one of his fellow-students was that Varus to whom his sixth eclogue is dedicated. Greek he learned at Neapolis (Naples) from the grammarian Parthenius. If we are correct in supposing that, in the first eclogue Virgilius relates his own experience in the person of Tityrus, he first visited Rome 41 B.C., in his 30th year, for the purpose of reclaiming his lands, which were occupied by the soldiery of Octavianus, at the close of the war against the republicans. At Rome, he was introduced to Octavianus, through the influence of Pollio, or of some other patron, and further formed the acquaintance of his great pro-

tector, Mæcenas. He continued to compose his eclogues—the tenth and last of which is dedicated to Gallus, and referred to the poet's 33d or 34th year. At the instance of Mæcenas, he commenced his *Georgics* in his 34th year, according to the grammarians, who also assign 7 years as the time he spent in the composition of the work, which was carried on principally at Naples. The *Æneid* was his last performance, and must have occupied many of the latter years of his life. He went in 19 B. C. to Greece, where he meant to subject his great poem to a thorough process of revision and refinement; and his voyage to Athens was made by Horace the occasion of the ode (book i. 3) commencing with "Sic te diva potens Cypri." At Athens, Virgilius met Augustus on his triumphal return from the east, and the poet was induced to go back to Rome in his company. He had only got as far as Megara, however, when he was seized with illness, which became worse on his voyage to Italy. On landing at Brundisium, or, according to another account, at Tarentum, he was unequal to the fatigue of traveling; and after lingering for a few days, he died, in the 52d year of his age, 19 B. C. In compliance with his dying wish, his body was removed to Naples, and buried at the second mile-stone from that city, on the Puteolan Way. Pliny the Elder and Aulus Gellius are among the writers who say that on his deathbed Virgilius desired his epic poem to be burned, rather than that it should see the light in its imperfect state; but that the injunctions of Augustus to his executors, or, according to others, the interposition of his friends Tucca and Varius, who persuaded him to bequeath it to them on the understanding that it should remain unaltered, were the means of preserving it. This incident is quite in keeping with all that we know of Virgilius's modesty of character. The liberality of his patrons had endowed him with considerable property. He had a house on the Esquiline, near the gardens of Mæcenas, where he lived with an elegant simplicity, while he allowed the public free access to his excellent library. He was tall of stature, dark of complexion, and had the appearance of a farmer. His most finished poem is the *Georgics*, in which the various departments of agricultural concern are described with great clearness, and illustrated by episodes of the finest poetry. His *Æneid* shows rather what he might have been than what he was as an epic poet. Unfinished as it is, however, its merits have always secured him a place in the front rank of epic writers; while, more than any similar work of antiquity, it has furnished a model to the epic and narrative poets of modern Italy. He has been edited and translated by scholars of nearly every country and period. The best English translation is that of the *Æneid* by William Morris (1875), which is on the whole superior to Dryden's, before unequaled. Conington's *Æneid* is in some features highly successful. The best editions are those of Heyne, Wagner, Forbiger, Ribbeck, and Conington. See the fine study of Virgil by Nettleship in his *Lectures and Essays* (1888); and by Sellar in his *Roman Poets of the Augustan Age* (1880).

VIRGINALS, a keyed instrument of former times. As described by Dr. Burney, it resembled in form a small pianoforte, with a compass of four octaves, furnished with a quill and jack like those of the spinet, and a single string to each note. Queen Elizabeth is said to have been a skillful performer on the virginals; but the instrument cannot, as popularly supposed, have been named in honor of the virgin queen, having been so called before her majesty's time.

VIRGINIA, a southern Atlantic state and one of the original 13, between lat. 36° 31′ and 39° 27′ n.; long. 75° 13′ and 83° 37′ w.; bounded on the n. by West Virginia and Maryland; on the e. by Maryland and the Atlantic ocean; on the s. by North Carolina and Tennessee; on the w. by Kentucky and West Virginia; greatest length from e. to w. about 475 m.; greatest width about 200 m.; gross area, 42,450 sq. m., or 27,168,000 acres; land surface, 40,125 sq. miles.

HISTORY.—V., popularly called the Old Dominion, whose shores were first explored by Sebastian Cabot, 1498, and again under the auspices of sir Walter Raleigh in the reign of queen Elizabeth, in whose honor it was named, was first settled by an English colony, under the charter of the London company, at Jamestown, on the James river, May 13, 1607—a colony consisting of gentlemen of fortune and persons of no occupation, no families, 12 laborers, and very few mechanics. The friendly Indians of the Powhatan tribe sold them land and provisions; but the diseases of a damp climate swept off half the settlers the first summer. The energy of Captain John Smith saved the colony from destruction, and in 1609 it was re-enforced with 500 persons, including 20 women and children, who were reduced by sickness and starvation to 60. They had embarked, to abandon the settlement, when lord Delaware came with emigrants and supplies. In 1610 a church was erected at Jamestown—the first permanent religious edifice erected by Englishmen in North America. The marriage of John Rolfe to Pocahontas (q. v.) in 1613 secured the friendship of the Indians. In 1619, 90 respectable young women were sent out from England, and each planter, on giving 120 lbs. of tobacco to repay the cost of her outfit and passage, was entitled to a wife. In addition 100 convicts were sent to supply labor, and a Dutch trader also sold the colonists 20 negroes. In 1619 Puritan emigrants arrived and continued to come, until it was estimated that nearly 1000 persons were of "similar mind;" but in 1643 laws were passed compelling conformity to the English church, and the Independents, as they styled themselves, were fined or imprisoned, and finally emigrated to Maryland and New England. In 1643 a public school was opened. Silk culture was undertaken; trade became brisk with England, Holland, and New England, and in 1649 the colony was increased by the arrival

of 300 royalist fugitives. In 1650 the Long Parliament prohibited trade with V., and in 1652 sent a fleet to receive the surrender of "the traitorous province;" but the burgesses yielded only on condition that their act should be acknowledged as voluntary, and in return received indemnity for acts and words against the parliament, were allowed free trade with all nations, also the sole right to tax V. In 1660 the house of burgesses declared that the supreme power of the government was to be resident in it, and that all writs should issue in its name. In 1622 the colony was reduced by wars and massacres from 4000 to 2500; but in 1624 it became a crown colony, and increased.

In 1671 the population was 40,000, including 2000 black slaves. The now prosperous colony consisted of 48 parishes, but had, Governor Sir William Berkeley thanked God, no free schools or printing, which he hoped they might keep free of for a hundred years, saying, "God keep us from both!" In 1754 the colonial militia took part in the French war, and Maj. George Washington was in Gen. Braddock's expedition. In 1764 the house of burgesses remonstrated against the attempt of parliament to tax the colonies without their consent, and in 1765 Patrick Henry introduced resolutions of similar import, which were adopted. In 1773 Patrick Henry, Thomas Jefferson, and Richard Henry Lee were appointed a committee to confer with the other colonies, and urged upon their delegates the declaration of independence. In 1774 the burgesses protested against the closing of the port of Boston, and called for a general congress of the colonies to inaugurate resistance, and in 1775 the colony began raising companies of volunteers. Lord Dunmore proclaimed martial law, and on Nov. 23 occupied Norfolk with a British and Tory force, but soon retired, and on Dec. 9 was defeated at Great Bridge by the V. volunteers. Returning in Jan., 1776, by sea, he bombarded Norfolk, and continued to ravage the coast, but was finally forced to retreat. In 1776, May 15, a convention of the colony instructed its delegates in congress to propose to that body to "declare the united colonies free and independent states." This declaration was written by Thomas Jefferson, a Virginian. A declaration of rights was adopted on June 15, and on June 12 a new constitution. In 1779 the British destroyed Norfolk and the shipping on the James and Elizabeth rivers, and took Portsmouth and Gosport, and in 1781 Richmond was burned by Benedict Arnold, and eastern V. was invaded by Cornwallis and Phillips. The revolutionary struggle ended on V. soil with the surrender of Cornwallis at Yorktown, Oct. 19. The federal constitution was ratified by V. June 25, 1788. During the first half of the present c. V. maintained her prominence in national affairs, and having been the birthplace of 7 of the presidents of the U. S., received the honorable title of "the mother of presidents."

In 1859 an attempt was made at Harper's Ferry by John Brown and other abolitionists to free the slaves. When the secession of the southern states from the union began to be considered, the people of V. were divided in their desires. Many of them were strongly attached to the union and objected to a separation. Jan. 7, 1861, the legislature met in extra session, and subsequently provided for the assembling of a convention to determine what course should be adopted by the state, and passed resolutions recommending the states to appoint commissioners to a national peace convention to be held in Washington. Nothing beneficial resulted from this proceeding, however.

On Feb. 13 a convention met at Richmond, and on Mar. 10 resolutions were introduced declaring secession to be a right and protesting against interference with slavery. During the first week in April the convention refused to secede by a vote of 89 to 45, but the proclamation of Pres. Lincoln, calling for troops, led to the passing, Apr. 17, of an ordinance of secession by a vote of 88 to 55, which was soon ratified by the people, the counties now constituting West V. refusing to be bound by this action.

The state authorities took possession of the custom-house in Richmond, the navy-yard at Norfolk, the U. S. arsenal at Harper's Ferry, and other property; troops were called out, and money was raised for arming and equipping them. May 7 the state was admitted to representation in the confederate congress, and later in the month Richmond was made the seat of the confederate government. From this time, during the whole of the war that followed, V. was occupied by hostile armies and was the region of almost continual military operations, by which it suffered much. There were fought within the state the great battles of Bull Run, Carnifex Ferry, Ball's Bluff, Williamsburg, Winchester, Hanover Court-House, Seven Pines, Fair Oaks, Cedar Mountain, Manassas, Fredericksburg, Chancellorsville, Hanover Junction, the series of battles from the Wilderness to Cold Harbor, in May and June, 1864, Petersburg, Cedar Creek, Fisher's Hill, the battles in the valley, Lynchburg, and Five Forks. During most of the time there were 2 state governments in V., the w. cos. having maintained allegiance to the union and instituted a separate government under federal control. After the surrender at Appomattox Court-House this government was recognized by the president as the lawful one, and for a while the whole state became subject to it. In 1867 V. was made the first military district, under Gen. Schofield. In that year delegates to a constitutional convention were chosen by the voters who had taken an oath of allegiance to the federal government, the majority of the whites opposing the movement. The convention assembled at Richmond in Dec., but the new constitution was not ratified by the people until July, 1869, and the state was not readmitted to representation in congress until Jan. 26, 1870.

Topography.—V. has six great natural divisions extending from n.e. to s.w., and corresponding to the trend of the Atlantic coast on the e. and of the Appalachian range

on the northwest. They differ in geology, climate, soil, and productions. Beginning on the e., they are the tide-water, middle, Piedmont, Blue Ridge, Valley, and Appalachian sections. The tide-water portion is divided by Chesapeake Bay and the large tidal rivers which flow into it into 9 primary and many subordinate peninsulas, no part of which is elevated more than 100 ft. above the sea, and considerable tracts are low and marshy. Middle V., a triangular tract extending from a n. and s. line running through Richmond to the foot-hills of Southwest Mountain, is a wide, undulating plain of no great elevation (perhaps an average height of 400 ft.), through which the many rivers that traverse it have cut their channels to a considerable depth, and are bordered by alluvial bottom-lands. Along the e. base of the Blue Ridge Mountains, and between them and the coast range, the Piedmont division extends from the Potomac and Maryland to the Dan at the North Carolina border. It is 244 m. long, with an average width of 25 m. and an area of about 6000 sq.m. The Blue Ridge division is a still narrower belt. It includes both slopes of the Blue Ridge, and forms the eastern wall of the valley of V., the 5th division, which is a part of the great Appalachian Valley, lying between the Blue Ridge on the e. and the Endless Mountains on the west. The Valley is a broad belt of rolling country from 1200 to 1600 ft. above the sea, diversified by hills and valleys, with several streams. The Appalachian division is a mountainous region traversed by the Alleghany ranges. In V. it is about 260 m. long and from 10 to 50 wide, and comprises 7680 sq. miles. The highest peak in the state, Balsam Mountain (about 5700 ft.), is in the Iron Mts., between the Blue Ridge and the Alleghany range, on the border of North Carolina. The peaks of Otter, in the Blue Ridge, are 3993 ft. high. What is known as the eastern shore is a narrow peninsula extending from the Maryland border to Cape Charles and comprising the counties of Accomack and Northampton.

Nearly all the streams of the state have a s. easterly course. The Potomac, Rappahannock, and James, besides many smaller creeks and rivers, empty into Chesapeake Bay. The Chowan, a river of North Carolina, receives from s. eastern V. the Blackwater and other branches, and the Roanoke, which, like the Chowan, discharges into Albemarle sound, is formed by the Dan and Staunton in the s. part of V. The Great Kanawha, or New River, a tributary of the Ohio, rises in North Carolina and crosses the s. western part of V. The main part of the James is 450 m. long, and tide-water ascends it to Richmond 150 m. from its mouth. The Rappahannock is about 125 m. long, and is navigable from Fredericksburg, where it meets tide-water. The Shenandoah, the largest tributary to the Potomac, rises in 2 branches, w. of the Blue Ridge, and has a course of 170 m., about 100 m. of which are navigable for small boats. The west shore of Chesapeake bay is cleft by numerous bays and arms of the sea, including the great estuaries of the Rappahannock and James and that known as York river, into which the Mattapony and Pamunky discharge. The Atlantic coast of the eastern shore is bordered by a series of sandbars, or islands, pierced by inlets and enclosing Broadwater and other sounds. Warm and mineral springs, some of them of wide repute, abound in the mountain and upland districts. Aside from the numerous localities of historical interest, the state is rich in scenery and in natural curiosities, among which are the natural bridge in Rockbridge co.; Weyer's and Madison's caves in Augusta co., remarkable for their stalactites; and Blowing Cave, near Millboro.

Geology and Mineralogy.—The e. coast is composed of tertiary sands, clays, and marls; further inland, strata of the miocene groups emerge from beneath these, and abut against granite, gneiss, and other metamorphic rocks, at the line of the lowest falls of the principal rivers, the head of navigation, and sites of the chief towns. The mineral resources are as yet mostly undeveloped. In the metamorphic belt are gold mines, copper, iron, etc. There are two upper secondary belts parallel to the Blue Ridge, crossing the James above Richmond, with rich coal deposits. The valley is of the lower Silurian, with rich limestones, hematite iron, and a fertile soil. On the w. borders are found sulphur, salt, obtained from artesian wells, gypsum, lead, etc. The western coal region, cut through by large rivers, is one of the finest in the world. There are also deposits of fine marble, porcelain clay, fire-brick clay, fine granite, soap stone, slate, glass-sand, plumbago, zinc, manganese, waterlime, freestone, greenstone, etc.

Fauna and Flora.—Bears, catamounts, wolves, wild cats, and deer are still found in remote or mt. regions. The beaver, otter, opossum, marten, muskrat, gray fox, red fox, ground hog, rabbit, hare, weasel, red squirrel, gray squirrel, flying squirrel, cotton-rat, etc., are more common. Among wildfowl and birds are the swan, wild goose, gull, heron, fish-crow, teal, many species of duck, the grouse, quail, wild turkey, eagle, turkey-buzzard, lark, robin, dove, oriole, tanager, mocking-bird, bobolink, etc. Rattlesnakes, blacksnakes, moccasin, copperhead snakes, and turtles and terrapins are among the reptiles. In the inland waters are found trout, bass, eels, perch, mullet, pickerel, hog-fish, etc., and the tidal waters furnish abundance of sturgeon, shad, herring, cod, bass, trout, mackerel, perch, and other fish, besides lobsters, crabs, clams, and oysters.

In the tide-water section are extensive forests of pine (the noted yellow), oak, cypress, cedar, and locust, from which large quantities of timber and sawed lumber are obtained. The middle region contains large areas of superior hard pine, black, white, and other oaks, holly, and other trees; the Piedmont has considerable forest land, with oak of many varieties, hickory, tulip-poplar, black walnut, locust, cedar, chestnut, and pine;

the Blue Ridge is mostly covered with forests of oak, hickory, chestnut, locust, and birch; the valley has much superior hard-wood timber, especially oaks and hickories; and in some parts of the Appalachian country are extensive forests that include oak, walnut, tulip-poplar, locust, sycamore, and pine. Plums, persimmons, cherries, crab-apples, grapes, cranberries, blackberries, strawberries, and other fruits and berries grow wild in great abundance. The flora of the state is exceedingly rich.

Climate and Soil.—The climate varies much in different districts. The mean annual temperature for the state ranges from 60° and 64° in the s.e., to 48° and 52° in the valley and Appalachian region, while the annual range, from the severest cold of winter to the greatest heat of summer, is not more than 86°. In the e. and s.e. the summers are hot, and in the vicinity of swampy lands bilious and typhoid fevers prevail. The region lying on and near Hampton Roads is, however, healthful and agreeable at all seasons of the year; and the valley has a healthful climate, the summer heat being tempered by the elevation and the cool breezes, while it is also sheltered by the mts. in winter.

At White Sulphur Springs the average annual rainfall is 37.54 ins.; at Fort Monroe, it is 47.04 ins. The soil of the tide-water division is a light sandy loam, capable of yielding large crops of fruit and vegetables; but it has been to a great extent worn out by superficial cultivation. In middle Virginia much of the land is fertile, and much is poor and sterile. The soils of the Piedmont region, consisting largely of decomposed greenstone, are very fertile, as are also portions of the Blue Ridge country; but where the sandstones prevail on the western slope they are sandy and poor. The valley soil is underlaid with disintegrating limestones, shales, slates, and clays, and is very fertile, and many of the valleys in the Appalachian region are rich and productive.

Agriculture.—The short mild winters and the long summers, with plentiful rains, are conducive to farming. The valley of Virginia produces immense crops of cereals, its corn averaging 38,000,000, its wheat 6,000,000, its oats 8,000,000 bushels annually. The eastern portion of the state is devoted largely to early fruit and vegetables for the northern markets; Piedmont and Albemarle have extensive orchards, vineyards, and peach groves. In the southeast, peanuts are raised in great quantities, averaging frequently forty bushels to the acre, valued at over $2,500,000 annually. The consumption has increased in this country from 2,000,000 bushels in 1885 to 5,000,000 bushels in 1894. Norfolk and Petersburg are the principal markets. A fine table oil is made from them, while locally they are made into a coarse flour. Virginia stands second only to Kentucky in the amount of tobacco produced, and its crop is nearly 70,000,000 lbs. annually. The finest comes from the Middle and Piedmont districts, and coarser grades from the mountain districts. Stock-raising and dairy farming are important industries in some portions of the central and the western counties.

Industries.—The manufacturing interests of the state have been developed slowly, though its abundance of raw material, ample water-power, and convenience of transportation give it marked advantages. The U. S. census of 1890 reported for Virginia, 5915 manufacturing establishments, employing $63,456,799 capital, and 59,591 persons, paying $19,644,850 for wages, and $50,148,285 for materials, and having a combined output valued at $88,363,824. The principal manufactures in the order of value of output are chewing and smoking tobacco, and snuff, flour and grist, saw and planing mill products, iron and steel, fertilizers, cotton goods, brick and tile, boots and shoes, tanned leather, agricultural implements, ships, and woolen goods. Valuable deposits of iron ores, particularly brown hematite, are found in the mountain sections, and over 350,000 tons of pig iron are produced annually, besides large quantities of rolled iron. The gold mines are also of considerable importance, over $1,700,000 having been deposited in the United States mints previous to 1891. This state also produces over 1,000,000 tons of coal annually, mostly bituminous. That mined at Pocahontas is used both for steam purposes and for coking. The largest lead mines in the south are in Virginia, as are also the most productive manganese mines in the country, this state having yielded more than any other. Chesapeake Bay has valuable oyster-beds, the finest on the Atlantic coast, and in 1890 the oyster, clam, terrapin, and other fisheries had an output valued at nearly $5,000,000.

Commerce.—In the fiscal year ending June 30, 1897, the imports of merchandise at the ports of Alexandria, Newport News, Norfolk and Portsmouth, Petersburg, and Richmond aggregated in value $1,392,795; and the exports of domestic merchandise, $40,691,107, the largest entries being at Newport News and Norfolk and Portsmouth, where the total foreign trade amounted to $23,278,890 and $18,703,390 respectively. The leading exports are tobacco, naval stores, cotton, lumber, and garden vegetables. The state has also developed a large general coasting trade, and in this and the foreign trade Newport News has become one of the most important ports on the Atlantic coast of the United States.

Transportation.—The principal railway systems are the Atlantic Coast Line, which is a combination of routes on various connecting lines, by which travel is possible the entire length of the Atlantic coast without change of cars; the Norfolk and Western and its divisions; the Southern, and the Chesapeake and Ohio. The whole number of miles operated in the state exceeds 7000. Other facilities are the James River and Kanawha canal, from Richmond to Buchanan, 198 miles; the Albemarle and Chesa-

peake canal, from Norfolk to Albemarle Sound; and the Dismal Swamp canal, which makes the same connections by another route.

Banks.—On Oct. 31, 1896, there were 37 national banks in operation, with combined capital $4,846,300, deposits $14,000,000, reserve $3,839,337, and outstanding circulation $2,146,099, and 86 state banks, with capital $6,241,365, deposits $14,606,504, resources $24,561,186, and surplus $2,538,487. The exchanges of the year at the clearing-house at Richmond, aggregated $115,412,712.

Religious Denominations, Education, etc.—The leading denominations numerically are the Baptist colored, Methodist Episcopal South, Regular Baptist South, African Methodist, Presbyterian South, Protestant Episcopal, Methodist Episcopal, Disciples, Roman Catholic, and Lutheran. The present public school system of the state, which is similar to that of most of the states, dates its organization from 1870. The general supervision is vested in a superintendent of public instruction, elected every 4 years by joint ballot of the general assembly, and the board of education consists of the governor, attorney-general, and the superintendent. The schools are supported by state and local taxation and a permanent state fund. Substantial aid is received also from the Peabody educational fund. Under existing laws, boards of district school trustees, with the advice and counsel of the superintendents of schools, determine where and how many schools shall be opened in each magisterial district. Reports for 1896 showed, public school enrollment, 361,559; public schools in operation, 8400 (6124 for white pupils and 2276 for colored); value of public school property, $3,000,000; annual expenditure, $1,825,000. There are public normal schools at Petersburg, Farmville, and Rye Cove. The most noted private normal school is the Hampton normal and agricultural institute for colored youth and Indians. Most of these schools are endowed and in a prosperous condition. A university was endowed at Henrico in 1619, and an *Academia Virginiensis et Oxoniensis* planned in 1621, but both came to naught. In 1691 the Colonial Assembly sent a man to England to secure a charter for a college. The Attorney-General objected, and when the petitioner remarked that the colonists had souls to save, he roared, "Souls! Damn the souls! Make tobacco." Nevertheless the charter was given, and the college of William and Mary established. The principal universities, colleges, and professional schools in the states are: The Univ. of Virginia, near Charlottesville (see Virginia, University of): Washington and Lee univ., Lexington; Emory and Henry coll. (M. E., South), Emory; Hampden-Sidney coll. (Presb.), Hampden-Sidney; Randolph-Macon coll. (M. E., South), Ashland; Richmond coll. (Bap.), Richmond; Roanoke coll. (Luth.), Salem; the Virginia military institute, at Lexington; the Hampton normal and agricultural institute (non-sect.), Hampton; Bridgewater college (Bapt.), Bridgewater; New Market polytechnic institute (non-sect.), New Market; Richmond theological seminary (Bapt.), Richmond; Curry coll. (Bapt.), Longfield; Protestant Episcopal theological seminary, Seminary Station; Bishop Payne divinity school (P. E.), Petersburg; the Union theological seminary (Presb.), at Hampden-Sidney (whence it was decided in 1896 to remove it to Richmond); and the Medical Coll. of Virginia, at Richmond. Industrial training is given at Hampton and at the Miller manual labor school at Crozet. There are a number of public libraries containing over 10,000 volumes, the state library at Richmond having over 60,000 volumes. The newspapers and periodicals, 1897, numbered 270.

Government, etc.—The constitution gives the right of voting to every male citizen of the United States 21 years old who has resided in the state one year, and in the co., city, or town, in which he offers to vote three months next preceding any election. A capitation tax of $1 is levied on all citizens 21 years of age, but payment is not a condition of suffrage. Persons entitled to vote and hold office, and none others, may sit as jurors. The gov., who receives a salary of $5000, and lieut.-gov. are elected by the people every four years. The sec. of state, treasurer, and auditor of public accounts are elected every two years by a joint vote of the general assembly. This assembly or legislature consists of a senate of 40 members elected for four years, and a house of 100 representatives elected for two years, each receiving $4 per diem. The sessions, which are biennial, meet on the first Wednesday in December, and are limited to ninety days, unless extended by special vote. The judicial power is vested in a supreme court of appeals, consisting of five judges, elected by the legislature, holding office 12 years and receiving $3000 salary each, circuit-courts, and county courts. By laws of 1877 the real and personal property of a married woman, owned at the time of marriage, is not liable to the control of her husband, or for his debts. As amended by acts of 1878, ownership and liability are made two distinct rights. The husband cannot be held for his wife's ante-nuptial debts. Wilful desertion for five years is cause for divorce. A local option liquor act was passed in 1886. The registration of voters is required in this state. In 1894 a modification of the Australian ballot system, known as the Walton system, went into effect.

The electoral votes have been cast as follows: 1788, Washington, 10, vice-p. scattering; 1792, Washington and Clinton, 21; 1796, Jefferson, 20, vice-p. scattering; 1800, Jefferson and Burr, 21; 1804, Jefferson and Clinton, 24; 1808, Madison and Clinton, 24; 1812, Madison and Gerry, 25; 1816, Monroe and Tompkins, 25; 1820, Monroe and Tompkins, 25; 1824, Crawford and Macon, 24; 1828, Jackson and Calhoun, 24; 1832, Jackson and Van Buren, 23; 1836, Van Buren and Smith, 23; 1840, Van Buren, 23, vice-p. scattering;

1844, Polk and Dallas, 17; 1848, Cass and Butler, 17; 1852, Pierce and King, 15; 1856, Buchanan and Breckenridge, 15; 1860, Bell and Everett, 15; 1864 and 1868, *no vote;* 1872, Grant and Wilson, 11; 1876, Tilden and Hendricks, 11; 1880, Hancock and English, 11; 1884, Cleveland and Hendricks, 12; 1888, Cleveland and Thurman, 12; 1892, Cleveland and Stevenson, 12; 1896, Bryan and Sewall, 12.

FINANCES.—The state debt, according to the United States census report of 1890, amounted to $34,227,234; the county debt, $1,774,535; municipal debt, $14,835,546; and the total combined debt, less the sinking fund, was $50,837,315. The total assessed valuation was $362,422,741. In 1896 the assessed valuations were, real estate, $304,204,590; personal, $94,341,046; total, $398,545,636; tax rate, $4 per $1000; in 1897 the total debt was $24,247,722. For important chapters in the financial history of the state, see REFUNDERS; REPUDIATION; BOND, STATE.

STATE INSTITUTIONS, ETC.—The penitentiary is at Richmond, and in the vicinity of that city is a soldiers' home. There are asylums for the insane at Staunton, Williamsburg, and Marion, and at Petersburg. The agricultural and mechanical coll. at Blacksburg has been well-equipped. There is an asylum for the deaf, dumb, and blind at Staunton, and an industrial reform school for white boys at Laurel. The National Guard, or Virginia volunteers, has an authorized strength of 5104 officers and men, and an actual strength of over 2600. There is also a considerable body of colored infantry. The total available force of the state in time of war is over 246,000.

UNITED STATES INSTITUTIONS.—The most interesting of these are Fort Monroe, begun in 1819 by Gen. Bernard, a former aide-de-camp to Napoleon, and costing nearly $3,000,000; the Gosport navy yard, founded by the British before the revolution, and owned by this country since 1801; the old single turret monitors, laid up in the James river just below Richmond; and the national cemeteries at Arlington, Alexandria, Richmond, Hampton, Fredericksburg, and other places.

POPULATION.—1790, 747,610—292,627 slave, 12,866 free col'd; 1810, 974,600—392,516 slave, 30,570 free col'd; 1840, 1,239,797—448,987 slave, 49,842 free col'd; 1860, 1,596,318—490,865 slave, 58,042 free col'd; 1870 (West V. having been set off), 1,225,163—512,841 col'd; 1880, 1,512,565—631,707 col'd. The population in 1890 was 1,655,980; rank of state in pop., 15. There are 100 cos.; for pop. 1890, see Census Tables, Vol. XV. The largest city is Richmond; pop. 1890, 81,388. At the same date Norfolk had a pop. of 34,871; Lynchburg, 19,709; Petersburg, 22,680; Alexandria, 14,339, and Portsmouth, 13,268. See histories by Campbell (1860); Cooke (1884); Kercheval's *History of the Valley of Virginia.*

VIRGINIA CITY, city and co. seat of Storey co., Nev.; on the Virginia and Truckel railroad; 15 miles n.e. of Carson City, the state capital. It is built on the e. slope of Mount Davidson, a peak of the Washoe range of the Sierra Nevada, seamed by the operations on the rich silver mines, about 6339 ft. above the level of the sea. It contains the Comstock lode, with ores about $\frac{1}{3}$ value of gold, and $\frac{2}{3}$ of silver, discovered in 1859 by a Virginian, hence the name of the city. In this mine is the famous Sutro tunnel, nearly four miles long. Virginia City also contains the Big Bonanza, or Consolidated Virginia, and the California mine. The buildings in Virginia City are principally of stone and brick; the streets are broad, graded at great expense, and without trees. It has many fine residences, is lighted with gas and electricity, and supplied with water from springs at the summit of the Sierra Nevada conducted through iron pipes. It contains a court-house, a Roman Catholic school, agencies of the Nevada bank of San Francisco, and bank of California, churches, theaters, daily and weekly newspapers, public schools, co. and St. Mary's hospitals, high school and miners' union libraries, and St. Mary's school (R. C.). Pop. '90, 8511.

VIRGINIA CITY, a city in s.w. Montana, settled 1863, incorporated 1865; co. seat of Madison co., and capital of the territory until 1875, when the seat of government was removed to Helena. It is situated on the e. slope of the Rocky mts. 110 m. in a direct line from Helena; pop. '90, 675. It is built in Alder gulch, 16 m. long, 5713 ft. above the level of the sea, in the center of a rich gold mining district. In the first 8 years after the discovery of gold in 1863, $30,000,000 worth of gold was taken from this vicinity. Other mineral products are silver, limestone, gneiss, galena, and serpentine. It is connected with Deer Lodge on the Montana Union railroad and with Dillon on the Union Pacific, by stage lines. It has a court-house, jail, churches, a newspaper, a bank, and graded schools. In the vicinity are hot springs with medicinal qualities.

VIRGINIA, UNIVERSITY OF, near Charlottesville, Albemarle co., Va., and 4. m. from Monticello, the home of Thomas Jefferson, who planned and organized it. It was chartered by the state in 1819 and opened in 1825. It is governed by a rector and 9 visitors. In this institution there is no curriculum or prescribed course of study to be pursued by every student. In establishing it, Mr. Jefferson, for the first time in America, threw open the doors of a university in the true sense of the name, providing, as amply as the available means would permit, for thorough instruction in independent schools in all the chief branches of learning, assuming that the opportunities for study thus presented were privileges to be voluntarily and eagerly sought, and allowing students to select for themselves the departments to which they are led by their special tastes and proposed pursuits in life. No honorary degrees are conferred. The course of study embraces—1. A literary and scientific department. 2. A medical department. 3. A law department. 4. An engineering department. 5. An agricultural

department. The library, open to the students, contains about 40,000 vols. The Brooks museums of natural history, consisting of well-selected cabinets of zoology, mineralogy, and geology, and a botanical collection, are arranged in a handsome building, and furnish ample illustration in their several departments. There is a well-appointed infirmary connected with the university for the care and comfort of sick students. Every student on admission deposits the infirmary fee, which entitles him, in case of sickness during the session, to the advice and attention of the infirmary physicians, and, if necessary, to nursing by professional nurses, without additional charge. Attendance on religious services is purely voluntary. The university has productive funds amounting to $262,000. In 1896 the number of professors and instructors was 48; students, 528. Dr. P. B. Barringer, LL. D., was chairman of faculty.

VIRGINIAN CREEPER. See VITACEÆ.

VIRGINIAN QUAIL, or COLIN, *Ortyx,* a genus of birds of the family *tetraonidæ* closely allied to quails and partridges, but differing from both in having a shorter and thicker bill, and a rather more lengthened tail. They are all natives of America. The best-known species is the VIRGINIAN COLIN (*O. Virginiana*), which is abundant in most parts of North America, and in some parts is commonly known by the name of quail, in others by that of partridge. In size it is intermediate between the common quail and the common partridge of Britain. The prevalent color of the plumage is brownish-red, the under parts whitish; but all parts are more or less mottled with different colors. The feathers of the head are capable of being erected into a sort of crest. The call of the male is popularly regarded as resembling the words, *Ah, Bob White!* The coveys of the Virginian quail often approach houses in winter, and mingle with domestic poultry. Great numbers are killed by guns and taken in snares; and in the western and southern states many hundreds are often caught in a day by parties of men on horseback, who drive the coveys into a great cylindrical net. This bird is easily domesticated, and seems well fitted for the poultry-yard. It has been introduced into some parts of Europe, and may almost be regarded as naturalized, although still rare in England.—There are several other species of the genus in Mexico, California, and the n.w. of America, of which one, the CALIFORNIAN COLIN (*O. Californica*), is remarkable for its long and beautiful black crest.

VIRGIN ISLANDS, a group of islands in the West Indies, partly belonging to Denmark, partly to Britain, directly e. of Puerto Rico. The islands and islets are about 50 in number, but of these, only a few are of any considerable size or importance. The total area is about 267 square miles, and the population is 39,000. Three of the islands, St. Thomas (q.v.), St. Croix (q.v.), and St. John, belonging to Denmark, have a total area of 118 square miles, and a population of (1890) 32,786. Spain claims Vieque and Culebra (together 64 sq. miles), the former of which has 3500 inhabitants and the latter is uninhabited. The others are British; total area 58 sq. miles; pop. about '81, 5287; '91, 4639. The chief of the British islands are Tortola, Virgin-Gorda, and Anegada. The chief town is Roadway in Tortola island, with an estimated pop. 400. The characteristic physical features are rugged heights and precipitous coast-lines, marked by numerous bays, havens, and creeks. Extensive tracts of land, possessed by the emancipated blacks, are covered with guinea-grass, which forms good pasturage for cows, sheep, and goats. A valuable mine of copper has been worked at Virgin-Gorda; and gold, silver, and other valuable minerals are said to have been found; but the inhabitants obtain their livelihood chiefly by wrecking. Cotton and sugar are cultivated in small patches, and form, with ginger and indigo, the principal products.

VIRGIN MARY. See MARY.

VIRGIN'S BOWER. See CLEMATIS.

VIRIATHUS, a Lusitanian (i.e., Portuguese) patriot, who energetically strove to prevent his country from falling under the dominion of the Romans. He flourished in the 2d c. B.C. Originally a shepherd, he afterward became a guerrilla chief, and appears to have supported himself (like many of the Lusitanian borderers) by predatory excursions into the neighboring Spanish territory. This mode of life brought him into collision with Rome, and in the year 151 B.C., the proprætor, Ser. Galba, was ordered to invade the country, and reduce the Lusitanians to subjection. By an act of detestable treachery Galba succeeded in destroying a large body of the natives; but the few who escaped (among whom was Viriathus) were inspired with the most implacable animosity toward the Romans, and immediately proceeded to rouse the patriotic passions of their countrymen. Viriathus soon rose into prominence. At first he kept mainly to the mountains, and contented himself with harassing the enemy by sudden and fierce descents, but in 147 (having been formally chosen leader in a season of great peril) he gave battle to Vetilius, the Roman proprætor, near Tribola (a town of Lusitania, s. of the Tagus), and inflicted on him a severe defeat. In the course of the next two years he repeatedly came off victorious in conflict with Roman armies; until in 144 the consul, Q. Fabius Æmilianus, encountered him in Andalusia with a large army of 15,000 foot and 2,000 horse, and Viriathus was driven back into his native fastnesses. But the Spanish tribes themselves now broke out in insurrection against their foreign masters; and after 143 the Romans had both a Numantine and a Lusitanian war to wage. The

general sent against Viriathus was the proprætor, Q. Pompeius, who, after a slight temporary success, was utterly crushed at the "hill of Venus," and forced to take refuge at Corduba (in Andalusia), while the conqueror wasted all the country round the Guadalquivir. Next year (142), the Romans were more fortunate. Q. Fabius Servilianus, consul, conducted the war, and succeeded in driving Viriathus once more out of Spain, and in annihilating several guerrilla bands; but in 141 a terrible reverse befell him near Grisane, when the whole of his army was hopelessly surrounded in a mountain-pass, and the story of the Caudine Forks (q.v.) was repeated, by its unconditional surrender. Viriathus, like Caius Pontius, showed a noble magnanimity in his hour of supreme triumph; he allowed his captives to go away free and unhurt on condition of Servilianus allowing the Lusitanians to retain their independence, and accepting their alliance. His terms were accepted, and the Portuguese patriot seemed to have triumphed over his colossal adversary; but in 140 the consul, Q. Servilius Cæpio (brother of Servilianus), having received the command in Further Spain, suddenly and treacherously resumed the war against Viriathus, and fearing lest he should not succeed in fair fighting, bribed some Lusitanian envoys (who had been sent to him by Viriathus with offers of peace) to murder their master, which they did while he lay sleeping in his tent. The death of this heroic chief was practically the ruin of Lusitanian independence; for though the followers of Viriathus elected another leader in his place, and strove to carry on the war, they could scarcely maintain themselves in the field for the rest of the year, and were then glad to acknowledge the supremacy of the Romans.

VIRTUAL VELOCITY. See WORK.

VI'RUS (the Lat. for a *poisonous liquid*) is a term used in medicine to signify those mysterious poisonous agencies which produce zymotic diseases (q.v.), such as small-pox, measles, scarlatina, the various forms of continued fever, ague, whooping-cough, cholera, syphilis, glanders, hydrophobia, etc. While each of these morbid poisons (as they are frequently called) has a definite and specific action, they collectively obey certain laws. For example (1.), their actions are variously limited, some affecting only one organ or system of organs, while others involve two or more organs or system of organs. Thus, in bronchocele or goiter, we have an example of a poison acting only on the thyroid gland, while in whooping-cough and hydrophobia all the organs supplied by the pneumogastric nerves (q.v.) are affected, and, in paludal or malarial poison most of the organs. (2.) Morbid poisons, like medicines and ordinary poisons, have their period of latency, which, however, here is usually much prolonged. While a medicine, e.g., is seldom longer than a few hours in exhibiting its effects, the poisons of scarlatina, measles, and small-pox remain latent in the system for at least seven, ten, and sixteen days respectively; while that of paludal fever and hydrophobia may be dormant for a year or upward. (3.) When several tissues or organs are acted on, the actions may be simultaneous, but are more commonly consecutive, a considerable interval often elapsing between the attacks. (4.) Another law of morbid poisons is, that two may co-exist in the same person; for example, small-pox and cow-pox have often been seen at the same time in the same person. In this case, each disease runs its course unaffected by the other; but most commonly, when two co-exist, one lies latent while the other runs its course. Thus, a case of intermittent fever may suddenly subside, and small-pox make its appearance; on recovery from this disease the intermittent fever may return.

Among the peculiarities presented by morbid poisons, the following points must be noticed: (1.) In experiments made on the inoculation of the small-pox virus by Dr. Fordyce, it was found that extremely diluted poison, if it acted at all, produced the same effects when introduced into the system as the concentrated virus. Hence it may be inferred that the intensity of the disease is not proportional to the amount of virus received into the system. (2.) Women in child-bed may not only engender a special poison of this class—that of puerperal fever—but are highly susceptible of these poisons, and almost always succumb to their action. (3.) Another peculiar law of morbid poisons, and one wholly unknown in medicinal substances, is, as Dr. Aitken remarks, "the faculty which the human body possesses of generating to an enormous extent a poison of the same nature as that by which the disease was originally produced. A quantity of small-pox matter not so big as a pin's head will produce many thousand pustules, each containing fifty times as much pestilent matter as was originally inserted; and the miasmata secreted by one child laboring under whooping-cough are sufficient to infect a whole city." A remarkable illustration of the development of syphilitic poison from a single infant over a whole province is given in the article SYPHILIS. (4.) A still more remarkable fact is, that many of these morbid poisons possess the property of seldom occurring more than once in the life of the same individual. This is the case with scarlatina, measles, small-pox, whooping-cough, and (to a less extent) typhoid and typhus fevers. (5.) This class of poisons is powerfully influenced by climate, and probably by the nature of the soil. Thus, the severe forms of typhus so common in Great Britain are hardly known in warmer climates, and the influence of cold weather on cholera and plague are well known. See TYPHUS: ZYMOTIC DISEASES. For the well-established theory that attributes a large number of diseases (including chicken-cholera, splenic-fever, perhaps phthisis, cholera, and yellow fever) to microbes or specific bacilli (small organisms), see GERM THEORY: MICROBES.

VISCHER, Friedrich Theodor, b. Germany, 1807; educated at Tübingen, where he studied theology. He soon devoted himself to æsthetics and philosophy, and after travels in Italy and Greece, became professor of æsthetics at Tübingen in 1844, and remained there with the exception of the years 1855–66, when he lived in Zürich. His principal book is his *Æsthetik* (1848–58). He d. 1887.

VISCONTI, a Lombard family which rose to sovereign rank in northern Italy in the 13th c., and was equally distinguished by the share it took in the political contests of the middle ages, and by the services which it rendered to literature and science. The name Visconti is derived from the Latin *vicecomites,* and at first was merely the title of an office, but it gradually became a family surname, though when it came to be applied to this family authentic history fails to explain. The family descended, according to tradition, from Desiderius, the last king of the Lombards, and belonged to the feudal nobility of northern Lombardy, having large estates near lakes Como and Maggiore. The first who appears prominently in history is Ottone, who became, in 1078, viscount of the archbishopric of Milan. The great Lombard families having, in course of time, split up into a multitude of lines, each in possession of a petty sovereignty, the Visconti on this account rose into comparative importance, more especially when, in 1262, another Ottone was appointed archbishop of Milan by pope Urban IV. This appointment being considered by the people an infringement of the rights of the chapter, was opposed by them; and their leader, Martino della Torre, and his successors, kept possession of the property of the see, and forced the archbishop to exile himself for 15 years. At last, the exiled Ottone advanced at the head of a body of exiles and emigrants upon Milan, defeated and captured his rival in a bloody and desperate conflict near Desio (Jan. 21, 1277), and entered the city amid the acclamations of the people, who hailed him as archbishop and perpetual lord of Milan. But he was not permitted to enjoy his newly-acquired dignities undisturbed, for, during the eleven years of his temporal sovereignty, he was engaged in almost uninterrupted warfare with the Torriani; and the contest was continued by his grand-nephew Matteo, who was chosen "captain of the people" in 1288. Ottone continuing in the archbishopric till his death in 1295. Matteo proved himself a prudent and temperate ruler, and his influential position was recognized by the emperor Adolf, who created him imperial vicar in Lombardy. Expelled by the Torriani and their allies in 1302, he was restored in 1311 by the aid of the emperor Henry VII., and reappointed imperial vicar in consideration of the payment of 40,000 florins; and Pavia, Alessandria, Tortona, Cremona, Bergamo, Lodi, etc., having been forced to acknowledge his authority, the family became more powerful than ever. Unfortunately, however, a quarrel arose with pope John XXII. regarding the appointment to the Milan archiepiscopate; and Matteo, obstinately refusing to yield to the papal pretensions, was condemned as a confirmed heretic, and himself and his descendants stigmatized as perpetually infamous (Mar. 14, 1322). The people, despite their profound esteem and affection for their ruler, were horror-struck at this solemn denunciation; and the feeling that so many of his friends were falling away from him so preyed on Matteo's mind, that he died in June, 1322, three months after his excommunication. His son, Galeazzo I., was chosen his successor, and immediately the pope proclaimed a religious crusade against the heretical Visconti, and the "holy army" under Raymond of Cardona advanced in 1323, on Milan, committing the most horrible ravages during its march. But though the Visconti could not directly oppose such an overwhelming force, Galeazzo's brother Marco, an able and experienced warrior, hovered round the disorderly host, cutting off detached parties; and the emperor Lewis (of Bavaria) having sent a body of troops to aid the Visconti, the crusaders were driven back, totally defeated at Vavrio on the Adda (1324), and the remnant, with their leader Cardona, captured. Soon after, Galeazzo, by the intrigues of his ambitious brother Marco, was perpetually exiled, yet his eldest son, Azzo V., succeeded him, while Pope Nicolas confirmed the third son, Giovanni, in the archiepiscopate—events which led Pope John XXII., for the sake of maintaining some authority over Milan, to recall the excommunication he had pronounced against the Visconti. Azzo was the greatest prince of the race, and ruled Milan wisely and well; devoting his attention to the improvement and esbellishment of the city, in which labor he was aided by the painter Giotto (q.v.) from Florence, and the sculptor Balducci from Pisa. As great in war as in peace, he extended his sway over almost the whole of Lombardy; and on his death in Aug., 1339, 3,000 citizens of Milan voluntarily assumed the garb of mourning. The council-general of Milan elected his two uncles, the archbishop Giovanni and Lucchino, as joint rulers in his stead; and on the latter, who was an able, resolute, and unscrupulous prince, wholly devolved the cares of the temporal sovereignty. Under his sway, Montferrat was added to the dominions of the Visconti; Pisa became tributary; a regular police was established; all offenders were punished with impartial severity; and a summary judgeship of appeals (*exgravator*), open only to foreigners to prevent party bias, was established. But the vices of suspicion, lust, and revenge threw a deep gloom over Lucchino's eminent qualities, led him into the commission of many cruel and tyrannical acts, and indirectly caused his own death by poison in Jan., 1349. From this time, the mild and peaceful archbishop reigned alone, availing himself of the assistance of his nephews in the more arduous tasks of government. He purchased Bologna for 200,000 florins in

1350; in 1353 accepted the lordship of Genoa, which had been almost crushed by its rival, Venice; and taking up the quarrel of his new subjects, equipped a fleet which, under Paganino Doria, gained a complete victory over the Venetians. He was the generous patron and friend of Petrarch, and the last good prince of the Visconti family. His three nephews conjointly succeeded him in Oct., 1354; but in 1355 the eldest had died of poison, and his dominions were shared between the other two, GALEAZZO and BARNABO. Both princes were men of pre-eminent ability, but irreclaimably vicious, the latter being a very monster of cruelty. Bologna, which belonged to Barnabo, fell into the hands of the pope, who excommunicated Barnabo for attempting to recover it; but the Visconti prince laughed at the Holy Father's curse, and swore that he would be both pope and emperor in his own dominions. Innocent VI. then sent legates to him to propose terms, but the young savage compelled the unfortunate messengers to tear their master's bulls to fragments, and swallow them piece by piece. One of the legates, on becoming pope as Urban V., took revenge by proclaiming a crusade against Barnabo, which was joined by all the principal Italian princes; the Romagna and the borders of Lombardy were desolated by a long desultory strife; and though Barnabo was ultimately forced to accept a sum of money in place of Bologna, he took a humorous revenge on his ecclesiastical antagonists by compelling the clergy in his dominions to pay all the expenses of the war. One act of his, however, may be mentioned with commendation; he issued an edict forbidding even the mention of the names of "Guelf" and "Ghibelline" under pain of having the tongue cut out; and his well-known stern adherence to such promises put an end to this long and mischievous controversy. His brother Galeazzo, who had established his residence at Pavia, was the "Mæcenas" of his time; he steadily befriended Petrarch; founded, under his direction, the university of Pavia; and collected a considerable library. The invention known as "Galeazzo's Lent," a system of torture calculated to prolong the victim's life for 40 days, stamps him with the family character of cruelty. On Galeazzo's death, his son, GIAN-GALEAZZO, succeeded (1378) him in Pavia and its dependencies; and by treacherously seizing and imprisoning his uncle, Barnabo of Milan, became sole ruler of Lombardy. He had all the great qualities and most of the vices of his race, and openly aspired to the sovereignty of Italy; conquering Padua, Verona, Vicenza; extending his dominions to the gates of Florence, which he also attacked; and purchasing from the emperor Wenceslas the absolute sovereignty of his dominions; with the title of *duke of Milan*, for 100,000 gold florins. This curtailment of the empire, however, displeased Germany, but the palatine Ruprecht, who invaded Lombardy, received such a lesson from the condottieri of Alberico da Barbiano at Brescia as caused him to gladly seek the n. side of the Alps. Florence, the only remaining obstacle to the accomplishment of the ambitious Visconti's scheme, was on the point of surrendering, when Gian died of the plague in 1402. He was a great patron of letters and science, gathered eminent men of all classes around him, reorganized the university of Piacenza, established a magnificent library, constructed the famous bridge over the Ticino at Pavia, and commenced the erection of the cathedral of Milan. His daughter, Valentina, married Louis, the younger brother of Charles VI. of France, and became grandmother of Louis XII., who upon this relationship founded his claims to the Milanese. His sons, GIAMMARIA VISCONTI (Giovanni-Maria) and FILIPPO MARIA VISCONTI, reigned in succession; but the former, who was cowardly, suspicious, and of a cruelty partaking of insanity, was, in the interest of his subjects, stabbed to death, May 16, 1412; and the younger brother, equally timorous and suspicious, and of only average cruelty, became sole ruler. The Venetians on the e., the marquis of Montferrat on the w., and the pope on the s., were rapidly curtailing his dominions, when, by a happy stroke of policy, he espoused Beatrice di Tenda, the widow of a condottieri leader, and thus obtained the services of a veteran band of soldiers. His fortunate choice of Carmagnola (q.v.) as his general led to the restoration of the former boundary line of his dominions; and on his quarrel with the soldier who had served him so well, he was sagacious enough to supply his place by others as nearly equal in ability as could be obtained. In 1441 he engaged the services of Francesco Sforza, to whom he gave his natural daughter Bianca in marriage; and on his death in 1447, the Visconti family was succeeded by that of Sforza (q.v.) in the lordship of the Milanese. Collateral branches of the Visconti still exist in Lombardy. See Lilla's *Famiglie Celebri Italiane*, Verri's *Storia di Milano*, and Muratori's *Annali de Italia*.

VISCONTI, a family of archæologists and architects, the first of whom to rise to prominence was GIOVANNI BATTISTA VISCONTI, a native of Sarzana, who settled at Rome, and, after making for himself a great name as an archæologist, succeeded Winckelmann as prefect of the antiquities of Rome. He was employed by Clement XIV. and Pius VI. to collect works of ancient art for the museum of the Vatican ("Museo Pio Clementino," as, from its two principal benefactors, it was called); and afterward, in 1778, commenced the writing of the letter-press which was intended to accompany the series of engravings of that splendid collection. He died in 1784.—ENNIO-QUIRINO VISCONTI, eldest son of the former, was born at Rome, Nov. 1, 1751, and was educated by his father, who intended him for the church. This profession, however, he afterward refused to adopt, and was for a time disowned by his father. But at last, in 1778, the old man was glad to call his

son to his aid, and together they prepared the first volume of the engravings of the *Museo Pio Clementino*. In 1784 he edited alone the second volume of the same series; he was also appointed conservator of the Capitoline museum. The series of engravings of the *Museo* was regularly issued, the seventh and last volume being published in 1807. When Rome fell into the hands of the French, Visconti became a member of the provisional government, and afterward one of the five consuls; but in Nov., 1799, the arrival of the Neapolitan army forced him to emigrate to France, and from this time he settled at Paris. His great reputation as an archæologist having been long recognized among the learned men of the French capital, he was made an administrator of the Louvre, and professor of archæology; and drew up a catalogue of the works of art in the new museum (many of the items being his old familiar acquaintances of the Vatican) which from the frequent raids of Napoleon on foreign collections, required to be frequently re-edited and enlarged. In 1804 he was requested by the emperor to select and publish a series of portraits of the distinguished men of ancient Greece and Rome; and this, probably the greatest of his works, appeared in two parts, *Iconographie Grecque* (3 vols. 4to, 1808) and *Iconographie Romaine* (1 vol. 4to, 1817). Contemporaneously, Visconti issued from time to time papers and dissertations on particular objects of ancient art. In 1815 he came to London by express desire of the British government, to fix a fair price for the Elgin marbles (q.v.), and on his return wrote a memoir explanatory of these sculptures. His last work was to complete his *Illustrazioni di Monumenti scelti Borghesiani* (Rome, 1821). He died after a long illness, Feb., 1818, and his death was a source of grief to the learned throughout Europe, many of whom came from great distances to attend his funeral. Besides his immense antiquarian knowledge, Visconti possessed an extensive acquaintance with the history, languages, mythology, and manners of the classic age. A complete collection of his works was commenced at Milan in 1818, but has not been completed. See *Antologia* of Florence, No. 18; Tipaldo's *Biografia degli Italiani Illustri;* and Maffei's *Storia della Letteratura Italiana.*—His younger brother, Filippo Aurelio, was also an eminent archæologist, and was president of the commission of antiquities and fine arts at Rome from 1809 to 1814. He edited the *Museo Chiaramonti*, a sequel to the *Museo Pio Clementino*, and published several other works; but his chief attention was bestowed upon numismatology. He died at Rome in 1830.—Louis Joachim Visconti, the son of Ennio Quirino, was born at Rome in 1797, and after a careful education at Paris, was apprenticed to an architect. His progress in his profession was rapid, as he was appointed an inspector of public buildings as soon as his apprenticeship had expired, and shortly afterward became one of the architects and surveyors of Paris, and architect of the Bibliotheque Royale in 1825. His works include various public monuments in honor of eminent Frenchmen, some of the first fountains of Paris, the tomb of Napoleon I., and various hotels and private residences, the chief of all being the plans for the completion of the Louvre on a most magnificent scale. Visconti died at Paris, Dec. 29, 1853.—The nephew of the preceding, Pierre-Hercules Visconti, is a celebrated archæologist and professor of archæology in the national academy of France, at Rome.

VISCOSITE, a name given by Professor Henry Wurtz to one of the constituents of the mineral *grahamite.* (See Irisite.) Viscosite forms from 15 to 20 per cent of this mineral, and also exists in some of the rock oil of Pennsylvania. It is obtained by digesting grahamite with ether or mineral naphtha, and distilling off the solvents. It is a translucent, dark brown, lustrous substance, having a peculiar balsamic odor, and being very brittle when cold. When warmed it acquires a viscosity like healing wax, and is very ductile. It appears to be a hydrocarbon free from oxygen.

VISCOUNT (Lat. *vice*, in place of, and *comes*, earl), originally the officer who acted as deputy to the earl, the earl being the king's immediate officer within his county. When the title of earl, originally personal, became hereditary, which took place in England under William the conqueror, a deputy had necessarily to be appointed in all cases where he was a minor, or otherwise incapacitated from discharging the duties of his office. This deputy gradually became a permanent officer, otherwise known as the sheriff, whose Latin designation continued to be *vicecomes.* The hereditary title of viscount is a degree of nobility unconnected with office. It was first granted in England to John Beaumont, created a peer by the title of viscount Beaumont in 1440. A viscount is now the fourth degree of nobility in the United Kingdom. His coronet consists of a chased circlet of gold, round which are ranged an indefinite number of pearls, nine of them being most generally shown, smaller than those of a baron's coronet, and in contact with each other. The mantle is scarlet, and has two doublings and a half of ermine. A viscount is styled "right honorable;" his wife is a viscountess; his eldest son has no courtesy title of peerage, but all his sons and daughters are styled "honorable."

VISCUM. See Mistletoe.

VISE (*escalier à vis*), a spiral or corkscrew staircase, the steps of which wind round and rest on a perpendicular pillar, called the newel (q.v.). In the Norman style, the steps rested on a spiral arch; but in later times, the steps were formed of single stones, stretching from the newel to the wall. This kind of staircase was that most generally used in mediæval buildings.

VISEU, an episcopal city of Portugal, in the province of Beira, stands in a wide, fruit-producing plain, at the height of 1770 ft. above sea-level, 46 m. n.e. of Coimbra. Its cathedral is a striking flamboyant edifice, and contains a number of excellent pictures by Gran Vasco, the Portuguese Fra Angelico. In the vicinity is the Roman camp, called Cava de Viriato. The town, which is one of the oldest in the country, contains other Roman as well as Gothic and Moorish remains. A large fair is held here. Pop. '90, 8360.

VISHNI-VOLOTCHEK, a t. of Russia, in the government of Tver, about 230 m. s.e. of St. Petersburg by railway. It is situated on the Tzna, on the Vishni-Volotchek water-route constructed by Peter the Great, and connecting the navigation of the Baltic and Caspian seas, by means of the Volga, etc. There is a very extensive transit-trade. An immense quantity of corn passes through the town every year. Pop. '80, 38,250.

VISHN'U is the second god of the Hindu triad, but is considered by his worshipers to be the supreme deity of the Hindu pantheon. See TRIMÛRTI and VAISHN'AVAS. The word is derived, by *S'ankara* (q.v.), in his commentary on the thousand names of Vishnu, and by other commentators after him, from *vish*, encompass, or *vis'*, penetrate; when, according to them, it would imply the deity who encompasses or penetrates the whole universe, both as regards its exterior appearance and its inward essence. A similar etymology is assigned to the word by *Yâska* (see NIRUKTA) in his gloss on the R'igveda; but as in this Veda, Vishnu does not yet embody the notions connected with him at the epic and Purânic period of Hinduism (see INDIA, sec. *Religion*), Yâska does not impart to the name the implied sense given to it by the commentators just mentioned. In the R'igveda, Vishnu is a representation of the sun, who "strides through the seven regions of the earth," and "in three ways plants his step" (or, as Yâska explains, plants his steps so as to become threefold). And, according to one predecessor of Yâska, these three steps mean the manifestation of the sun at its place of rising, on the meridian, and at its place of setting; or, according to another, its manifestation on earth, in the intermediate space, and in heaven; when—as a later commentator observes—in the first of these manifestations, Vishnu represents fire; in the second, lightning; and in the third, the solar light. From this position which Vishnu holds in the R'igveda (see VEDA), it results that he was not regarded there as supreme, or even as equal, to other deities, who, at the Vedic period, occupied a foremost rank. He is extolled in several hymns as having "established the heavens and the earth," as "being beyond mortal comprehension," and so forth; but he is there also described as having derived his power of striding over the world from *Indra* (q.v.), and as celebrating the praises of this god. He is frequently invoked together with the latter, but apparently always as inferior to him; and often, too, he occurs in company with a number of other gods, such as Varun'a, the Maruts, Rudra, Vâyu, the luminous deities called *Âdityas*, and others, without any distinction being drawn in their respective rank. Fewer hymns, moreover, are separately devoted to his praise than to that of Agni, Indra, or other prominent gods of the Vedic period; and it deserves notice, too, that at that period he was not yet included among the Âdityas, for only at the epic period, when the number of these deities, originally varying from six to eight, was raised to twelve, Vishnu was included in it—he then being named as the foremost of these luminous offsprings of Aditi, or space.

Although some of the Brâhman'as of the Vedas (q.v.) already show the progress which the solar Vishn'u had made in the imagination of the people, and although they contain the germ of several legends, which, at a later time, became fully developed, the really mythological character of this god, as the basis of the divine worship now paid him by a large class of the Hindu population, belongs to the epic poems—the *Râmâyan'a* and *Mahâbhârata* (q.v.)—and to the *Purân'as* (q.v.). In the Mahâbhârata, Vishn'u is often identified with the supreme spirit; but while in some portions of this poem—the different parts of which belong to different epochs of Hindu antiquity—he is thus regarded as the most exalted deity; he is again, in others, represented as paying homage to S'iva (q.v.), the third person of the Trimûrti, and as acknowledging the superiority of this god over himself. Taking, therefore, the Mahâbhârata as a whole, he does not occupy, in this epos, the exclusive supremacy which is assigned to him in the Râmâyan'a, and still more in those Purân'as especially devoted to his praise.

The large circle of myths relating to Vishn'u, in the epic poems and Purân'as, is distinguished by a feature which, though not quite absent from the mythological history of S'iva, especially characterizes that of Vishn'u. It arose from the idea, that whenever a great disorder, physical or moral, disturbed the world, Vishn'u descended "in a small portion of his essence" to set it right, to restore the law, and thus to preserve creation. Such descents of the god are called his *Avatâras* (from *ava* and *tr'î*, descend); and they consist in Vishn'u's being supposed to have either assumed the form of some wonderful animal or superhuman being, or to have been born of human parents, in a human form, always, of course, possessed of miraculous properties. Some of these Avatâras are of an entirely cosmical character; others, however, are probably based on historical events, the leading personage of which was gradually endowed with divine attributes, until he was regarded as the incarnation of the deity itself. With the exception of the last, all these Avatâras belong to the past; the last, however, is yet to come. Their number is generally given as ten, and their names in the following order: 1. The fish-; 2. The tortoise-; 3. The boar-; 4. The man-lion-; 5. The dwarf-; 6. The Paras'u-Râma-;

7. The Râmachandra, or, briefly, Râma-; 8. The Kr'ishn'a and Balarâma-; 9. The Buddha-; and 10, The Kalki- or Kalkin-Avatâra. This number and enumeration of Avatâras, however, was not at all times the same. The Mahâbhârata, though also mentioning ten names, successively the Hansa-, tortoise-, fish-, boar-, man-lion-, dwarf-, Paras'u-Râma-, Râma-, Sâtvata-, and Kalkin-Avatâras. The Bhâgavata-Purân'a speaks of twenty-two Avatâras of Vishn'u, which, for instance, also comprise Pr'ithu (q.v.), Dhanvantari, the god of medicine, and Kapila, the reputed founder of the Sânkhya (q.v.) philosophy. Other works have twenty-four Avatâras, or even call them numberless; but the generally-received Avatâras are those ten mentioned before, an idea of which may be afforded by the following brief account.

1. The *Matsya-* or *fish-Avatâra.*—When, at the end of the last mundane age, the Bhâgavata-Purân'a relates, Brahman, the first god of the Trimûrti, had fallen asleep, a powerful demon, *Hayagrîva,* stole the Vedas which had issued from the mouth of Brahman, and lay by his side. About that time, a royal saint, *Satyavrata,* had by his penance attained the rank of a Manu, and Vishn'u, who had witnessed the deed of Hayagrîva, and intended to slay him, assumed for this purpose the form of a very small fish, and glided into the hands of the saint when the latter made his daily ablutions in the river. Manu, about to release the little fish, was addressed and asked by it not to expose it to the danger that might arise to it from the larger fish in the river, but to place it in his water-jar. The saint complied with its wish; but in one night the fish grew so large, that at its request he had to transfer it to a pond. Yet soon the pond also becoming insufficient to contain the fish, Manu had to choose a larger pond for its abode; and, after successive other changes, he took it to the ocean. Satyavrata now understood that the fish was no other than *Nârâyan'a* or Vishn'u, and, after he had paid his adoration to the god, the latter revealed to him the imminence of a deluge which would destroy the world, and told him that a large vessel would appear to him, in which he was to embark together with the seven Rishis, taking with him all the plants and all the seeds of created things. Manu obeyed the behest of the god: and when the water covered the surface of the earth Vishn'u again appeared to him in the shape of a golden fish with a single horn, 10,000 miles long; and to this horn Manu attached the vessel, by means of Vishn'u's serpent serving as a cord. While thus floating in the vessel, Manu was instructed by the fish-god in the philosophical doctrines and the science of the supreme spirit; and after the deluge had subsided, the fish-god killed Hayagrîva, restored the Vedas to Brahman, and taught them to the Manu Satyavrata, who in the present mundane age was born under the name of *S'râddhadeva,* as the son of Vivasvat.—A fuller account of this Avatâra is given in the *Matsya-Purân'a,* where the instruction imparted to Manu by the fish-god includes all the usual detail contained in a Purân'a (q.v.), that relating to creation, the patriarchs, progenitors, regal dynasties, the duties of the different orders, and so forth. In the Mahâbhârata, where the same legend occurs, but without either that portion concerning Hayagrîva, or the instruction imparted by the fish, there is, besides minor variations, that important difference between its story and that of the Purânas, that the fish is not a personification of Vishn'u, but of Brahman, and that the deluge occurs in the present mundane age, under the reign itself of the Manu, who is the son of Vivasvat.—The origin of this Avatâra is probably a kindred legend, which occurs in the *S'atapathabrâhman'a,* of the White Yajurveda (see Veda); but there the fish does not represent any special deity, and the purpose of the legend itself is merely to account for the performance of certain sacrificial ceremonies.

2. The *Kûrma-* or *tortoise-Avatâra.*—When, of old, the gods felt their powers impaired, and were desirous of obtaining *Amr'ita,* the beverage of immortality, Vishn'u directed them to churn, together with the demons, the milk-sea, by taking the mountain *Mandara* for their staff, and his serpent *Vâsuki* for their cord, the gods to stand at the tail, and the demons at the head of the serpent; while he himself consented to support the mountain on his back, after having assumed the shape of a gigantic tortoise. The result of this churning of the sea of milk, was, besides the ultimate recovery of the Amr'ita, the appearance of a variety of miraculous things and beings; but it also led to a violent contest between the gods and demons, in which the latter were defeated. See Râhu.—The idea of the lord of creation assuming the shape of a tortoise, and that of sacrificial liquids, especially clarified butter, becoming tortoise-shaped (*Kûrma,* the word for tortoise, meaning literally, "badly or slowly going"), occurs also in the Yajurveda; but the legend on which the tortoise-Avatâra of Vishn'u is based seems to belong entirely to the post-Vedic period of Hinduism.

3. The *Varâha-* or *boar-Avatâra.*—It is supposed to have taken place when, at the period of creation, the earth was immersed in water, and Vishn'u, in order to raise it up, assumed the form of a gigantic boar. In the earlier recension of the *Râmâyan'a* and the *Linga-Purân'a,* it was Brahman, the creator of the universe, who transformed himself into a boar for rescuing the earth from its imperiled position; and in the *Black Yajurveda,* where this idea is first met with, it is likewise said that the lord of creation upheld the earth, assuming the form of a boar. At a later period, however, this Avatâra is generally attributed to Vishn'u. Between both conceptions there is, however, also this great difference, that in the former the transformation of the deity into a boar has apparently a purely cosmical character, whereas in the latter "it allegorically represents the extrication of the world from a deluge of iniquity, by the rites of religion."

(Wilson's translation of the *Vishn'u-Purân'a*, 2d ed., by F. Hall, vol. i. p. 59, note.) For the boar, as an incarnation of Vishn'u, is the type of the ritual of the Vedas. He is described as the sacrifice personified; his feet being the Vedas; his tusks, the sacrificial post to which the victim is tied; his teeth, the sacrificial offerings; his mouth, the altar; his tongue, the fire; his hairs, the sacrificial grass; his eyes, day and night; his head, the place of Brahman; his mane, the hymns of the Vedas; his nostrils, all the oblations; his snout, the ladle of oblation; his voice, the chanting of the Sâmaveda; his body, the hall of sacrifice; his joints, the different ceremonies; and his ears as having the properties of voluntary and obligatory rites (*Vishn'u-P.*, vol. i. p. 63); and similar descriptions of the boar occur in the Harivan's'a (q.v.) and elsewhere; besides those relating to the immense size and wonderful appearance of the mysterious animal. In the *Bhâgavata-Purân'a*, another legend is also connected with this incarnation of Vishn'u, still more distinctly proving that at the Purân'ic period, it was viewed in a purely religious light. According to this legend, *Jaya* and *Vijaya*, two doorkeepers of Vishn'u, once offended some Munis who claimed admission to the paradise of Vishn'u, and in consequence were doomed to lose their position in Vishn'u's heaven, and to be reborn on earth. They became thus the sons of *Kas'yapa* and *Diti*, under the names of *Hiran'yakas'ipu* and *Hiran'yâksha*. The former subdued the three worlds, and the latter went straight to heaven, to conquer also the gods. Thus threatened in their existence, the gods implored the assistance of Vishn'u; and Vishn'u, who at that period was the mysterious or primitive boar, slew Hiran'yâksha. A similar contest between Vishn'u as boar and numerous demons, the progeny of Diti, always ending in the defeat of the latter, is also described in the *Mokshadharma*, one of the later portions of the Mahâbhârata; and from this and similar descriptions, it follows that the boar-Avatâra had gradually lost its original character, and assumed that common to the remaining Avatâras, of representing the deity as become incarnate, for the purpose of remedying moral or religious wrong, or of destroying influences hostile to the pretensions of the Brâhmanic caste.

4. The *Nr'isinha-* or *man-lion-Avatâra.*—*Hiran'yakas'ipu*, the brother of the demon Hiran'yâksha just mentioned, had resolved to become a sovereign of the three worlds, and exempt from death and decay. To attain this end, he practiced severe austerities, and ultimately received from Brahman, as the desired reward, a promise that he should become a supreme ruler, and death should not accrue to him from any created being, neither within his abode nor without, neither by day nor by night, neither in heaven nor on earth, nor by any kind of weapon. Possessed of the grant of this boon, he now gave course to the hatred he had conceived against Vishn'u for having killed his brother Hiran'yâksha. He oppressed all the gods, robbed them of their shares in the sacrifices, and threatened their destruction. But he had a son, *Prahrâda* or *Prahlâda*, who, through his religious studies and pious conduct, had become a devout worshiper of Vishn'u. When Hiran'yakas'ipu became aware of his son's partiality for this god, he first endeavored to impart to him his own hostile feelings against Vishn'u, but failing in this, resolved to kill him. All the means, however, he employed to this end remained vain; and when at last, Hiran'yakas'ipu, about to cut off the head of his son, sneeringly asked him why Vishn'u, who, as he asserted, was everywhere, should not be present also in a pillar in the hall, which he struck with his fist, Vishn'u suddenly made his appearance in the shape of a being neither man nor animal, in that of a man-lion of fearful aspect and size; and after a violent struggle with the demon, killed him in tearing his heart out with his finger-nails. Prahlâda was then installed by him as sovereign over the demons, and at the end of a pious reign, obtained final liberation.

5. The *Vâmana-* or *dwarf-Avatâra.*—Prahlâda's son was *Virochana*, and his son was *Bali*. The latter, after having conquered Indra (q.v.), ruled over the three worlds, and filled the gods with dismay for their future prosperity. They had, in consequence, recourse to Vishn'u; and when, at one time, Bali was celebrating a grand sacrifice, Vishn'u, assuming the shape of a dwarf, humbly approached the demon king. Pleased with the devout and unpretending appearance of the little Brâhman, Bali asked him to demand a boon, however costly it might be. The dwarf, however, merely asked for so much ground as he could measure with three paces. The king smilingly granted so modest a request, though his family priest *Us'anas*, suspecting the true nature of the dwarf, strongly dissuaded him from doing so. But when the dwarf had obtained what he asked for, he strode with one pace over the earth, with a second over the intermediate space (the atmosphere), and with a third over the sky, thus leaving for Bali only the subterranean regions, which he assigned him for his future abode. The demons endeavored to frustrate this result, after Vishn'u had taken his first two strides, but they were overcome by the followers of Vishn'u; and Bali, when resigning himself to his fate, in reply to a reproach addressed to him by the dwarf for trying to break his promise, uttered—according to the Bhâgavata-Purân'a—the following words, which may serve as one of many instances to show how sacred a promise was held by the Hindus when once given, and even though artfully obtained: "If, renowned chief of the gods, you consider the word which I uttered to be deceitful, I now do what is sincere, and can be no deception — place your third step on my head. Fallen from my position, I fear not the infernal regions, or binding in bonds, or misfortune difficult to escape, or loss of wealth, or your restraint, so much as I am

afflicted by a bad name." (See J. Muir's *Original Sanskrit Texts*, vol. iv. p. 128.) For his righteousness, he was then rewarded by Vishn'u with the promise, that after a temporary residence in one of the most delightful places of Pâtâla (q.v.), he should be born as the Indra, in the reign of the eighth Manu. In this incarnation as dwarf, Vishn'u is considered to have been a son of the same Kas'yapa who is also the father of Hiran'yakas'ipu and Hiran'yâksha; but while their mother is Diti, the dwarf's mother is Aditi (space); and since she previously had brought forth Indra, Vishn'u is sometimes called Upendra, or the younger or later Indra. As a son of Aditi, Vishn'u becomes one of the Âdityas (see before).—The Vedic conception of the three strides of Vishn'u, as mentioned in the beginning of this article, is doubtless the basis of the idea whence this Avatâra arose.

6. The *Paras'u-Râma-Avatâra*, or Vishnu's incarnation as Râma, the son of Jamadagni, armed with an axe (*paras'u*). *Arjuna*, a son of *Kr'itavîrya*, and king of the Haihayas, had obtained, as a reward for his piety, a thousand arms, and the sovereignty over the earth. The gods, frightened at his power, had recourse to Vishn'u, and the latter resolved to be born as a son of Jamadagni, that he might slay him. Jamadagni was the son of *R'ichîka*, of the race of Bhr'igu, a pious sage who had married *Ren'ukâ*, the daughter of king *Prasenajit*, and had obtained five sons by her, the last of whom was *Râma*, or Vishn'u incarnate in this form. Ren'ukâ having once, for some supposed impropriety, incurred the anger of her husband, was, at his bidding, killed by her son Râma, but at the request of the latter, again restored to life; and her first four sons were likewise saved from the consequence of the wrath of Jamadagni by the intercession of their brother Râma. After this event had happened, or, as one account goes, previously to it, Arjuna came to the hermitage of Jamadagni, and was there hospitably received by the saint, who could treat him and his followers sumptuously, as he possessed a fabulous cow of plenty, that not merely supplied him with the milk and butter required for his sacrificial offerings, but with everything else he wished for. Struck by the precious qualities of this cow, and in spite of the kind treatment he had met with, Arjuna carried off with him the cow and her calf. When Râma, who, on this occasion, had been absent from home, returned to the hermitage, and learned what had happened, he took up his axe (or, as the Mahâbhârata says, his bow), and slew Arjuna, together with his army. The sons of the latter, to revenge their father's death, after some time, attacked the hermitage, and succeeded in killing Jamadagni. Thereupon, Râma made a vow to extirpate the whole Kshattriya or military race; and not satisfied with destroying the sons of Arjuna, he killed every Kshattriya whom he encountered afterward. In this manner, the legend concludes, "he cleared thrice seven times the earth of the Kshattriya caste"—killing the men of so many generations as fast as they grew to adolescence—"and filled with their blood the five large lakes of Samantapanchaka, from which he offered libations to the race of Bhr'igu." He then performed a solemn sacrifice, and distributed the land and many riches among the ministering priests. The Mahâbhârata, which on two occasions relates this legend, in one place enumerates the Kshattriyas who escaped the destruction of their caste, and from whom the lines of the kings hereafter were continued; this account, however, is inconsistent with Purânic lists, in which the royal lineages are uninterrupted. There can be little doubt that a real historical conflict between the Brâhman'as and Kshattriyas underlies the conception of this Avatâra; one which has its parallel in the history of Vasisht'ha and Vis'wâmitra (q.v.).

7. The *Râmachandra-* or, briefly, *Râma-Avatâra.—Râvan'a*, a king of *Lankâ*, or Ceylon, a monster with ten heads and twenty arms, had, by dint of austerities, obtained from Brahman the promise that neither gods nor demons should be able to take his life. In consequence, he oppressed the whole universe: the sun dared not shine hot, or the fire burn, or the wind blow, where he stood, and the ocean, when it saw him, became motionless. The gods, thus seeing the world and their own existence endangered, implored Brahman to protect them; and he, remembering that the demon, when asking for the boon he had granted him, omitting to include men among the beings that should not hurt him, advised the gods to pray to Vishn'u to become incarnate. This they did, and Vishn'u granted their prayer. At that time, *Das'aratha*, a king of Ayodhyâ, of the solar line of Hindu kings, performed the great horse-sacrifice in order to obtain sons; for though he had three wives, *Kaus'alyâ*, *Sumitrâ*, and *Kaikeyî*, he was without male progeny. This sacrifice became successful, for, when on the point of completion, a supernatural being appeared to him with a divine beverage, one-half of which he was to give to Kaus'alyâ, one-fourth to Sumitrâ, and the remaining fourth to Kaikeyî. And as this nectar which he gave them contained the divine essence of Vishn'u, *Râma*, the son whom Kaus'alyâ brought forth, became one half, the twins *Lakshman'a*, and *S'atrughna*, born by Sumitrâ, together one-fourth, and *Bharata*, the son of Kaikeyî, another fourth, of the substance of Vishn'u. While Râma and his brothers were still boys, the sage *Vis'wâmitra* (q.v.) came to the court of Das'aratha, requesting him that he should allow Râma to proceed to his hermitage, in order to destroy there the Râkshasas, or fiends, who infested it, and disturbed his sacrificial rites. Though reluctantly, Das'aratha gave his consent to his departure; and Râma accompanied by his brother Lakshman'a—who, throughout his brother's career, ramained his faithful companion and ally—started on his first eventful journey; for it was marked by a number of won

derful exploits which he performed in killing the demons and which already then revealed his divine mission. Having fulfilled the desire of Viswâmitra, he proceeded to Mithilâ, where king *Janaka* held a great assembly of kings, having promised to give in marriage his daughter *Sîtâ* (q.v.) to the prince who would be able to bend the bow with which S'iva (q.v.) once conquered the gods at the sacrifice of Daksha, and which now was in his trust. Yet so large and heavy was this bow, that not even the strongest of them could so much as move it. But when Râma arrived, and the bow was shown him, he lifted it up and bent it, as it were in sport, and ultimately even broke it in the middle. Sîtâ became thus the wife of Râma; while Janaka gave *Urmilâ* to Lakshman'a, *Mân'd'avî* to Bharata, and *S'rutakîrtti* to S'atrughna. On his way home, Râma met *Paras'urâma* (see the sixth Avatâra) who, having heard of his namesake's bow-feat at the court of Janaka, challenged him to bend also the bow of Vishn'u, which he had received from his father, Jamadagni, and if he could do so, to a single combat. Râma, displeased with the doubt of Paras'urâma in his strength, immediately seized the bow, bent it, and would have killed the son of Jamadagni, had he not respected his quality as a Brâhman: still, he destroyed the worlds which the latter had acquired by his penance, and thus excluded him from heaven. (This account given of the meeting of the two Râmas, in the Râmâyan'a, would seem to show that at the time when this poem was composed, the *Paras'urâma* was not yet conceived as an incarnation of Vishn'u, since he is represented in it as jealous of the defeat which S'iva's bow had suffered at the hands of the son of Das'aratha.) After this event, Bharata, and his brother S'atrughna, were sent by their father on a visit to Bharata's maternal uncle, *As'wapati;* and Das'aratha, who was old, and desired to retire from the world, made all preparations for installing his eldest son, Râma, as heir-apparent to the throne of Ayodhyâ. But in this design he was frustrated; for, through the intrigues of *Manthará*, the hunchbacked nurse of Bharata, and his queen Kaikeyî, he was, in a weak moment, prevailed upon to grant any wish which the latter would ask of him; and Kaikeyî, availing himself of Das'aratha's rashly-given promise, demanded of him the installation of her own son, Bharata, as heir-apparent, and the banishment to the forest of Râma for a period of 14 years. A promise once uttered being irrevocable, and Râma having resolved not to cause a word given by his father to remain vain, neither the wishes of the people of Ayodhyâ nor those of Bharata and S'atrughna, who meanwhile had returned, and were enraged at what had occurred, could shake his determination to submit to his exile. Das'aratha died in consequence heart-broken, and Bharata assumed, till the return of Râma, the government of Ayodhyâ.

The long exile of Râma which now followed, and was shared in by his brother Lakshman'a, became, then, the source of the wonderful events which should hereafter lead to the destruction of the demon Râvan'a. They began with a series of conflicts which he had to sustain with the Râkshasas, who infested his forest abode, and which invariably, of course, ended in the destruction of these beings. One of these conflicts, however, was especially pregnant with the destiny he had come to fulfill. Râvan'a's sister, *S'ûrpan'akhá* (lit., a female whose finger-nails were like winnowing baskets), was one of those demons who haunted the woods. She fell in love with Râma, but was repelled by him; and when, in a fit of jealousy, she attacked Sîtâ, Lakshman'a cut off her ears and nose. Enraged at this treatment, she repaired to her brother Râvan'a, and in order better to stimulate his revenge, she also excited in him a passion for Sîtâ. Râvan'a therefore started off for the forest Dan'd'aka, where Râma lived; and, aided by another demon, Marîcha, who transformed himself into a golden-colored deer, and thus enticed both brothers away from the hermitage, to chase after it, succeeded in carrying off Sîtâ to his capital. By means of some other supernatural events then happening, Râma discovered the fate of his wife; and the remainder of his exile is now filled up with his preparing for war with Râvan'a, conquering and destroying him, and recovering Sîtâ, whose honor had remained untarnished during her long and severe trials when kept as a prisoner in the harem of Râvan'a. Some of the incidents of this struggle are of special interest, inasmuch as they are the basis of traditions still prevalent in India. They chiefly relate to the allies of Râma, who were no other than miraculous bears and monkeys, and by their magic powers mainly brought about the defeat of Râvan'a and his armies, while also helping him to communicate with Sîtâ during her captivity. All these bears and monkeys were of divine origin, produced at the behest of Brahman by the gods for the express purpose of becoming the allies of Râma. Thus, the bear-king, *Jámbuvat*, issued from the mouth of Brahman himself; *Bâli* was a son of Indra; *Sugríva*, of the Sun; *Tára*, of Vr'ihaspati; *Gandhamâdana*, of Kuvera; *Nala*, of Vis'wakarman; *Nîla*, of Fire; *Sushen'a*, of Varun'a; *S'arabha*, of Parjanya; and the most renowned of all, *Hanumat*, was a son of Wind. See the article HANUMÂN, where several of his feats are mentioned. They overbridged the sea, to carry their armies to Ceylon—whence the line of rocks in the channel is still called *Râmasetu*, or Râma's bridge—in the English maps, Adam's bridge; they brought large rocks from the Himâlaya to support the bridge—whence the numerous rocks scattered all over India are supposed to have arisen as they dropped down on their transport to the sea; and they performed similar other feats, still commemorated in festivals performed in honor of Hanumat and his tribe. As is the case in other Avatâras of Vishn'u, there is also in the Râma-Avatâra a personage who, though nearly related to the fiend doomed to destruc-

tion, acknowledges the divine nature of the incarnate god, and dissuades his friends from opposing him. In this Avatâra, such a personage is *Vibhishaṇ'a*, the uncle of Râvaṇ'a, whose counsel, however, is disregarded. Similarly disposed is also *Kumbhakarṇ'a*, the brother of Râvaṇ'a, who likewise understands that Râma is Vishṇ'u; but, as he yields to the orders of his brother, his fate is death. Vibhîshaṇ'a, however, in reward of his proper conduct, is, after Râvaṇ'a's death, placed on the throne of Ceylon. When, at the end of this fierce war, the time fixed for Râma's exile had expired, he returned to Ayodhyâ with Sitâ, whose purity had previously been tested by an ordeal of fire, and there received back from Bharata the sovereign power which, in the mean time, the latter had exercised in his stead; and at the end of a long and glorious reign, he became reunited with the splendor of Vishṇ'u. The story of this incarnation is briefly told in an episode of the Mahâbhârata (q.v.), and in several Purâṇ'as; with the fullest detail, however, in the *Râmâyaṇ'a* (q.v.). A copious abstract of the latter is given in the poem *Bhaṭṭ'ikâvya*. See SANSKRIT LITERATURE. The English reader may consult, for some further detail, an "Analysis of the Râmâyaṇ'a," in Prof. Monier Williams's *Indian Epic Poetry* (Lond. 1863).

8. The *Kṛ'ishṇ'a-Avatâra* and *Balarâma-Avatâra*.—The former of these two, which are generally treated as one, is the most interesting incarnation of Vishṇ'u, both on account of the opportunity which it affords to trace, in Hindu antiquity, the gradual transformation of mortal heroes into representatives of a god; and on account of the numerous legends connected with it, as well as the influence which it exercised on the Vaishṇ'ava cult (see VAISHṆ'AVAS). In the Mahâbhârata (as Dr. Muir has shown in the fourth volume of his excellent work, *Original Sanskrit Texts*), Kṛ'ishṇ'a—which literally means, "the black or dark one"—is sometimes represented as rendering homage to S'iva (q.v.), and therefore acknowledging his own inferiority to that deity, or as recommending the worship of Umâ (q.v.), the consort of S'iva, and as receiving boons from both these deities. In some passages, again, he bears merely the character of a hero endowed with extraordinary powers, and, in some, his divine nature is even disputed or denied by his adversaries, though they are ultimately punished for this unbelief. As the intimate ally of the Pâṇ'du prince, Arjuna (see PÂṆ'DAVAS), he claims, especially in the philosophical episode, the Bhagavadgîtâ, the rank of the supreme deity; but there are other passages, again, in the Mahâbhârata, in which the same claim of S'iva is admitted, and an attempt is made at compromising their rival claims by declaring both deities one and the same. Sometimes, moreover, Kṛ'ishṇ'a is, in this epos, declared to represent merely a very small portion—"a portion of a portion," as it is called—of the divine essence of Vishṇ'u. In the Mahâbhârata, therefore, which is silent also regarding many adventures in Kṛ'ishṇ'a's life, fully detailed in the Purâṇ'as, the worship of Vishṇ'u in this incarnation was by no means so generally admitted or settled as it is in many Purâṇ'as of the Vishṇ'uit sect; nor was there, at the epic period, that consistency in the conception of a Kṛ'ishṇ'a-Avatâra which is traceable in the later works. The principal legends relating to Kṛ'ishṇ'a, as he appears in the Harivaṃs'a and the Purâṇ'as, are the following: A demon king, *Kansa* of Mathurâ, of the race of Yadu, and therefore of the lunar line of kings, who, in a former birth, had been the demon *Kâlanemi*, had deposed and imprisoned his father, *Ugrasena*, and oppressed, with his iniquitous hosts, the Earth; and Earth having laid her complaints before an assembly of the gods on Mt. Meru, Brahman prayed to Vishṇ'u to relieve the world of its distress. When he had ended his prayer, Vishṇ'u plucked off two hairs, one white, and one black, and promised the gods that these two hairs should become impersonated as *Balarâma* and *Kṛ'ishṇ'a*, sons of Devakî, to fulfill their wishes. Now Devakî, who, in a former life, had been Aditi (space personified), was a wife of Vasudeva, who was of the race of Yadu, and a relative of Kansa; but as Kansa had been warned by a voice in heaven that their eighth child would be an incarnation of Vishṇ'u, he placed both husband and wife in confinement, after having obtained, though, from Vasudeva the promise that he would deliver to him every child Devakî would bring forth. Six children of hers were accordingly given up to Kansa, and destroyed; but when Balarâma, the seventh, was about to come into the world, Vishṇ'u appeared to *Yoganidrâ*, a form of Umâ (q.v.), and directed her to transfer Balarâma, before the time of his birth, to *Rohiṇ'î*, another wife of Vasudeva, and spread the report that Devakî had miscarried; enjoining her also to become incarnate as a child of Yas'odâ, the wife of an old cowherd Nanda, at the same time that he would become incarnate, as Kṛ'ishṇ'a, in the eighth conception of Devakî; for at the time of their simultaneous birth, he added, Vasudeva, aided by him, would bring the infant Kṛ'ishṇ'a to the bed of Yas'odâ, and her to that of Devakî. In this manner, *Balarâma* and *Kṛ'ishṇ'a* were saved, though the infant Durgâ, as soon as born, was dashed by Kansa against a stone, and suffered a temporary death. Kansa, having become aware that his design had been frustrated, now ordered the destruction of all young children, wherever they might be found, but considering it useless to keep Devakî and Vasudeva any longer in prison, liberated them. Vasudeva, apprehensive of the safety of Balarâma, then took him to Nanda, to be brought up together with Kṛ'ishṇ'a; and thus began the earthly career of these two Avatâras of Vishṇ'u, in which Balarâma always figures as the friend and ally of his more important brother, Kṛ'ishṇ'a. The first miraculous act of the latter consisted in causing the death of a female demon, *Putanâ*, who suckled, and meant to destroy him. Then, as a little boy, he overturned a heavy wagon of the cowherds,

and pulled down the trunks of two large trees—to the amazement of the cowherds, who did not yet suspect his divine nature, and, becoming afraid to remain any longer in Vraja, the place where these events happened, repaired to Vr'indâvan'a. There Balarâma and Kr'ishn'a remained until they had attained seven years of age. At this time Kr'ishn'a killed a serpent-monster Kâlîya, in the Yamunâ river, and then returned to Vraja. The next exploit of the brothers, more particularly, however, of Balarâma, consisted in the destruction of two demons, *Dhenuka* and *Pralamba*, who infested the forests; but that which followed, especially established the fame of Kr'ishn'a, and is one still commemorated in their festivals by the worshipers of this god. When sporting in Vraja, he once found all the cowherds busily engaged in preparing for a sacrifice to be offered to Indra (q.v.). Seeing this, he dissuaded them from worshiping this god, and directed them to address their prayers and offerings to the mountain *Govardhana*. Indra, however, offended by these proceedings, sent a heavy storm, which inundated the country, and threatened to destroy the cattle. Thereupon, Kr'ishn'a plucked up the mountain Govardhana from its base, and held it up as a large umbrella over the cow-pens, to shelter the herdsmen and their cattle from the storm. For seven days and nights they were thus protected by the elevation of the mountain; and Indra, at last convinced of the irresistible might of Kr'ishn'a, came to Govardhana, and worshiped him, obtaining on this occasion the promise that Kr'ishn'a would befriend the Pân'd'u prince, Arjuna, in his conflict with the Kurus (see MAHÂBHÂRATA). The episode in the life of Kr'ishn'a which now ensued, and is filled up with the pleasures and sports he enjoyed among the Gopîs, or cowherdesses, is that commemorated in the Râsa Yâtrâ, an annual festival celebrated in various parts of India in the month of Kârttika (Oct.–Nov.), and dwelt upon in many poetical works. Of these cowherdesses, later poets especially mention *Râdhâ;* and she is sometimes also represented as the divine or mystical love to which Kr'ishn'a returns at the end of his more worldly amours (see the article JAYADEVA). After some more miraculous deeds, Kr'ishn'a and Balarâma repaired to Mathurâ, where Kansa, in the hope of affecting their death, had invited them to assist at a solemn rite of the lustration of arms, and to engage in a trial of strength with his chief boxers, *Chân'ûra* and *Mushţ'ika*. *Akrûra*, sent by Kansa to convey to them his invitation, had already revealed to them the purpose for which he was despatched; but undaunted by his words, they accomplished their journey, during which they performed several other wonderful deeds, and, arrived at Mathurâ, accepted the challenge of Kansa. The contest ended not only in the death of the two boxers, but in that of Kansa also. Kr'ishn'a now released *Ugrasena*, Kansa's father, from the confinement in which he was kept, and restored him to the throne of Mathurâ. A number of other miraculous feats now followed in the career of Kr'ishn'a. The principal are his conquering *Jarâsandha*, the father-in-law of Kansa, who came to revenge the death of the latter, and *Kâlayavana*, a king of the Yavanas, who also overran Mathurâ with his armies; and his founding the city of Dwârakâ. At the end of these wars, he made a short stay at Vraja, then returned to Dwârakâ, and there married Revatî, by whom he had two sons. But he also carried off violently *Rukmin'i*, the daughter of a king of Vidarbha, who had been betrothed to *S'is'upâla* (q.v.), and had to wage a hot contest with the latter and his allies, before he conquered them. His next war was that with *Naraka*, a demon-king of Prâgjyotisha, who had robbed Aditi of her earrings, and ultimately was put to death by him. He then repaired to Indra's heaven, to restore to Aditi her earrings; but carrying off a wonderful tree from Indra's garden, got into a conflict with this god; ultimately, however, he was allowed by him to take the tree to Dwârakâ. There he married 16,100 maidens, whom he had rescued from Naraka. Other wars followed, in one of which Kr'ishn'a also fought with S'iva, when siding with his enemy Bân'a, who was a son of Bali. The most important, however, of all these contests is the great war between the Kurus and Pân'd'us, in which Kr'ishn'a was the ally of the latter. According to the *Vishn'u-Purân'a*, Kr'ishn'a's earthly career was brought to its close by an event which has nothing in it of the miraculous, and is more consistent with the end of a mortal hero than with that of an incarnate god. He was accidentally shot in the sole by a hunter, who thought that he was aiming at a deer. The hunter, it is true, is called *Jarâ*, which is a word in the feminine gender, and means "old age," or "decay;" but even if a mere allegory, the story of his end "from old age," or an arrow, barely tallies with the character assigned him in the Purân'as, and is therefore sometimes also omitted in the accounts of this Avatâra.—For Balarâma, see also the legend in the article YAMUNÂ.

9. The *Buddha-Avatâra*, or Vishnu's epiphany as Buddha.—It is originally foreign to the cycle of the Avatâras of Vishn'u, and therefore only briefly alluded to in some Purân'as. Where this is done, the intention must have been to effect a compromise between Brahmaism and Buddhism, by trying to represent the latter religion as not irreconcilably antagonistic to the former. See BUDDHISM.

10. The *Kalki-* or *Kalkin-Avatâra*.—It is yet to come, "when the practices taught by the Vedas and the institutes of the law, shall have ceased, and the close of the Kali or present age shall be nigh." Vishn'u will then be born "in the family of *Vishn'uyas'as* (possessing the glory of Vishn'u), an eminent Brahman of Sambhala village, endowed with the eight superhuman faculties. He will then destroy all the barbarians and thieves, and all whose minds are devoted to iniquity."—*Vishn'u-Purân'a*.

Vishn'u's wife is *S'rî*, or *Lakshmî* (q.v.), and his paradise *Vaikunţ'ha*. When repre-

sented, he is of a dark hue, with four hands, in which he holds a conch-shell, blown in battle, the *Pinchajanya;* a disk, the *Sudars'ana,* an emblem of sovereign power; a mace, the *Kaumodakî,* as a symbol of punishment; and either a lotus, as a type of creative power, or a sword, the *Nandaka.* On his breast shines the jewel *Kaustubha.* He is variously represented: sometimes, as *Nârâyan'a* * (see the first Avatâra), when floating on the primeval waters, and resting on *S'esha,* his serpent of infinity—the god Brahman coming out of a lotus that arises from his navel, and Lakshmî being seated at his feet; or riding on *Garud'a,* a being half bird and half man, or seated on a throne, and holding Lakshmî on his lap; or, if he is represented in one of his incarnate forms, as fish, boar, man-lion, etc., he has a human shape, ending in a fish, or a human body with a boar's head, or with a lion's head; or he appears as a dwarf, or (as Paras'urâma) armed with an axe; or (as Balarâma) holding a plow-share. As Kr'ishn'a, he is generally represented in a juvenile form, or as an adult, in a dancing posture, and playing on the flute. As Kalki, he has a sword in his hand, and is kneeling before a winged horse. The leading personages or events connected with these Avatâras are likewise frequently associated with the representation of the god: thus, in the representation of the fourth Avatâra, Hiran'yakas'ipu, as being torn open by the man-lion; or, in that of the sixth, the demon Arjuna, fighting with Paras'urâma; or, in that of the seventh, the ten-headed Râvan'a, battling with Râmachandra; or Hanumat and the monkey chiefs, paying adoration to the latter; while his brothers stand at his sides, and Sitâ is sitting on his lap; or, in the eighth Avatâra, the mountain Govardhana, when uplifted by Kr'ishn'a, and the Gopîs sporting with him. Vishn'u is praised under thousand names, which are enumerated in the *Mahâbhârata,* and have been commented upon by S'ankara, and other authors.—For other myths relating to Vishn'u, the general reader may consult H. H. Wilson's translation of the *Vishn'u-Purân'a,* which has been recently re-edited by Fitz-Edward Hall (five volumes, with index, Lond., 1864–76); the first nine books of *Le Bhâgavata-Purân'a, traduit et publié par Eugène Burnouf,* vols. i.–iii. (Paris, 1840–47); *Harivans'a,* traduit par A. Langlois, vols. i., ii. (Paris, 1834–35); Lassen's *Indische Alterthumskunde,* vol. i. (2d edition, Leipzig, 1866), vols. ii.–iv. (Bonn and Leipzig, 1852–61); and the first and fourth volumes of John Muir's *Original Sanscrit Texts* (Lond. 1858, 63); *Institutes of V.* translated by Jolly in the *Sacred Books of the East* series.

VISHN'U-PURÂN'A. See PURÂN'A.

VISIBLE SPEECH, a system of alphabetic characters, each of which represents the configuration of the mouth which produces the sound. The system is the invention of Mr. Melville Bell—the well-known elocutionist, formerly professor of elocution in University college, London—and was published in 1867, under the title of *Visible Speech* (Trübner). Mr. Bell has since published a short shilling work—*English Visible Speech for the Million* (Trübner), which is quite enough to give a general idea of the system.

Mr. Bell, believing his system to be practically, as well as theoretically, perfect, was anxious to bring it into general use at once, and accordingly made a very generous offer to relinquish all his rights if the expense of casting the new types and publishing the theory of visible speech were defrayed by the government. The proposal was rejected, and Mr. Bell was compelled to publish his system as an ordinary copyright.

Now that the system has been thoroughly tested by the very few who are competent to do so, we are able to give a definite and impartial opinion on its merits, and to say that the absolute perfection that Mr. Bell artributed to it does not exist—that the analysis of sound-formation on which it is based is, in some instances, imperfect or erroneous, and that the symbols might, in many cases, be improved, even where there is no fundamental error of analysis to correct. The chief defects in Mr. Bell's analysis of speech-sounds are: (1) his ignorance of the latest results of German investigations of the mechanism of the throat sounds (whisper, the Arabic gutturals, etc.); (2) his imperfect knowledge of the *synthesis* of sounds, syllabification, word-division, etc.; (3) errors of detail, especially in the consonants, such as his including *f* under the same category as *l* ("divided" consonants), and his analysis of *th.* Other points are still doubtful, and it is certain that, as our knowledge advances, many other difficulties will appear. But it is none the less true that our very knowledge of these defects is due to the vantage-ground on which visible speech has itself placed us. It was an immense advance upon any phonological analysis previously attempted, and opened up once for all the way to arrive at definite results. It was, in short, a *new instrument* placed in the hand of the student of phonetics, and it must, it is clear, for many years to come, continue to be a purely scientific instrument. When finally perfected there can be no doubt that it will come into general use, and finally supersede the present system.

Apart from the question of absolute perfection, we cannot refuse Mr. Bell's analysis our profound admiration as a great work of genius. Unaided by the resources of the German physiologists, he has completely beaten them on their own ground: where they, with all the resources of the laboratory at their command, have painfully collected a few isolated observations, he has erected a splendid edifice. And it is precisely where they utterly break down—namely, in the analysis of the vowels—that his genius shines most

* "The waters are called *nâra,* because they were the production of *nara* (or the supreme spirit); and since they were his first *ayana* (or place of rest, when in the form of the god Brahman), he thence is named *Nârâyan'a* (or resting on the waters)."—*Manu,* i. 10.

brightly. By his discoveries of the distinction of "narrow" and "primary," of the "mixed" vowels, intermediate between the guttural and palatal ones, and of the compound character of the labial vowels, Mr. Bell has been able to select from the enormous number of shades of vowel-sound (for every movement of the tongue produces a new sound), certain definite formations, thirty-six in number, all definitely correlated, which include, with the various intermediate formations, all possible simple vowel sounds.

The system of notation is not less a work of genius than the physiological analysis on which it is based. All the letters are formed by the combination of about thirty radical symbols, most of which are, to a certain extent, pictorial of the action of the organs which produce the sound. Thus a simple circle O represents breath issuing from the *open* throat (aspiration); while the *narrowing* of the glottis which produces vocal murmur is symbolized by I, from which, by modifiers to indicate guttural, palatal, "primary," "wide," etc., all the vowel symbols are formed. Contraction in the mouth is indicated by a C, and the *part* of the mouth in which the contraction takes place is shown by the direction in which the symbol is turned— thus, C denotes contraction in the *back* of the mouth (Scotch and German *ch* in *loch*), Ↄ denotes lip-contraction. Complete stoppage is indicated by drawing a line across the opening, giving a symbol resembling D, which turned this way would represent the sound of *p*, while ᗡ would represent *k*. The symbols for vocality, nasality, etc., are similarly incorporated into the consonant symbols. This will be enough to show the two chief features of the system: (1) its simplicity and perfect consistency; and (2) the correlation of the symbols. Thus, when the student has learned to recognize the symbol for *m* as differing from *b* only in the addition of the sign for emission through the nose, he is at once able to recognize and form for himself the symbols of *ng* and *n*, if he is already acquainted with those of *g* and *d*. Such a system is evidently of the highest value in all philological investigations which involve the study of sound-changes in different languages. It has been found that many phenomena of language, such as "umlaut," which, when formulated in the ordinary Roman type, require a long technical exposition to be made intelligible, explain themselves at once without further comment when transliterated into the visible speech symbols. It is from the use of visible speech by scientific philologists that we hope most, both for the progress of phonetics and general philology, and also for the improvement and ultimate practical application of visible speech itself. A striking example is afforded by Dr. J. A. H. Murray's admirable work on the *Southern Dialects of Scotland*, in which the phonetic portion owes its clearness and exactness mainly to the use of visible speech. It has also been employed by Mr. H. Sweet in his *History of English Sounds*. Mr. A. J. Ellis, lastly, the father of scientific phonology in England, although employing a system of his own, refers constantly to visible speech, to establish the absolute value of his symbols.

The practical applications of the systems to the acquirement of the pronunciation of foreign languages, to telegraphy, to the instruction of the deaf and dumb (for which it is already largely employed in America), and to general elocutionary purposes, are self-evident. It is clear that visible speech has a brilliant future before it, and it is the duty of all interested in the advancement of science and education to do all they can to disseminate a knowledge of it among all classes. See Deaf and Dumb.

VISIGOTHS. See Goths.

VISION, the act of seeing; that faculty of the mind by means of which, through its appropriate material organ, the eye (q.v.), we are percipient of the visible appearances of the external world. Considered in the latter signification, vision includes questions of high importance in relation to some of the most intricate problems of philosophy; as this part of the subject has already been discussed under Perception, the present article will be restricted, as far as possible, to an exposition of the phenomena and laws of vision proper. In opposition to the bulk of mankind, who believe undoubtingly that they actually *see* the externality and solidity of the bodies around them, bishop Berkeley maintained that these properties are not the immediate objects of sight at all, but are simply ideas derived originally from the touch, and erroneously attributed to vision, in consequence of their having been uniformly experienced concurrently with certain "visible signs" (as, for example, color), with which alone the sense of sight is truly conversant; and this theory of vision having since received the adhesion of a great majority of the most able metaphysicians, it will be proper to give an outline of its leading propositions. In doing this, we shall at the same time intersperse such remarks and counter-statements as may appear to be rendered necessary by the progress of opinion and the results of modern experimental inquiry. First, as to the externality, or outness of objects; or, which is the same thing, their distance from the eye. This, Berkeley maintains, cannot of itself and immediately be seen. "For distance being a line directed end-wise to the eye, it projects only one point in the fund of the eye; which point remains invariably the same, whether the distance be longer or shorter." To this position, everywhere assumed by Berkeley to be indisputable, and by his followers admitted to be so, it may be objected, that it contains an unwarranted assumption, viz., that a ray of light is, by its very nature, incompetent to convey an impression indicative of its possessing length or extension; or, to speak more accurately, it assumes that "apparent distance" is not at all affected by a variation in the actual length of the ray intervening

between the eye and the object. Yet it seems obvious, that the facts of vision do not admit of our arguing the matter, as though the line extending from any point of an object to the eye were a mere mathematical abstraction. Every visible point sends forth diverging rays, which form a cone whose base is on the pupil of the eye; and to the eye the place of this visible point is at the intersection, real or virtual, of the rays in question: real, when the radiant point is viewed directly; virtual, when the rays, either by refraction or reflection, are diverted from their original path before reaching the eye. To take a case of refraction: if we notice the distance of a shilling lying at the bottom of an empty vessel, we shall observe, upon filling the latter with water, a manifest diminution in the apparent distance of the shilling, the reason being that the rays, on their emergence from the water, are bent outward, so that the point of their virtual intersection is brought nearer to the eye. In reflection, the place of a visible point is, in like manner, referred to the point of virtual intersection of the cone of rays incident upon the pupil; and by multiplied reflections, the apparent distance of a point actually adjacent to the eye, may be increased to an almost indefinite degree. It is forcibly contended by Berkeley that these facts, involving, as they do, geometrical considerations known only to few, and by none consciously realized in the act of vision, cannot be concerned in our appreciation of distance by the visive faculty. Yet these, and numberless similar experiments, render it evident that both "apparent distance" and "apparent place" are closely dependent upon these geometrical conditions; and, therefore, without assuming that vision is performed by the aid of connate or instinctive geometry (a notion justly condemned by Berkeley), it yet seems highly probable that these lines and angles are the exponents and invariable concomitants of an actual operation of light upon the eye, specific in its character, and by reason of its necessarily varying, *pari passú*, with every change in the distance of the point of intersection of the visual rays, fitted to convey to us an intuitive perception of varying distance.

In the article EYE (q.v.), it has been shown (as, indeed, necessarily follows from optical principles) that the eye does actually undergo specific modifications, depending for their amount on the distance of the object; and there therefore seems an intrinsic probability that these distantial variations in the organ of sight are correlated to those facts of our consciousness which we denominate variations of visible (not tangible) distance; and as, furthermore, it may be demonstrated by optical experiments that the "apparent distance" of a visible point is directly modified, to our perception, by a simple change in the mutual inclination of its diverging rays, it seems an inevitable conclusion, that that agency of light which suggests to our minds differences of distance is competent to suggest distance itself.

Berkeley was quite aware of the necessary connection which subsists between the distance of an object and the divergency of the rays it emits, though it may be doubted whether he adequately weighed the importance of the train of consequences evoked within the eye itself by this variable divergency of incidence; but he affirms that the mind is not by these means helped to a conception of distance except in so far as by experience we have found that increased divergency, carried to the extent of producing "confused vision," is constantly associated with diminished distance. And in proof that this association is merely accidental, Berkeley cites a curious optical experiment, which shows that where the incident rays are caused slightly to converge, instead of their suggesting, as one would be led to expect, that the object is at an enormous distance, the result is altogether different; viz., at first, when the eye is close to the lens, and vision distinct, the object is seen at its true distance, but afterward, as the eye is gradually withdrawn, and vision becomes continually more "confused," the object appears to be enlarged in all its dimensions, and to approach nearer and nearer, until it vanishes in mere confusion from the view. "This phenomenon," he says, "entirely subverts the opinion of those who will have us judge of distance by lines and angles, on which supposition it is altogether inexplicable." To which it may be replied, that the hypothesis being that the mind judges (mediately) by "the various divergency of rays," it cannot fairly be tested by experimenting with rays that are convergent, and that necessarily produce conditions of vision the reverse of those normally prevalent. But, besides, it is now certain that the explanation given by Berkeley is not the true one; for it has been shown, by Prof. Wheatstone, that when the dimensions of a retinal picture are continuously increased (as is the case in the above experiment), the object appears to approach in the most evident manner.

From the doctrine of Berkeley, that the sight is not immediately perceptive of distance, it necessarily follows that the parts of a solid object will not be seen as some of them more remote than others, but as if situated all in one and the same plane. This opinion has accordingly been maintained by more recent writers; yet its unsoundness seems manifest; for, if objects be originally seen, not as solid objects, but as perspective representations on a plane, then this plane must be seen either at no distance (which is absurd), or at the same distance for all objects (for which no reason and no evidence can be assigned); or at distances varying with the distances of the objects; but as the last two and only tenable suppositions assume the visual perception of distance, which is the very principle sought to be invalidated, the theory is thus shown to be futile and self-contradictory. If it be admitted that, by the constitution of the organ of sight in relation to light, we are perceptive of distance at all, it is in the highest degree proba-

ble, judging not only from analogy, but from the proved distantial affections of the eye, that we perceive by the sight degrees of distance; and a perception of the latter implies, it has been shown, a perception of trinal dimensions. Now, although it is strenuously maintained by the adherents of Berkeley that this is not a primitive attribute of vision, it is not denied by any, that in the exercise of our mature sight, we do undoubtedly perceive the outness, the distance, and the trinal extension of visible objects; but, say they, these very qualities, not being modifications of light or colors, are only in appearance directly perceived by the eye; they are, in fact, the product of tactual experience, but by long and invariable association with the phenomena proper to sight, are now instantaneously suggested by them, in a manner so intimate that the two sets of perceptions have become, to our consciousness, indissolubly one. This, in effect, is to affirm that we cannot see an object to be possessed of trinal dimensions, until its occupancy of space is assured to us by the touch; whereas, we venture to maintain, that we see objects to occupy space, and that what we owe to experience is a knowledge that the major part of these visible appearances have, underlying them, that which, on our making a proper disposition of our bodies, will produce in us tactual sensations. We advisedly say the major part, because there are many objects in nature, such, for instance, as wreaths of smoke and vapor, which, though to the sight visibly possessed of trinal dimensions, are totally imperceptible to the touch. And this suggests the remark, that a great diversity of opinion has arisen out of the ambiguous meaning of the word "solidity," by which those who agree with Berkeley always signify, not mere occupancy of space, which, as we have shown, may be associated with a total absence of tangible qualities, but "resistant extension" in three dimensions, which, beyond all doubt, is solely cognizable by the touch. It is, of course, in the former sense alone that we vindicate to the sight an immediate perception of "solidity;" and we do not use the term "occupancy of space" at all in the sense of mechanical exclusion, an idea manifestly derived from touch, but only as affirming the immediately perceived trinal extension of visible objects. It may also be here remarked, that there are many substances of extreme hardness, and therefore in the highest degree perceptible to the touch, which, though set in a strong light, remain quite invisible; as, for example, the sheets of plate-glass used by Prof. Pepper in producing his "ghost-illusions." Indeed, strictly speaking, all *perfectly* transparent substances, and all *perfectly* reflecting (polished) surfaces, are invisible. Again, there are many appearances in nature, into our perception of which there enters no element of tactual experience, even as it respects variety of surface (color, of course, being excluded from this consideration); as, for example, the waves of the sea, spread out in long undulating lines, or breaking in foam upon the shore; and all those objects which, by their minuteness and the delicate diversifications of their shape and outline, elude the cognizance of the touch. These facts are adduced simply to illustrate the complete distinction and independence which subsists between the two sets of sensations, originating, respectively, with the sight and the touch—a point strongly enforced by Berkeley himself, who did not hesitate to affirm, not only that our habit of referring the two sets of sensations to the same objects is the mere effect of our having experienced them together, but that the two sets of ideas thus "intromitted into the mind" belong, in fact, to two classes of objects, numerically distinct —the one outward, distant, and tangible; the other visible, but at no distance, and therefore, in reality, contained within the mind itself. But, as has been well pointed out by Mr. Bailey, this very distinction, taken in conjunction with the undoubted fact, that we do in maturity apprehend by the sight the distance of visible objects, furnishes a strong presumption that those perceptions cannot have belonged originally to the touch. How little tactual sensations are able to modify visual perceptions is exemplified (as Mr. Bailey remarks) by the fact, that "a straight stick, with one end placed in a basin of water, would still appear to the sight to be bent at that end, after a thousand proofs by the touch that it was otherwise." In the same way, the finger immersed in water appears "unnaturally bent, though the experimenter feels it to be otherwise."

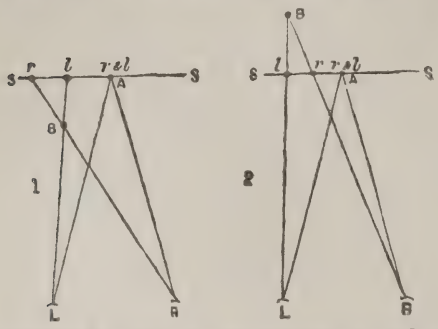
The nature of "visible" or "apparent distance," and how it compares with "real distance," we shall consider when we come to speak of apparent, as contrasted with real magnitude. But we will first inquire what are the optical conditions within the eye itself which determine our perception of the direction of a visible point. Every such point, as we have before remarked, radiates to the eye a cone of diverging rays, whose base is situated in the pupil of the eye; and these rays being refracted in their passage through the eye, are brought to a focus on the retina, thus forming another cone, the base of which is opposed to that of the incident cone, while its apex coincides with the focal point of the refracted rays. If the point of emission be placed directly before the eye, it will be seen in the direction of the common axis of these two cones; or, in other words, in the optic axis; and the central point in which this axis passes through the common basis of the two cones is called the optical center of the eye. Let us suppose, now, another visible point, a little above the first, but at an equal distance from the eye; this, too, will send forth to the eye diverging rays, which will, in like manner, be refracted to a focus upon the retina at a point a little below the preceding; and the line of visible direction will pass from the point of convergence on the retina through the optical center. Now, it is evident that the rays, by means of which we see a visible point, come to the retina from all possible directions within the limits of the cones they

collectively form. How comes it, then, that we perceive the object only in one determinate direction? The explanation usually given (founded on experiments in which a portion of the cone has been excluded without apparent change in the visible direction) is, that, by the constitution of the sense, upon any point in the retina receiving the apex of a cone of rays, we perceive the object in a right line extending from that point of the retina through the optical center; or, according to others, in a right line perpendicular to the surface of the retina at that point. It will, however, be more consistent with the principle that the incidence of light is accompanied by a positive action, related to its direction as well as to its other properties, if we express the law of visible direction by saying, that upon a multitude of rays from all possible directions falling upon a retinal point, the perceived direction is the mean or resultant of them all; which is just as true an account of the phenomena, and amounts, we think, to something more than a verbal distinction. The optical facts we have thus, in brief, indicated, if followed out with respect to all the visible points forming the objects of sight, render it evident that inverted images of the latter are painted upon the retina and the inquiry is prompted, how these can give rise to erect vision. On reflection it will be seen that an explanation of this old and much debated "paradox of vision," is involved in the preceding statement of the law of visible direction, in whichever way it may be expressed; and, as has been shown by previous writers, the difficulty itself has arisen solely from the assumption, contrary to fact, that we *see* the retinal pictures, whereas, considered as images, they are not even the means, but only the concomitants of that operation of light by which we see. Even this important distinction, however, does not convey the whole truth; and we trust it will not be deemed an unnecessary refinement, if we point out that in a strict sense there is no *image* upon the retina, but only a concourse of rays, which, *to the eye of another person*, will undoubtedly give the perception of an image, but cannot be affirmed to exist, as an image, except in relation to this second observer. It is therefore with this reservation that the term retinal images is here made use of. As a consequence of all the lines of visible direction passing through the center of the eye, it follows that as an object recedes from or approaches the eye, its retinal image becomes proportionally less, or greater; and in like manner, the visible object itself varies in magnitude, under certain limitations, to be presently referred to, with every change in its distance. But as "the magnitude of the object which exists without the mind, continues always invariably the same," it is evident, argues Berkeley, that "whenever we speak of the magnitude of anything, we must mean the tangible magnitude," which alone is measurable by "settled stated lengths." The sense in which this is true, clearly illustrates the nature of magnitude and distance, as apprehended by the sight, in contradistinction to what is called real magnitude and real distance, the product of tactual experience. It must not be understood as imputing to the touch of a superiority in mensurative capacity, but as simply meaning, that by the touch we come to know that the external world is endowed with resistant qualities—such as hardness, impenetrability, and incompressibility—qualities which we cannot conceive as modifiable by our bare visual perception of them; and from this experience accrues our conception of the reality and actuality of the magnitude and distance of objects, accompanied by a belief that the variability of magnitude and distance perceived by the sight is an appearance only, and dependent on conditions solely of a subjective kind. If this be a correct view, we are not forced to deny with Berkeley that the objects of sight are numerically the same as those we are cognizant of by the touch.

We must now pass on to the concluding part of the subject—viz., "single vision with two eyes;" in treating of which we shall have recourse, almost exclusively, to the masterly researches of sir Charles Wheatstone, of whose admirable discoveries in this department of knowledge we have already had occasion to speak in the article STEREOSCOPE (q.v.). It will be obvious to those who have read what is there stated, that the question of single vision with two eyes is naturally divisible into two classes—the first including those cases in which the optic axes are parallel, and the retinal images exactly alike; and the second, those in which the optic axes are convergent, and the retinal images dissimilar. Now, to see an object double is to see it in two different places at the same time; and therefore, if it can be shown that by the law of visible direction an impression upon corresponding points of the two retinæ is necessarily referred to the same place, this will account for our single vision of the object at that spot. And on consideration, it will be plain that this is really what happens when the optic axes are parallel, and the images indentical. But it is also evident that this explanation does not apply to the second class of instances; in which the only visible point which depicts itself on corresponding portions of the two retinæ, is that point to which the optic axes are directed. All other points, whether situated before, beyond, or in the plane of the horopter,* are projected upon non-corresponding points of the retinæ; and as these conditions were presumed to be inconsistent with single vision, it was asserted by Aquilonius that objects are seen single only in the plane of the horopter (it has since, with greater consistency, been said, only at the point of intersection of the optic axes); but

* The horopter is a right line drawn through the point of intersection of the optic axes parallel with a line joining the centers of the eyes; a plane drawn through this right line at right angles to the plane of the optic axes, is called the plane of the horopter.

that this is not true is evinced by our common experience that, without movement of the optic axes, we enjoy a certain limited field of distinct vision. Its complete refutation, however, is involved in the theory of stereoscopic vision, which may be thus explained: Let the optic axis of the right eye (R) and of the left eye (L) be converged on the point A; suppose another point B, slightly to the left, and in advance of A; and then through the point B draw lines from L and R respectively intersecting the plane of the horopter in r and l (see fig.). Now, if two diagrams, SS, be prepared (the one representing l and A, and the other r and A), and these be presented to their appropriate eyes in the stereoscope, with the view of each eye limited to its own picture, the points r and l will be seen as a *single* point, situated not on the paper, but in advance of it, in the point of intersection of the lines of visible direction, indicated in the above construction by *Rr* and *Ll*. If the point B be supposed beyond A, and also to the left of it, the lines drawn from L and R to B will intersect the plane of the horopter in l and r (fig. 2); and stereoscopic pictures SS prepared under these converse conditions will exhibit the points l and r as a single point placed behind A at the point of intersection of the lines drawn from L and R respectively. This simple rule involves, as it seems to us, the true principle of the stereoscope; and it is capable of being applied to the most complicated stereoscopic pictures. For, in a stereogram, let l and r stand for identical parts of the left and right pictures respectively, and suppose the pictures superposed; those parts which, read off laterally from left to right, stand in the order *lr* will recede, and those in the order *rl* will protrude (relatively to those parts of the pictures in which r and l absolutely overlie each other), when the pictures are viewed together in the stereoscope. It appears, then, that vision of the third dimension of space is directly obtained by impressions on non-corresponding retinal points; the proof of this being given in the appearance of solidity experienced in the stereoscope, although perfectly plane representations are alone employed; but it would be an error to suppose that this non-correspondence is without a limit; and the question still remains, to what extent the retinal points affected may be non-correspondent, consistently with single binocular vision. Without attempting to propose any definite solution of this difficult question, it may, we think, be considered as highly probable that this limit is determined by the same law which regulates our distinct vision of objects by means of rays inexactly focussed on the retinæ; for, according to Mr. Abbott, "as long as the rays are contained within the area of one sensitive minimum, the sensation will be that corresponding to the vision of a point;" and "a certain amount of dispersion does not interfere with distinct vision." It seems certain that the double perception which is experienced of the further of two objects, when the optic axes are fixed on the nearer, or *vice versâ*, can only arise when the object, thus doubled, is situated within the angle of the optic axes (whether before or beyond their intersection); for under these circumstances only, the sensitive points affected are not simply non-correspondent, but are utterly diverse, being in fact on different sides of the centers of the retina in the two eyes. That the law of projection of the various points composing the relief of a stereoscopic object is correctly stated above, is strongly corroborated by a curious experiment of sir C. Wheatstone's in which solid objects are placed in the stereoscope, instead of pictures. As, for example, two skeleton cubes, so placed, that when the optic axes converge upon them, identical pictures are depicted on the retinæ; in which case, all appearance of relief vanishes, and a perfectly plane perspective representation of a single cube is alone visible; the reason being, that the lines of visible direction for each point intersect each other, neither before or beyond, but *in* the plane of the horopter, where, accordingly, the object is seen as a perspective projection. The same rule holds when the right and left eye pictures are interchanged, for the pictures being supposed, as before, to overlie one another, the parts *lr* become now *rl;* that is, instead of having their point of intersection beyond the plane of the horopter, they have it before that plane; and this, *mutatis mutandis*, being true of all the parts of the pictures, the stereoscopic resultant is the converse of that which would be perceived but for this abnormal arrangement. In these phenomena, named by sir C. Wheatstone the "conversion of relief," and copiously treated of by him in his various papers, the usual relations of distance also are reversed, the nearer parts being seen as further, while the latter are perceived to be of larger dimensions than the former; and, the same principle being applied to the vision of solid objects by means of an instrument called the pseudoscope (q.v.), also invented by sir C. Wheatstone, they are seen as if turned inside out, and under divers other aspects of a most extraordinary character, some account of which will be found in the article just cited. But, as to many of them, it is proper to mention, that the facility of conversion is found to depend, not on the optical conditions, which, of course, remain invariable, but upon mental conditions, as, for instance, previous famil-



larity or otherwise with the converse forms suggested; in short, upon our previous *visual* experience.

We have not yet considered those cases in which the retinal pictures are identical, and the optic axes convergent. In these, the law is, that the object is seen in the plane of the horopter, as is conclusively proved by a beautiful experiment, suggested by sir D. Brewster. If, while looking at a wall-paper, consisting of a small pattern, contin ually repeated at intervals not exceeding 2½ in. from center to center, we cause the eyes to converge to a point in front of the wall, the paper will appear to advance to that point, and will there be plainly visible, in spite of the contradiction of the touch, which, of course, cannot feel the wall where it is seen; while, on the other hand, the eye can perceive no wall in the place where the touch affirms it to exist. The converse of this experiment, although more difficult to perform, is equally curious and instructive. It has also been shown by sir C. Wheatstone, that if an increasing convergence of the eyes be unaccompanied by its usual concomitant, a corresponding enlargement of the retinal pictures, the object is seen as if continuously diminished in all its proportions, albeit the size of the retinal images remains unaltered. This experiment, which, with several others of almost equal interest and importance, may be performed by means of the stereoscope, also establishes that every degree of convergence of the optic axes is associated with the particular adaptation of the eye suited for distinct vision at that distance. This adaptation is, of course, directly dependent upon the divergency, less or greater, of the impinging rays, and this again stands in a necessary relation to the distance, real or virtual, of the point from which they diverge; a branch of the subject to which we have already given sufficient prominence. All observations and experiments concur in showing that a part of the highest importance is played in vision, by the convergence of the optic axes, in particular, in so far as this is conjoined with a difference between the two retinal pictures; and, for this reason, it matters but little that we cannot, within our present limits, enter on a discussion of the evidence obtained from those persons, blind from birth, who have gained their sight by means of a surgical operation; for, in almost every case, only one eye at a time was operated upon, and the information then obtained from the patients, under circumstances of so much difficulty, is admitted on all hands to be of a very dubious and unsatisfactory character.

By mere modification of the light incident upon the eye, the same visible objects may be seen under infinite variations of figure, situation, and magnitude; while, at the same time, their real figure, real situation, and real magnitude, as apprehended by the touch, shall remain unaltered; but these phenomena, artificially induced, argue nothing against the general fact, that under normal circumstances we find, in the very place of the visible objects, those "dynamical qualities" which form the sum-total of our tactual experiences. To Berkeley is due the credit of having first pointed out the original entire disconnection and subsequent intimate blending of the two sets of experience —visive and tactual; but, if the views here proposed be correct, he erred in supposing that our realization of the geometrical proportions and relations of visible objects, is dependent on the suggestions of touch, and not upon the exercise of a primitive and inherent function of sight. To the popular view, the *objects of sight* have a positive and equal existence in absolute darkness, and are simply rendered visible by the light; whereas, they are, in truth, the light itself variously modified. But, in conclusion, while fully admitting that light and its modifications, viz., color in all its varieties, form the sole objects of sight, we venture to maintain that we only know color by our perception of it, as making up, by its superficial distribution, the visible form and shape of the objects of the outer world; and that this our perception of the shape, relative magnitude, and situation of visible objects is immediate, and strictly regulated by the laws of light in relation to the visual organ, irrespective of, and even in opposition to, tactual experience; but, at the same time, we hold that to the touch alone, we owe our ever-present and ineradicable belief, that these visible appearances have underlying them a materiality which we cannot conceive as actually modified concurrently with those changes of form and magnitude, which are perpetually occurring in relation to our faculty of sight; and therefore, in all questions which relate to real size or distance, we necessarily have recourse in thought to those qualities of matter which are apprehensible by the touch.

That an instinctive power of direct visual perception is possessed by the young of the lower species, is not denied by any; whether a like power has been bestowed upon man, we must now leave to the consideration of the philosophic reader.

Mill, in his dissertations and discussions; *Sight and Touch*, by T. K. Abbott; Helmholtz's *Popular Lectures;* art. on vision by Sully, in "Mind," Nos. IX. and X.

VISITATIONS, Heralds', periodical circuits which were in use to be performed by the provincial kings-of-arms in England, in order to take cognizance of the arms, pedigrees, and marriages of the nobility and gentry. A visitation is said to have been held as early as the reign of Henry IV.; but the earliest visitation, in pursuance of a royal commission, was made by Thomas Benolti, Clarencieux, in 1528–29, and comprehended the counties of Worcester, Berks, Oxford, Wilts, Gloucester, and Stafford. From that time, the visitations were repeated at periods varying from 25 to 30 years; never, however, extending to Wales, except on one occasion, in 1581. The latest commission was

dated May 13, 1686, and under it some pedigrees were recorded as late as 1703–4. The cessation of the visitations seems to have arisen from the frequent prohibitions granted by the court of king's bench to stay proceedings in the earl marshal's court, and the abolition of the constable as a permanent officer, in consequence of which the officers-of-arms found it difficult to enforce attendance. The records of the visitations, though not absolutely free from error, contain a mass of historical and genealogical information of great value. They form the principal source of evidence regarding the hereditary right to bear arms in England. The register-books have been scattered among various public and private libraries, including the British museum (which possesses 312 visitation books), the college-of-arms in London, and the Bodleian library. Some of them are no longer extant. A number of the visitations have lately been printed, and others are in the press. A catalogue of the visitations preserved in the British museum was printed by sir N. H. Nicolas in 1825; and an index to the pedigrees and arms in about 250 of the principal MSS. there was published by Mr. Sims in 1849; and an index to all the printed visitations by Mr. George Marshall appeared in 1866.

In Scotland there was no such regular system of visitations. A statute of James VI. (1592, c. 125) empowered Lyon king-of-arms to visit the whole arms used within the realm; and visitations were undoubtedly made in pursuance of this act; but they seem to have been very partial, and no record of them is preserved. Something like a general visitation of Scotland again took place after the restoration, under act 1672, c. 21, the statute instituting the armorial register in the Lyon office, which record was constituted the sole legal evidence of a right to bear arms, and has been continued to the present day.

VIS MAJOR (Lat., "a superior power"), corresponds to the French expression, *force majeure*, and denotes an outward influence, or force, over which man has no control—"the powers that be." The expression has come to have a diplomatic bearing, referring to acts done not in accordance with the inclination of an official, but by reason of the *vis major*.

VISOR, or **Vizor**, otherwise called **Beauvoir** or **Beaver**, the part of the helmet of the middle ages which protected the face. It was perforated to admit light, and movable, so that it could be raised or put down at pleasure. According to the rules established in the later heraldry, the helmet of a knight, when placed over his shield of arms, has the visor up, while that of an esquire has the visor down.

VISTULA, (Lat. *Vistula* or *Visula*, Ger. *Weichsel*, Russ. *Wisla*), an important river of Austria, Poland, and Prussia, rises in Austrian Silesia, near the frontier of Galicia, in a morass in the Jablunka mountains, 15 m. s.e. of Teschen (q.v.), and at the height of 2,000 ft. above sea-level. Formed by three head-waters, the White, the Little, and the Black Vistulas, the Vistula flows n.w. a few miles to the village of Weichsel, where its course is marked by a fall of 180 ft., and thence to the town of Schwarzwasser, where it leaves the mountains. At this point the Vistula turns n.e., and flows in this direction past Cracow, to its confluence with the San, 10 m. below Sandomierz, forming throughout nearly the whole of this part of its course the boundary between Galicia and Poland. From its confluence with the San the river turns to the n., enters Poland, which it traverses in a general n.w. direction, passing Lublin, Warsaw, and Lipno. Leaving Poland it enters the kingdom of Prussia, flowing w.n.w. to its junction with the Bomberger canal; thence n.n.e., past Kulm and Schwetz, to Graudenz, where it turns n. and flows in that direction to its embouchure in the Baltic sea, which it enters by several mouths. About 10 m. below Marienwerder it throws off an arm called the Nogat, which, taking a n.e. direction, and after flowing 32 m., enters the Frisches Haff by about 20 mouths. The main stream continues to flow n. for 115 m., dividing, however, into two branches, one of which flows into the Frisches Haff, the other into the gulf of Dantzic at Weichselmunde, 3 m. below Dantzic. The Vistula receives from the right the Bug, the San, the Dunajec, and the Wieprz; from the left, the Przemsza, Pilza, Brahe, Schwarzwasser, Montan, Ferse and Radune. The Vistula is 714 m. in entire length. It becomes navigable at Cracow for small vessels, and for large vessels at the confluence of the San.

VIS VIVA. See Work.

VISWÂMITRA is one of the most interesting personages in the ancient history of India. According to the Aitarêya Brâhman'a (see Veda), his father was *Gâthin;* and in a remoter degree Viswâmitra derived his pedigree from the king *Purûravas* (q.v.), who was an ancestor of Kus'ika. In the Mahâbhârata, Râmâyan'a, and the Purân'as, his father is called *Gâdhi*, and the origin of the latter likewise traced up to Purûravas; but the distance between the two latter personages is differently filled up in the genealogies given by some of these works. As, according to several accounts, Viswâmitra's sister was *Satyavatî*, who married *Richika*, and bore to him *Jamadagni*, he was the maternal grand-uncle of *Puras'urâma* (see Vishn'u, the sixth Avatâra). He had 100 sons, 50 of whom were, for an offense they committed, degraded by him to become outcasts, and the progenitors of the Andhras, Pun'd'ras, S'abaras, Pulindas, Mût'ibas, and other frontier tribes, which in the Vedas are called Dasyus, or robbers. Viswâmitra is the author of many hymns of the R'igveda (see Veda), especially of its third, Man'dala; but his fame, which pervades all the periods of Sanskrit literature, is chiefly founded on the remarkable fact, that though by birth a Kshattriya, or a man of the military caste—he is also described as a Ra'ja of Canouj—he succeeded in having himself admitted into the

Brâhmanic caste, after a long contest, which, for this end, he had to wage with the R'ishi *Vasisht'ha* (q.v.). That the result of this contest was the elevation of Viswâmitra to the rank of a Brâhman'a, is the account given in the epic poems and the Purân'as; but as the rivalry between Viswâmitra and Vasisht'ha is already alluded to in several passages of the R'igveda hymns, and as at their time the caste distinction of later periods of Hinduism was not yet established, it is probable that the later traditions relating to this contest rested on the circumstance, that *Sudâs*, a king named in the R'igveda, who, as is there stated, employed Vasisht'ha for his house-priest, allowed, for some unknown reason, also Viswâmitra to officiate for him at sacrifices, and that the latter, incurring on this ground the jealousy of Vasisht'ha, had to maintain, probably by force, the prerogative conferred on him by his royal master. In the epic poems and the Purân'as, the rivalry between these two personages is the subject of several legends, which, considering the relative age of the kings referred to in them, would encompass a period far exceeding that of the lifetime of a human being. A kind of consecutive biography of Viswâmitra is given in the first book of the Râmâyan'a, of which it forms one of the most interesting episodes. Its substance is as follows: Once, when roaming over the earth with his armies, Viswâmitra came to the hermitage of Vasisht'ha, and was there received by the saint in the most sumptuous style. Vasisht'ha could afford to entertain the king in this manner, because he possessed a fabulous cow of plenty that yielded him everything he desired. Viswâmitra, becoming aware of the source of Vasisht'ha's wealth, strongly wished to possess the cow, and asked Vasisht'ha to sell her to him. The saint, however, refusing this offer, the king seized her, intending to carry her off by force. But the cow resisted, and ultimately displayed her supernatural powers in producing from different parts of her body numerous peoples, and by their aid destroying the armies of Viswâmitra. The king then had recourse to the magical weapons he possessed, but they were defeated by those of Vasisht'ha; and to the humiliation thus inflicted on him he then gave vent in exclaiming: "Contemptible is the might of a Kshattriya; a Brâhman's might alone is might." And reflecting on what he should do in this emergency, he resolved to practice austerities in order to attain the rank of a Brâhman. In consequence he went to the s. and performed severe penance during a thousand years; when, at the end of this period, the god Brahman appeared, and announced to him that he had become a Râjarshi, or royal R'ishi. But Viswâmitra, not satisfied with this degree of holiness, continued his austerities for another such period. During that time a king, *Tris'anku* of Ayodhyâ (Oudh), of the family of *Ikshwâku*, had conceived the design of performing a sacrifice, that he might boldly ascend to heaven, and solicted for this purpose the assistance of Vasisht'ha, who was the family priest of "all the Ikshwâkus." This saint, however, having declared the scheme of the king impossible, and his sons too, to whom the king likewise addressed himself, having refused compliance with his wishes, he told him that he would resort to another priest, and was, in consequence, cursed by them to become a man of the lowest caste. In this condition he went to Viswâmitra; and the latter showed his power by performing the sacrifice, so much desired by Tris'anku, and accomplishing his object, in spite of the resistance of Vasisht'ha and his sons, and that of the gods themselves. (The *Harivans'a* relates this story with somewhat different detail, but brings it to the same issue. According to the Vishn'u-Purân'a, which alludes to the version mentioned in the last-named work, Tris'anku was the 28th in descent from Ikshwâku; but in the Râmâyan'a, there are only five kings between Ikshwâku and Tris'anku.) This event having caused a serious interruption in the austerities of Viswâmitra, he proceeded to the forest *Pushkara*, in the west, to remain undisturbed. But while he resided there, it so happened that *Ambarîsha*, another king of Ayodhyâ, intending to perform an expiatory sacrifice, and requiring a human victim for this purpose, after a long search, had bought for immolation from the Brâhman *Richîka*, the brother-in-law of Viswâmitra, his son *S'unahs'epha*, and was bringing him home to his capital. On his journey, he halted in the forest Pushkara, and when S'unahs'epha there saw his uncle Viswâmitra, he implored him to come to his rescue. Viswâmitra first directed fifty of his sons to offer themselves up as a ransom for their cousin, and, on their refusing to do so, cursed them to become outcasts; but afterward taught S'unahs'epha two hymns, which, as he said, if sung by him at the sacrifice, would save his life. (In the genealogy of the Râmâyan'a, there are twenty-one kings betwen Tris'anku and Ambarîsha; in that of the Vishn'u-Purân'a, fifteen kings; and in the former, between Ikshwâku and Ambarîsha, twenty-seven; and in the latter, between Ikshwâku and Ambarîsha, the *successor of Tris'anku*, forty-three kings.) The liberation of S'unahs'epha having been effected, and Viswâmitra having continued his penance for another thousand years, the god Brahman conferred on him the dignity of a *R'ishi*. But not yet satisfied with this distinction, he went on practicing still fiercer austerities than those he had practiced before. These the gods succeeded in depriving for a time of their spiritual efficacy, by sending him a heavenly nymph, *Menakâ*, who excited his worldly passions; still, in the end, he attained the rank of a *Maharshi*, or great R'ishi. And, after two other thousand years of still more rigorous penance, which for a time was again interrupted by the allurements of a nymph, Rambhâ, whom the gods had sent for the same purpose as previously Menakâ, the gods, headed by Brahman, came to acknowledge that he had now become a Brahmarshi, or Brâhman'ic R'ishi; and Vasisht'ha himself was compelled to express acquiescence in the result he had achieved.

For other legends relating to this contest between Viswâmitra and Vasisht'ha, see vol. i. of John Muir's *Original Sanskrit Texts* (Lond. 1858); and the article HARIS'CHANDRA. Compare also VISHN'U, the 7th Avatâra.—The name of Viswâmitra is explained in the Markan'd'eya-Purân'a as representing a compound, *vis'wa*, "all," and *amitra*, "no-friend," and meaning "one who is no-friend at all, *scil.*, the three worlds." The Mahâbhârata, however, explains it as *vis'wa*, with its final vowel lengthened, and *mitra*, friend, when it would imply that Viswâmitra was "the friend of all, *scil.*, the gods;" and *Yâska*, the oldest writer, who gives an etymology of this name, likewise renders it "friend of all."

VITA'CEÆ, also called SARMENTACEÆ and AMPELIDEÆ, a natural order of exogenous plants, of which the common vine may be regarded as the type. About 260 species are known, natives of warm and temperate climates, all shrubs, mostly climbing; with simple or compound leaves, with or without stipules, the lower leaves opposite, the upper ones alternate; the flower-stalks racemose, opposite to the leaves, sometimes (as in the vine), by abortion, changing into tendrils.—The only plant of the order of much value, in an economical point of view, is the vine (q.v.), nor are there any fine fruits except its fruit (the grape), and that of species so closely allied to it as to be not improbably mere varieties; but species of the genus *cissus* and of *ampelopsis* (which many unite with *cissus*) are sometimes planted for ornament. *Cissus antarctica* is the KANGAROO VINE of New Holland; and *ampelopsis hederacea*, often called the VIRGINIAN CREEPER, is a frequent ornament of the fronts of houses in Britain, attaching itself to the wall by tendrils terminating in a peculiar kind of sucker, and climbing to a great height.

VITAL STATISTICS are the statistics relating to increase of population, the prevalence of disease, and the duration of human life. In their simplest form, they have to do with the collection, arrangement, and study of the facts preserved in public records, bearing especially upon the birth-rate, health-reports, and death-rate of any locality.

Vital statistics are much more carefully collected and studied in Europe than in our own country. There, each government has a permanent board for the collection of statistics, and, in even the smallest towns, the births and deaths are carefully recorded by the local authorities. In countries like Germany, where every male is subject to military duty, this record is principally maintained for the information of the War office; but it affords a most fruitful and interesting field for the general statistician. In England and Scotland, the annual reports of the registrars-general (see REGISTRATION) form a valuable storehouse of information on the various births, marriages, and deaths, tables of the fatal diseases, classified in combination with ages, are given, and comments upon the salient points of the year's registration accompany the whole. The number of births, marriages, and deaths varies with the state of trade, price of food, and the seasons, and thus furnishes a test of the condition of a nation. In the United States, however, there is no national bureau that has this problem continually before it. The National Board of Health collects much that is interesting and valuable; the boards of health of many of the individual states do the same; and in the great cities, such as New York, Brooklyn, Boston, and Chicago, the vital statistics are properly recorded, but the facts gathered as yet relate to particular localities only, and do not enable one to deduce with accuracy many facts that would be of interest in their relation to the entire country. It will be of interest to take up the three topics with which vital statistics have the most to do, and set forth some of the conclusions that have been drawn from the facts laboriously gathered that relate to them. These three topics are births, longevity, and deaths.

1. BIRTHS.—Births are generally estimated in proportion to every 1000 of the population. Certain facts regarding the birth-rate may be regarded as definitely ascertained. (1) That in most countries, the birth-rate is steadily decreasing. (2) That in urban populations the birth-rate is greater than in the agricultural districts, owing to a higher marriage-rate, the earlier marriage of the women, and the greater mortality of infants which, by shortening the period of suckling, diminishes the intervals of child-bearing. (3) That child-bearing diminishes in proportion to the increase in the social position of the parents. (4) That national prosperity has a direct influence on the birth rate of some countries, but not in all—in England, for instance, but not in France. In England, years of prosperity, in which the necessaries of life are abundant, show regularly an increased birth-rate.

The influence of nationality upon the birth-rate is shown in the following table, which gives the births per 1000 inhabitants in ten countries:

EUROPEAN STATES.	Births to a Marriage.
Italy	5.15
Prussia	4.92
Sweden	4.84
Netherlands	4.83
England	4.63
Belgium	4.48
Spain	4.47
Denmark	4.24
Austria	3.73
France	3.42

The United States offer a good example of the difficulty found in estimating the relative fecundity of the native-born, and immigrant population. The former comprises not only genuine Americans, but also the offspring of foreigners born in the country, and contains an excess of children; while the foreign population contains an excess of adults of reproductive ages. It is evident, therefore, that the comparison of births per thousand of the population would not be fair. Such an erroneous method, in fact, has led to the conclusion that the foreigners are four times as prolific as the native population; whereas, the actual difference is much less marked, though there is, nevertheless, a difference in favor of the foreigners. Mr. Buck has shown that in Massachusetts, for instance, over 57 per cent. of the native women of twenty years of age and upwards, are mothers, and nearly 66 per cent. of the foreigners of the same age.

Statistics show that in all countries of the civilized world more males than females are annually born; that the proportion of males to females is greater in large than in small families, and that it is greater among the earlier born than among the later born children of a family. The following table gives the proportion of male to female births in different countries for a period of ten years:

Country.	Males born to every 1000 Females born.
Italy	1071
Austria	1068
France	1064
Switzerland	1063
German Empire	1062
Holland	1061
Belgium	1059
Scotland	1057
Ireland	1056
England and Wales	1039

It is to be noted, however, that the death-rate among males is more rapid than among females, especially during the first year of life. At the age of thirty-four, the two sexes are about equal in number; after that, the diminution in the proportion of males goes on until, at the age of seventy, the proportion stands at about 900 males to 1000 females. It is generally believed that the explanation of the excess of male births is to be found in the fact that the male parent is usually older than the female parent, the world over. Birth-rates are affected by time, place, and seasons. The birth-rate is usually highest in the first three months of the year. The greater number of births occur between midnight and 6 A.M. From statistics collected by the Philadelphia Board of Health it appears that twins are born about once in every 107 births, and triplets once in every 5600. The percentage of still-births is put on an average of 4.76, or one to every 20.9 births. The direct cause of the increase of population in any country (apart from immigration) is, of course, the excess of births over deaths, and this will plainly depend on the following causes: (1) on the prolificness of marriages; (2) on the proportion born which lives to marry; and (3) on the interval between the mean age of marriage and the mean age of death. All these conditions must be favorable to show the full power of increase in action. They have never yet, on any large scale, at least, been found operating with maximum force. In the United States we find a combination of the first two; but from the "expectation of life" (see Life, Mean Duration of) not being favorable in this country, it follows that the third cause is not in favorable operation. The so-called Malthusian theory regarding the increase of population is well known: "The population is increasing in a geometrical progression; the means of subsistence in an arithmetical progression; and, unless wars, destructive epidemics, marshes, dense towns, close workshops, and other deadly agents carry off the excess of the numbers born—unless the outlets of life and blood be left open—the whole people must be exposed to a slow process of starvation." See Malthus, Thomas Robert. One great objection to this theory has always been found in the fact that the data upon which it is based was collected at a time when great agricultural depression prevailed, and when the production of food was much less than in average years.

2. Longevity.—Vital statistics are largely employed with the question of the probable duration of life. Babbage says, regarding this topic: "Nothing is more uncertain than the duration of life when the maxim is applied to the individual; but there are few things less subject to fluctuation than the duration of life in a multitude of individuals." It is on this principle that annuities and life-insurance policies can be made the subject of exact calculation, the final results being found to vary within extremely narrow limits. The following table gives the probable term of life to be lived by the average person at the ages of 20, 30, 40, 50, 60, and 70:

Age.	"Expectation of Life," according to			
	Mutual Life of New York, Fifteen Years.	"Actuaries," or Seventeen English Companies.	Massachusetts (1855) Tables (Elliott's).	Farr's English, No. 1.
20	42.8	41.5	39.9	39.9
30	36	34.4	34	33.1
40	28.9	27.3	27.9	26.6
50	21.6	20.2	21.3	20
60	14.6	13.8	15	13.6
70	8.6	8.5	9.4	8.5

The influence of different occupations upon longevity has been made the subject of very careful study. An English authority gives the figures which show that the following trades placed according to their expectation, show an inferior expectation: clerks, potters, printers, bricklayers, blacksmiths, mill operatives, plumbers, stone-masons, miners, wool-combers, coopers, hatters, spinners, tailors, dyers, sawyers, millwrights, town and city laborers, and shoemakers. The following trades show a superior expectation: wheelwrights, butchers, bakers, weavers, domestic servants, carpenters, and rural laborers. Of the professions, statistics show that clergymen live to the greatest ages, lawyers die considerably younger, while physicians are at a disadvantage compared with lawyers. Taking 1000 to represent the majority of all males, the mortality among clergymen will be represented by 556; of lawyers, 842, of teachers, 719, and of physicians, 1122. Matrimony exercises a favorable effect upon the longevity of the individual. The following table compiled by Dr. Bertillon shows that the death-rates of married adults are considerably lower than those of the unmarried, while the death-rates for widowers and widows are the highest of all:

DEATH-RATE PER 1000 LIVING OF MARRIED AND UNMARRIED.

Ages.	Males.			Females.		
	Single.	Married.	Widowers.	Single.	Married.	Widows.
20–25	12.88	8.92	49.60	8.32	9.92	12.31
25–30	10.17	6.24	21.84	9.02	8.98	23.62
30–35	11.51	6.82	19.17	9.87	9.36	16.90
35–40	13.15	7.52	17.50	10.87	9.29	15.03
40–45	16.62	9.55	18.89	13.28	10.14	12.73
45–50	19.60	11.47	22.20	15.71	13.69	13.30
50–55	25.80	15.61	26.80	20.97	14.11	15.20
55–60	32.10	21.50	34.17	26.90	19.29	24.47
60–65	45.92	32.60	47.50	40.52	30.75	37.07
65–70	58.50	44.80	62.97	58.30	45.30	53.50

Longevity is the greatest in those whose lives are regulated by a strictly normal physiological standard. This consists in the perfect balance of all the organs and their harmonious working. Dr. Nathan Allen aptly compares the body to a complicated machine, so thoroughly and perfectly made that the friction comes equally on every part according to the design of its construction. A change at any one point destroys the balance and thus becomes the entering wedge of disease. Hence the true standard of health is when every organ is perfect in structure and function. Hence we find that the very aged are remarkable for the evenness of the mental, moral, and social elements of their character. The law of longevity is practically, too, the law of increase. A predominance of the nerve tissue tends to lessen the birth-rate, and hence to extinguish gradually the race. This is illustrated in the case of the nobility of Europe and of the native Americans of New England.

Students of vital statistics are skeptical regarding the cases of extreme longevity that form a part of the literature of the subject. Such statements as those recorded in history, to the effect that Attila the Hun lived to the age of 124, that Piastus, king of Poland (A.D. 824), lived to the age of 120, and other similar assertions, are generally rejected. There are many well-authenticated instances of centenarians who have lived within the last four years. The best-known example is M. Chevreul, the distinguished French chemist, who died April 9th, 1889, at the age of 102. In 1886, Mr. Frederick Nash, of Westport, Conn., published a list of twenty-three centenarians then living in Connecticut, the record of whose ages seemed to be beyond question.

The average longevity of the human race is steadily increasing in England, France, and the United States. This is due to a much greater attention to the laws of health, to better food, to the more perfect, modern system of sanitation, and to the great advance in the science of preventive medicine. See Longevity.

3. Deaths.—The following table, compiled by the officials of the Marine Hospital in Washington in May, 1891, shows the death-rate in the principal cities of the United States for the preceding year:

	DEATH-RATE PER 1000.		DEATH-RATE PER 1000.
Auburn, N. Y.	22.1	Newport, R. I.	17.1
Baltimore, Md.	23.3	Newton, Mass.	14.8
Binghamton, N. Y.	16.0	New York, N. Y.	26.6
Boston, Mass.	22.9	Pensacola, Fla.	10.8
Brooklyn, N. Y.	24.3	Philadelphia, Penn.	20.7
Charleston, S. C.	32.4	Pittsburg, Penn.	21 3
Chicago, Ill.	19.6	Portland, Me.	19.9
Cincinnati, Ohio	22.3	Providence, R. I.	19.2
Cleveland, Ohio.	19.2	Richmond, Va.	28.3
Denver, Col.	26.9	Rochester, N Y.	15.8
Galveston, Texas	20.4	St. Louis, Mo.	18.3
Indianapolis, Ind.	16.2	San Diego, Cal.	10.6
Louisville, Ky.	21.9	San Francisco, Cal.	22.8
Nashville, Tenn.	18.8	Washington, D. C.	23.7
Newark, N. J.	25.1	Yonkers, N. Y.	16.8
New Orleans, La.	29.2		

The following table gives the average death-rate in the principal foreign cities:

	DEATH-RATE PER 1000.		DEATH-RATE PER 1000.
Alexandria, Egypt	36.52	Liege, Belgium	23.22
Amsterdam, Holland	24.48	Liverpool, England	26.94
Antwerp, Belgium	26.03	London, England	23.62
Aschersleben, Germany	22.31	Madras, India	34.36
Basel, Switzerland	26.07	Manchester, England	26.80
Belfast, Ireland	30.66	Manchester Parish, Jamaica	13.68
Belgrade, Servia	38.22	Marseilles, France	32.32
Berlin, Germany	27.80	Melbourne and suburbs, Victoria	19.23
Bern, Switzerland	31.42	Milan, Italy	29.51
Bernburg, Germany	23.16	Montreal, Canada	27.44
Birmingham, England	22.12	Naples, Italy	29.28
Bombay, India	34.87	Naumburg, Germany	22.23
Bremen, Germany	22.44	Nottingham, England	22.54
Bruges, Belgium	25.53	Odessa, Russia	37.91
Brussels, Belgium	24.38	Paris, France	25.69
Buda-Pesth, Hungary	37.51	Portland Parish, Jamaica	20.27
Calcutta, India	30.37	Portsmouth, England	16.67
Christiana, Norway	17.40	Prague, Bohemia	29.26
Clarendon Parish, Jamaica	20.78	Quedlinburg, Germany	25.06
Coburg, Germany	18.89	Rome, Italy	22.80
Cologne, Germany	26.36	Rotterdam, Holland	27.02
Copenhagen, Denmark	25.79	St. Andrew's Parish, Jamaica	27.13
Dresden, Germany	24.02	St. Ann's Parish, Jamaica	19.88
Dublin, Ireland	35.70	St. Catherine's Parish, Jamaica	23.92
Edinburgh, Scotland	19.59	St. Elizabeth's Parish, Jamaica	21.28
Eisenach, Germany	22.70	St. Mary's Parish, Jamaica	21.76
Frankfort-on-the-Main, Germany	21.55	St. Petersburg, Russia	38.81
Glasgow, Scotland	23.07	St. Thomas' Parish, Jamaica	22.87
Gottenburg, Germany	26.54	Sheffield, England	21.21
Hamburg (including Territory), Germany	26.53	Stockholm, Sweden	22.52
Hanover, Germany	20.07	Sydney, New South Wales	21.06
Havana, Cuba	46.32	The Hague, Holland	24.82
Havre, France	34.19	Trieste, Austria	35.63
Kingston Parish, Jamaica	37.05	Vienna, Austria	28.57
Kingston-upon-Hull, England	22.10	Warsaw, Russian Poland	25.73
Leeds, England	22.49	Wiemar, Germany	16.57
Leicester, England	21.54	Wissenfels, Germany	26.86
Leipsic, Germany	23.46		

In the census year of 1880, the proportion of deaths to the population in the United States (rate per 1000) was 15.09, composed as follows: Alabama, 14.20; Arizona, 7.20; Arkansas, 18.46; California, 13.33; Colorado, 13.11; Connecticut, 14.74; Dakota, 9.65; Delaware, 15.09; District of Columbia, 23.60; Florida, 11.72; Georgia, 13.97; Idaho, 9.90; Illinois, 14.63; Indiana, 15.78; Iowa, 11.93; Kansas, 15.22; Kentucky, 14.39; Louisiana, 15.44; Maine, 14.67; Maryland, 18.10; Massachusetts, 18.59; Michigan, 12.06; Minnesota, 11.57; Mississippi, 12.89; Missouri, 16.89; Montana, 8.58; Nebraska, 13.11; Nevada, 11.69; New Hampshire, 16.09; New Jersey, 16.33; New Mexico, 20.37; New York, 17.38; North Carolina, 15.39; Ohio, 13.32; Oregon, 10.67; Pennsylvania, 14.92; Rhode Island, 17.00; South Carolina, 15.80; Tennessee, 16.80; Texas, 15.54; Utah, 16.77; Vermont, 15.12; Virginia, 16.32; Washington, 10.05; West Virginia, 11.99; Wisconsin, 12.17; Wyoming, 9.09. Of this proportion 1.82 died from consumption; rate per 1000 of total deaths from that disease, 120.95; total number of deaths from consumption, 1880, 91,551.

For fuller information on the subject of Vital Statistics, the reader is referred to the following works: Farr, *Vital Statistics*, ed. by N. A. Humphreys; Buck, *Hygiene and Public Health* (1878); Humphreys, *The Decline in the Death Rate* (1883); Parks, *Some Aspects of Mortality Statistics* (1888); Ransome, *The Vital Statistics of Towns* (1888); Newsholme, *Vital Statistics* (1891). See Sanitary Science.

VITASCOPE. See ZOETROPE.

VITE, OR VITA, TIMOTEO, called also Timoteo della Vite di Urbino, an Italian painter and a relative of Raphael, was born at Urbino in 1470. His art studies were prosecuted at Bologna under Francesco Francia, but in 1496 he went back to Urbino, then removed to Rome to study in the academy his distinguished relative had opened in the Vatican. Later, he returned to Urbino, where he died in 1524. He aided Raphael in his frescos of the Sibyls, and acquired some of the former's grace of composition and manner of coloring. He painted Raphael's portrait, and a number of works of great merit, among them a "Conception" for the Osservanti at Urbino, and a "Noli Me Tangere," for the church of St. Angelo at Cagli. It is believed that Pietro della Vite, an imitator of Timoteo and known to be also related to Raphael, was a brother.

VITEBSK, a government in the n. of West Russia, bounded on the n.w. by Courland and Livonia, and on the n.e. by the government of Pskov. Area, 17,440 sq. m.; pop. '94, 1,426,901. The surface is, as a rule, hilly, though wooded plains, marshes, and lakes abound. The Dwina flows for 466 miles in this government; and by means of this river and its affluents, large quantities of timber are floated down to the port of Riga. The soil is fairly fertile, and flax is successfully grown in large quantities; and this material, together with timber, constitutes the chief articles of export. Shipbuilding is carried on, on the Dwina; the lake-fisheries are profitable; and tanning is the most important branch of industry.

VITEBSK, a city of West Russia, capital of the government of the same name, on both banks of the Western Dwina, 345 m. s. of St. Petersburg. It covers a very large area, and contains many monasteries, churches, and synagogues. Manufactures are not extensive; and the trade—the chief articles of which are corn, flax, hemp, tobacco-leaves, sugar, and timber—is carried on by Jews, who form the larger section of the population. Vitebsk is connected by railway with Dünaburg and Smolensk. Pop. '97, 66,143.

VITELLI, VITEL, OR WITTEL, GASPARD VAN, called also Gaspard degli Occhiali, 1650–1736, painter, was born in Utrecht. He studied under Mathieu Withors, but when quite young went to Italy, where he passed the rest of his life, part of the time at Naples, whither he was called by the viceroy, who became a devoted patron. Vitelli was a most faithful delineator, and an industrious worker, in spite of the loss of one eye. His perspective was fine and his coloring brilliant. Among his works were miniatures in the style of Canaletto, and many architectural and landscape paintings; among them, "View of the Castle of St. Angelo," now in Florence, and "View of St. Peter's at Rome," in a gallery in Vienna.

VITELLIN. This name was, until recently, given by chemists to a supposed protein body occurring in the yelk of egg. It has been discovered by Lehman that this substance is merely an admixture of casein and albumen.

VITELLIUS, AULUS, Roman emperor, son of Lucius Vitellius the prince of the sycophants who surrounded Caligula, but who, according to Tacitus, "in his provincial administration exhibited the virtues of a former age," was born Sept. 24, 15 A.D., and through his father's influence at court became consul, 48 A.D., and afterward proconsul of Africa, where his administration gave great satisfaction. He had been a companion of Tiberius at Capreæ, and was equally a favorite with Caligula, Claudius, Nero, and Galba, the last of whom appointed him commander of the legions in Lower Germany, thinking his intense devotion to gastronomic pleasures would effectually prevent his becoming a rival. However, Vitellius had not been a month in his new post, till he had completely gained the affections of his soldiers by extreme familiarity and liberality (strongly contrasting with Galba's parsimony); and on Jan. 3, 69, they took him from his tent, and proclaimed him emperor. This decision was adopted by the rest of the troops in Gaul; and two armies, under Valens and Cæcina, immediately set out to secure Rome, Vitellius following leisurely. A notice of his contest with Otho in Northern Italy will be found under OTHO. The adherents of his predecessor were leniently treated, with the exception of the centurions of Otho's army, who were put to death, an act which greatly offended his own supporters. Vitellius's journey to Rome was a curious specimen of a triumphant advance, the nominal conqueror being invariably muddled with liquor, and the soldiers of his army straggling about, committing excesses of all sorts with perfect impunity. At last he reached Rome, and without loss of time proceeded, by right of his office as Pontifex Maximus, to deify Nero. The administration was mostly in the hands of the freedman Asiaticus, though P. Sabinus (brother of Vespasian), and the two generals who had gained for him the imperial dignity, were high in authority; and the government was marked by great moderation, for Vitellius was too far sunk in the vilest debauchery to be capable of tyranny. But he was not long allowed to disgust the respectable part of the citizens of Rome; for the legions of Pannonia and Illyricum, having proclaimed Vespasian emperor, advanced into Italy under Antonius Primus. They were opposed by the Vitellian troops, commanded by Cæcina, but through the treachery of the latter general, gained a decisive victory near Bedriacum, and another, on the following evening, over another Vitellian army which had marched to the support of the first. Vitellius, at this critical period of his fortunes.

nothing abated his swinish indulgences; but his brother, Lucius, in the south, displayed more energy, and defeated Vespasian's partisans in several battles. Meantime, the soldiers, enraged at the treachery of P. Sabinus, and his allies among the senators and knights, stormed the Capitol, and slew Sabinus. From this time, Rome was a scene of unintermitting violence and bloodshed till the troops of Primus entered the city. Vitellius was found wandering about his palace in a state of stupid terror, and after being ignominiously exposed in the streets, was killed by repeated blows, his head carried about Rome, and his body thrown into the Tiber, in Dec. 69 A.D.—For a complete sketch of his private life, see Tacitus's *Historia*, ii., iii., and Dion Cassius, 65; see also Suetonius, *Vit. Duodec. Cæsarum.*

VITELLIUS, Erasmus, was born at Cracow, Poland, about 1470, and died in 1522. He was of humble or obscure origin, and was educated at the University of Cracow by a family named de Vitellio, whose name he assumed. He became doctor in 1491, and in 1504 was made bishop of Plock. He was employed in various diplomatic services, and in 1518 was sent to the Diet of Augsburg by Sigismund the Great (q.v.) to ask for help against the Turks.

VITELLIUS, Lucius, father of the Emperor Aulus Vitellius, was consul in 34 A.D., and later was appointed governor of Syria. By his arts he induced Artabanus, King of the Parthians, to conclude a peace, and to make obeisance to the signa of the Roman legions, but incurred the jealousy of Caligula, who sent for Vitellius in order to put him to death. The latter, by the grossest flattery and humiliation, saved himself, and by similar means obtained favor with Claudius and Messalina, and was promoted in office, being twice consul under Claudius. After the execution of Messalina, Vitellius upheld Claudius in his desires to marry his own niece, Aggripina. In spite of his bad repute at Rome, Vitellius, who died about the year 52, was honored by the senate with a public funeral, and a statue, erected in front of the Rostra. His son Lucius was consul in 48 A.D.

VITELLUS O'VI, or the *yelk* of the egg of the domestic fowl, is employed in pharmacy for the purpose of administering substances insoluble in water (the oils and resins, for example) in the form of emulsions. The *white* is employed as an antidote, in cases of poisoning by corrosive sublimate or with salts of copper. As a dietetic article in the sick-room, eggs, either lightly boiled or poached, or as ingredients of puddings, are invaluable; the stomach, after an acute disease, being often able to digest an egg, when any more solid article of animal food would set up gastric irritation.

The article Egg, Chemistry of, requires a few supplementary remarks. The albumen, occurring in the *white*, is for the most part in combination with soda; in addition to this principal ingredient, the white contains fats (chiefly margarin), grape-sugar (averaging 5 per cent of the dried residue), and soluble salts, in which the chlorides preponderate, with a little silica (for the formation of feathers) and fluorine. The yelk consists of casein (forming 14 per cent), albumen (about 3 per cent), fats, some of which contain phosphorus (about 30 per cent), a little grape-sugar, and mineral constituents (about 1.5 per cent), in which there is a great preponderance of potassium compounds and phosphates. Of the pigments of the yelk we only know that there is both a yellow and red pigment, and that one at least of them contains iron. It is difficult to conceive a more concentrated form of nourishment than a food thus composed of casein, albumen, fat, sugar, potassium salts, phosphates, and iron; and its resemblance in composition to milk is very remarkable.

The shell of the egg consists almost solely of carbonate of lime (about 97 per cent), with a little phosphate of lime, and traces of magnesia and organic matter. The variety of color in the eggs of different birds is supposed to be due to certain modifications of bile-pigment with which they come in contact in the cloaca.

VITERBO, a city in central Italy, in the province of Rome, stands amid gardens and vineyards, at the foot of Monte Cimino, 54 m. n.n.w. of Rome by railway. Its well-built streets are paved with marble, and there are numerous elegant fountains. Its Gothic cathedral contains the tombs of several popes, and is memorable as the scene where Guy de Montfort assassinated prince Henry, nephew of Henry III. of England. Pop. 18,000.

VITET, Ludovic or Louis, a French author and statesman, was born at Paris in Oct., 1802, and studied at the normal school in that city. His first book, *Les Barricades* (1826; 4th ed., 1850), was published anonymously, but had an important effect upon modern dramatic literature; this, together with *Les États de Blois* (1827), and *La Mort de Henri III.* (1829), were combined in one work entitled *La Ligue* (1844). In 1830 he obtained from Guizot the position of inspector of historical monuments, an office created especially for him; in 1834, became secretary-general of commerce, and in 1836, entered the council of state. From 1834 to 1848 he represented Seine-Inférieure in the Chamber of Deputies, supporting conservative policies; was returned in 1871, and was several times vice-president. He was admitted to the French Academy in 1845. He died at Paris in June, 1873. His works in art, archæology, and philosophy are numerous.

VIT'EX, a genus of trees or shrubs of the natural order *verbenaceæ*, the fruit a drupe, with a 4-celled stone. *V. agnus castus*, the Chaste Tree, a native of the countries around the Mediterranean, is downy, with digitate leaves, white on the back, and has an

acrid fruit, the seeds of which are used in Smyrna as an external application in cases of colic. It derives its name from the practice of Grecian matrons to strew their couches with its leaves, especially during the sacred rites of Ceres, in order to banish impure thoughts; for which purpose a syrup, made of its fruit, was also, and perhaps still is, used in convents in the s. of Europe, although, in reality, it possesses stimulating properties.— *V. negundo*, an Indian species, has aromatic leaves, which are bruised and applied to the temples for relief of headache.— *V. trifolia* is another Indian species, whose leaves are a powerful discutient.

VITICULTURE. See VINE.

VITILI'GO was the name given by Celsus to some kind of cutaneous eruption which cannot be clearly identified. The term has, in recent times, been used by different writers in different senses, but is now most commonly employed to designate cutaneous patches characterized by loss of pigment.

VITIOUS INTROMISSION, in the law of Scotland, means the unwarrantable interference and management of the movable estate of a deceased person.

VITO'RIA, a pleasant, gay, and thriving inland t. in the. n. of Spain, capital of the province of Alava, stands on a gentle elevation, 70 m. w. of Pamplona. The old town, the Villa Suso, consists of dark and tortuous streets; the new town is regularly laid out. There are several charming *alamedas*, or public walks, especially La Florida and El Prado. The plaza Nueva, a square of 220 ft., was built in 1791, and under its arcades is the favorite promenade in winter. Brass and iron wares, leather goods, candles, and linen goods are manufactured, and a brisk general trade is carried on with towns further inland. The plain surrounding the town is extensive and fruitful. The climate is temperate and healthy. Pop. '87, 27,660.

Vitoria will be ever memorable for the decisive and important victory which Wellington gained here over the French under Joseph Bonaparte and Jourdan, June 21, 1813. The numbers in this encounter were nearly equal. The French lost 6000 killed and wounded, 150 cannon, together with baggage, eagles, and an amount of booty in pictures, etc., which amounted to $5,000,000. The direct result of the battle of Vitoria was, that the French had to retire from Spain. About this engagement, Southey says the French "were beaten before the town, in the town, through the town, out of the town, behind the town, and all about the town." The loss of the British, Portuguese, and Spaniards was 4900 men.

VITRÉ, an ancient t. of Brittany, France, in the department of Ille-et-Vilaine, on the left bank of the Vilaine, 24 m. e. of Rennes by railway. It is a curious specimen of the old towns of the middle ages, and is still partly surrounded with Gothic ramparts flanked with towers. Four m. s. is the château des Rochers, the celebrated residence of Mme. de Sévigné. Manufactures of cloth and hats are carried on. Pop. (commune) 10,607.

VITRIFIED FORTS, the name given to certain remarkable stone inclosures bearing traces of the action of fire, about fifty of which exist in various parts of Scotland. They are generally situated on a small hill, overlooking a considerable valley, and consist of a wall, which may have originally been about 12 ft. in height, inclosing a level area on the summit of the hill. The most remarkable feature of these structures is, that the wall is always more or less consolidated by the action of fire—in some cases only to the extent of giving a glassy coating to its inner side, while in other instances the vitrification has been more complete, the ruins assuming the character of vast masses of coarse glass. Structures of this kind are to be found at Noath and Dunnideer, in Aberdeenshire; Craig Phadrick, Tordun, and Glenever, in Inverness-shire; Knockfarril, in Rossshire; Creich, in Sutherlandshire; Dunskeig, in Argyleshire; Finhaven, in Forfarshire; and elsewhere, but principally in the northern counties. They were first noticed by Mr. John Williams, in his *Account of some Remarkable Ancient Ruins lately discovered in the Highlands and Northern Parts of Scotland*, published in 1777. Mr. Williams's observations led him to conclude that they were artificial structures intentionally vitrified by a partial melting of their materials. Mr. Williams's views were combated by other writers, who contended that the supposed forts were of volcanic origin, a supposition quite irreconcilable with their obviously artificial character. In 1828 the subject engaged the attention of the society of antiquaries of Scotland, a series of careful observations being made by Dr. Samuel Hibbert, one of the secretaries of that body; and the conclusion arrived at was, that while the structures were artificial, the vitrification was an accidental effect, which might have arisen from such causes as the frequent kindling of beacon fires as signals of war and invasion, or of bonfires forming a part of festive or religious rejoicings. The alkali produced from the accumulation of the ashes of continually blazing wood-fires would be a powerful aid to the fusion of stone. The view originally taken by Mr. Williams has since been supported by Dr. John M'Culloch, who argues that the character of the works shows them to have been designed for defensive military posts, and observes, that in some cases where the most accessible materials for a stone-fort are incapable of vitrification, stones more capable of being vitrified have been brought from a distance. Dr. Petrie has noted one vitrified fort in the county of Cavan, and four in the county of Londonderry, and he conjectures that they belonged to the Irish Picts. A single instance, that of the "camp of Péran" in Brittany, occurs in France. In this case, only the central portion, or core, of the wall is vitrified, and in it

a Roman roofing tile was found by M. Lukis firmly attached to the melted stone. A number of the hill-forts of Bohemia have also been found to be constructed with a core of vitrified stones occupying the center of the walls. Dr. Fodisch attributes them to the bronze age and to a Celtic race. More detailed descriptions of these Irish, Breton, and Bohemian examples, however, are necessary to enable us to pronounce definitely as to their identity with those of Scotland. But there seems to be little doubt that the vitrification in them all was the work of design, though produced, it may be, by different methods, and with structural intentions not quite the same.—See *Archæologia Scotica*, vol. iv.; M'Culloch's *Highlands and Western Islands of Scotland;* Burton's *History of Scotland*, chap. 3; *Proceedings Soc. Antiq. Scot.*, vol. viii. p. 145.

VITRINGA, Campegius, an eminent Dutch divine and commentator, was b. at Leuwarden in Friesland, May 16, 1659. He studied at Franecker and Leyden, at which latter place he was created D.D. in his 20th year. In 1681 he was appointed professor of oriental languages; and two years later, received the chair of theology in the university of Franecker, where he died, Mar. 21, 1722. Vitringa is regarded as one of the most learned and laborious divines of his age, and has left many excellent and erudite works, chiefly commentaries on portions of the Scriptures, nearly all of which are in Latin. Among others may be mentioned, *Commentarius in Jesaiam; Anacrisis Apocalypseos Johannis Apostoli; Commentarius in Jeremiam; Commentarius in Zecharaiam; Vetus Synagoga; Dissertationes Sacræ; Typus Theologicæ Propheticæ*, etc.

VITRIOL (derived from the Latin *vitrum*, glass) is a term which the early chemists applied to glass-like salts, distinguishing them by their colors into blue vitriol, green vitriol, and white vitriol. *Blue vitriol* is still the popular name for sulphate of copper, which may be obtained on a large scale in various ways; by roasting copper sulphide (CuS), and extracting with water; by crystallizing the water of copper mines; by moistening copper with sulphuric acid and exposing it to air or to heat; by the action of hot, strong sulphuric acid on copper. Practically, it is seldom made directly from copper but from the sulphide, copper "matt," and the solution obtained in parting silver. It occurs in large, blue, triclinic prisms, with the formula, $CuSO_4,5H_2O$. These require, at ordinary temperatures, nearly three times their weight of water for solution (2.71), but dissolve in .55 parts of boiling water; the solution is blue, astringent in taste, acid in reaction. The crystals lose a little water spontaneously; when heated to 100°C. (212°F.) they lose $4H_2O$, and at about 200°C. (392°F.) the remainder; in this condition the salt is used as a drying agent because of its readiness to recombine with water. Copper sulphate is largely employed in batteries, in electro-plating, in the manufacture of pigments, especially blue and green, and in the preservation of wood. It has some application in medicine. It is stimulating, irritant, astringent, and even escharotic. Its internal use is almost wholly to stimulate the gastro-intestinal mucous membrane. In doses of 5 grains it acts as an emetic, but sulphate of zinc is better. Externally it is applied to warts, ulcers, granulations, and bleeding surfaces.

Green vitriol is the popular name for sulphate of iron. Its characters, the method of obtaining it, and its therapeutic uses, are sufficiently noticed in the article Iron.

White vitriol will be described in the article Zinc.

Oil of vitriol is the old name given to commercial sulphuric acid, in consequence of its oily appearance, and of its being formerly obtained from green vitriol.

Elixir of vitriol is the old name for the aromatic sulphuric acid of the pharmacopœia. It is a mixture of three ounces of sulphuric acid and two pints of rectified spirit, in which powdered cinnamon and ginger have been digested. Its uses in doses of from ten to thirty minims, in a wine-glassful of water, are much the same as those of dilute sulphuric acid, but it is more agreeable to the taste, and sits more lightly on the stomach.

Vitriolated soda is an old name for the sulphate of sodium ($Na_2SO_4,10H_2O$), as it may be made by the action of oil of vitriol on various soda salts.

Vitriolated tartar is sulphate of potassium (K_2SO_4).

VI'TRO DI TRI'NA, the name given to a beautiful kind of glass which was made by the Venetians in the 15th century. Its distinguishing character is a series of wave-like marks in opaque colors, but usually white, arranged pretty regularly in the substance of transparent glass.

VITRU'VIAN SCROLL, a continuous scroll-work forming a kind of cresting used in classical architecture.

VITRU'VIUS, the name of two Roman architects, the most celebrated of whom is Marcus Vitruvius Pollio, about whom we have no direct information further than the mention of his name by Pliny and Frontinus, though, from the references to himself in his own work, we can gather that in all probability he was born about 76 or 80 B.C. He received a liberal education, pursued specially those studies which were calculated to fit him for the profession of an engineer and architect, and was engaged in the African war (46 B.C.) as superintendent of military engines. He does not seem to have become very popular as an architect, and never succeeded in acquiring wealth, though the constant patronage which the emperor (Augustus) was induced by his sister (probably *Octavia Minor*) to extend to him, insured him comfortable subsistence during his

life. The only public work he executed was a basilica at Fanum. Vitruvius in his book, *De Architectura*, enters at some length into the reasons which induced him to write it, the chief of them being, the care bestowed by his patron (after settled peace had been secured to the empire) on buildings public and private, his intention to erect numerous edifices, and the danger that, owing to the depraved architectural taste of the time, the beauty and correctness of the pure Grecian models would be neglected. The *De Architectura* is arranged in ten books; the *first* of which contains a dedication to the emperor, a general view of architectural science, hints as to the proper subjects of study for young aspirants, and directions for building cities; the *second* treats of the early history of architecture, and of the materials employed at various times, and contains a sketch of the physical theories of various philosophers; the *third* and *fourth* treat of the erection of temples, and in connection with this, of the four orders of architecture, Ionic, Corinthian, Doric, and Tuscan; the *fifth* treats of public buildings; the *sixth*, of private houses in town or country; the *seventh*, of the finishing and decoration of private buildings; the *eighth* of water, the mode of discovering it, whence it may be obtained, and the modes of conveying it in large quantities to a distance; the *ninth*, of the principles of gnomonics, the rules for dialling, and other subjects physical and astronomical; and the *tenth*, of machines used in building and in military warfare, of the mechanical powers, of mills, engines for raising water, odometers, etc. To each book there is a preface, more or less connected with the main subject of the book, and it is in these prefatory remarks that we discover what we know of Vitruvius's personal history. There have been many editions of Vitruvius; the first was published along with Frontinus's *De Aquaeductibus* at Rome about 1486, and afterward at Florence (1496) and Venice (1497). rude woodcuts were introduced into various subsequent editions; that of Bode (Berl., 1800) has a volume of plates; but the best edition is that of Rose and Müller-Strübing (Leipsic, 1867). There is an English translation by Gwilt (last ed. London, 1874).

VITTO'RIA, a modern t. of Sicily, in the province of Siracusa, 18 m. n.w. of Modica by railway on the Camarana. It possesses little interest, and is made only a resting-place for travelers. The soil of its vicinity, however, is fertile in fruits and wines; bee-culture is carried on; and there is an active trade in silk, and cattle. Pop. '81, 22,995.

VITTORIO, t. of n. Italy, in the province of Treviso, on the Meschio, a tributary of the Livenza. It was formed in 1879 by the union of the two towns Cenada and Serravalle, is an episcopal see, and has a cathedral and numerous handsome palaces and villas; pop. '81, 16,325.

VITUS, ST., DANCE. See CHOREA.

VIVA VOCE (Lat., "with the living voice"), freely rendered, signifies "aloud." A *viva voce* examination is an oral examination. A *viva voce* vote is one where the ayes and noes are given orally.

VIVANDIÈRE, in continental armies, and especially that of France, a female attendant in a regiment, who sells spirits and other comforts, ministers to the sick, marches with the corps, and contrives to be a universal favorite. Although a familiar friend to all, these women contrive to maintain themselves respectable, and generally respected; and a corps is usually extremely jealous of any discourtesy shown to its vivandière. The woman wears the uniform of the regiment, short petticoats replacing the man's tunic.

VIVE HENRI-QUATRE, historical French song, of doubtful authorship. The music has been assigned to Du Caurroy (1549–1609). It is supposed that it was a *Chanson à boire* of the time of Henri IV., and that Collé (1709–1783), made additions to it. During the Bourbon Restoration, it was chosen for the national anthem, and it was played at the Académie Royale de Musique as an overture to the opera on the day that the allied armies entered Paris, April 1, 1814. Paër wrote variations upon it, and Grétry introduced it into his opera, *La Magnifique* (1773), and Rossini into *Il Viaggio à Reims* (1825). See Grove's *Dictionary of Music and Musicians*.

VIVERRIDÆ are a family of semi-plantigrade carnivorous animals, embracing the *viverra* of Linnæus, who placed it between *felis* and *mustela*. The civets (*viverra*) of Cuvier are placed in the last edition of his *Règne Animal* between the dogs and hyenas, which are followed by the cats (*felis*). The genera and species are numerous. They are all of moderate size, with sharp muzzles and long tails, and are more or less striped, banded, or spotted. The dental formula of the genus *viverra* is

$$i\,\frac{3-3}{3-3};\quad c\,\frac{1-1}{1-1};\quad pm\,\frac{4-4}{4-4};\quad m\,\frac{2-2}{2-2}=40.$$

The upper fourth premolar and the lower first molar have cutting edges, while both the upper molars and the last lower molars have crowns faced with tubercles. The canines are long and sharp, and the tongue is very rough, with numerous hard, elongated papillæ; the claws are partially retractile, and on exposure to the light the pupils contract to a line. In most of their characters, therefore, the viverridæ are much more carnivorous than the mustelidæ, and have close affinities with the hyenas. Several species of the family have anal glands which secrete a peculiar odorous, fatty substance called *civet*. They all belong to the old world. An American genus, *bassaris*, was once referred to the family, but it is now known that the structure of its skull relates it to the rac-

coons. The true civet-cat is a native of n. Africa and eastern Asia. See CIVET.

Among other forms referred to the viverridæ, are the *mangusta* (ichneumon, q.v.), the genet (q.v.), the *suricate* (q.v.), the *paradoxurus*, the *mangue* or crossarchus of western Africa, and the *cryptoprocta* of Madagascar. The paradoxurus has much the character of the civets and genets. It has a tail capable of being rolled to its base, but it is not prehensile; toes five, nearly palmated; sole of foot tuberculous, applied throughout its surface to the ground. The *paradoxurus typus*, or paradoxure, was confounded by Buffon with the common genet (correction made by M. F. Cuvier). In form and habits it does not differ much from that animal, but the odoriferous pouch is absent. The tail is very peculiar. It is as long as the body, and depressed above and below. The extreme end when extended is turned over, bottom uppermost, and the animal can roll it up spirally from the extremity to the base. In the *crossarchus* the head is more rounded than in the ichneumons, and the muzzle is larger and movable. The pupil is round, and the tongue smooth on its edges, but rough and horny in the center. Pouch, secreting an unctuous, fetid, fatty matter. *Crossarchus obscurus* is nearly two feet long including the tail, which is about eight inches. The fur is composed of two kinds of hair, the external harsh, of a uniform brown, a little brighter on the head; cheeks pale. The genus *cryptoprocta* approaches more nearly than most of the other forms to the *felidæ*, having claws on both feet retractile, and furnished with the retractile ligaments. It has a slender body; strong limbs of moderate length; head narrow and slightly elongated; small glandular muzzle; nostrils with deep lateral sinus; numerous stiff whiskers; ears rather large and rounded, with a fold on the posterior margin and hairy within and without, except in the auditory passage; fore rather shorter than hind limbs; tail as long as body, reaching, when turned over, to the ears; soles on fore feet naked to carpus, on the posterior, to the heel; toes united nearly to the tips. *C. ferox* is a native of Madagascar.

VIVES, JUAN LUIS, LL.D., 1492–1540; b. Valencia, Spain; studied at Paris and Louvain; professor of the Latin language at Louvain; published a book at Paris in 1519 against the schoolmen; formed an intimate friendship at Louvain with Erasmus and Budæus; invited to England by Henry VIII., who made him tutor of the princess Mary, 1523; wrote for her two essays entitled *De Ratione Studii Puerilis Epistolæ Duæ;* imprisoned by order of Henry VIII. for opposing the divorce of queen Catharine of Aragon, 1528; when released went to Bruges. He wrote on philology, philosophy, and divinity. His principal works are *De Causis Corruptarum Artium; De Initiis Sectis et Laudibus Philosophorum; De Veritate Fidei Christianæ; De Anima et Vita;* commentaries on Augustine's *City of God*, the *Dream of Scipio*, the *Bucolics of Virgil.*

VIVIPAROUS FISH. It has been mentioned in the articles FISHES and REPRODUCTION that a few species of fishes are viviparous, or rather ovoviviparous, the eggs being hatched within the ovary. An example of this occurs in the viviparous blenny of the British coasts. See BLENNY. But it is the common characteristic of a whole family of the order *pharyngognathi*, therefore designated by the popular name of viviparous fish, and by the scientific name of *embiotocidæ*—a name formed from the Greek, and signifying *viviparous*. The general aspect of fishes of this family is somewhat perch-like; the scales are cycloid, the gill-covers are entire, the lips are thick. On the n.w. coast of America from San Francisco to Sitka, species of this family are very abundant. They come into shallow water near the coasts, when the time approaches for producing their young, which is about the middle of summer. They swim in vast shoals close to the surface, and have a peculiar habit of leaping high out of the water when alarmed, of which the Indians take advantage to capture them, by striking the water violently with their paddles, and uttering yells. The terrified fish leaping out of the water, many of them fall into the canoes. The Indians also capture these fishes by thrusting a spear with four barbed points into the midst of a dense shoal. They can be easily taken by nets, but are not of great value for the table.

VIVISECTION—a term which is employed to designate operations performed with the knife on living animals, with the view (1) of increasing our physiological knowledge; (2) of confirming previously known facts; and (3) of giving dexterity in operative surgery—is a course of procedure which may be traced back to almost the earliest periods of medicine and surgery, and was largely practiced in the Alexandrian school. It is, however, only comparatively lately—about half a century ago, when the barbarous experiments of Magendie, Brachet, and other distinguished French physiologists, became known in this country—that the subject has attracted much popular notice; and during the last ten years, attention has been so specially drawn to the atrocities systematically carried on in the great French veterinary colleges at Alfort and Lyons, that a deputation of "the royal society for the prevention of cruelty to animals" laid a statement of the facts before the emperor Napoleon. When it is stated that, with the nominal object of teaching the veterinary students at Alfort to become skillful operators, six living horses were supplied to them twice a week—that sixty-four operations were performed on each horse, and that four or five horses generally died before half the operations were completed—that it takes nearly two days to go through the list—and that all the old exploded operations, as well as those now practiced, were performed—and lastly, when

it is borne in mind that most, if not all, these operations could just as instructively have been practiced on the dead animal (as is done in this country), there cannot be a doubt that a vast amount of unwarrantable and gratuitous cruelty was carried on in these establishments. Although the subject was brought before the *Académie des sciences*, and warmly discussed, the final conclusion was "that the complaints of the London society are totally without foundation; and that there is no occasion to take any notice of them." We believe that it is only by the veterinary colleges of France that the view is advocated that vivisection is necessary for the purpose of giving dexterity in surgical operations.* But while all right-minded persons—except the majority of the members of the French academy, whose votes were probably influenced by a feeling of nationality—must concur in the view, that the argument in favor of vivisection utterly breaks down, some go further, and doubt whether any experiments on living animals, performed with the object of advancing medical and surgical knowledge, and of thereby relieving, indirectly, human suffering, or prolonging human life, are, on moral grounds, to be regarded as justifiable. In opposition to this view, it is maintained that, under certain circumstances, and with due restrictions, such experiments are not only justifiable, but their performance becomes a positive duty. It may be observed that, though in stating this controversy the term vivisection is retained, the remarks apply to all kinds of experiments on living animals. It is universally admitted that man may destroy animals for his food, and to furnish him with many of the necessaries and luxuries of life; and most persons go a step further, and see no impropriety in the pursuit of field-sports. Now, as Dr. Markham argues in his excellent prize essay on this subject, in all these cases of admittedly legitimate destruction of animal life, the infliction of pain is a necessary ingredient. In some modes of destruction, the death-blow is dealt at once, and the pain is but fleeting; while in others the agony of the death struggle is equivalent to a prolonged and painful torture. An ox may be at once stunned, while the animal bled to death suffers prolonged convulsive struggles. The humanitarian, if he be a sportsman, thinks little of the lingering pain which a wounded bird or broken-legged hare undergoes; nor, if he be engaged in the whale-fishery, does he lament over the prolonged suffering which the object of his pursuit must suffer before its capture. If, then, man can legitimately put animals to a painful death in order to supply himself with food and luxuries, why may he not also legitimately put animals to pain, and even to death, for the far higher and more noble object of relieving the sufferings of humanity, and of prolonging human life? To point out what gain has accrued to physiology (and hence, indirectly, to the healing art) by experiments on living animals, would occupy many pages of this work. It is sufficient to allude to the facts, that the doctrine of the circulation of the blood, and of the existence of, and circulation through, the lacteals, was thus established, and that nearly the whole of our present knowledge of the functions of the nervous system has been thus obtained, and could never have been afforded by the most minute anatomical research, and that in consequence of the knowledge thus obtained we no longer divide a motor nerve, and thus paralyze the face, in the hope of relieving tic douloureux; while on the other hand, thanks to the researches of Brown-Sequard, Bernard, and others, we can now see our way to a more rational mode of treating epilepsy, various obscure forms of paralysis, etc. Without vivisection, we could never clearly have understood the causes of the sounds of the heart, without the knowledge of which the stethoscope would have been useless in the diagnosis of cardiac diseases; nor should we have known anything of the true nature of that mysterious disease, diabetes. The Hunterian treatment of aneurism by ligature, which has saved hundreds of human lives, was worked out by experiments on living animals. The study of anæsthetics, which, after prolonged investigation, led to the introduction of chloroform (soon, possibly, to be superseded by some even less dangerous agent), was unquestionably accompanied by the suffocation of many animals; but surely no one who can form any estimate of the vast amount of misery which has been spared to humanity by the general introduction of the use of chloroform into surgical and midwifery practice, can regret the sacrifice. Indeed, the advantage of the discovery is experienced in more ways than one upon the lower animals, since the domestic animals are subjected to its beneficent influence when surgical operations are necessary, and since, in most cases, animals subjected to physiological experiments are now usually rendered insensible by it. If such questions as—the best means of restoring to life persons apparently drowned—why chloroform sometimes kills, and how those who are suffering under apparently fatal effects can be best recovered—admit, as they doubtless must, of a solution, that solution must be sought for in experiments on living animals. These and a multitude of similar considerations which might be adduced, are sufficient, it is maintained, to lead any unbiased inquirer to the conclusion that experiments on living animals, performed with the object of advancing medical, surgical, or toxicological knowledge, and of thereby indirectly relieving human suffering, or of prolonging human life, are not only justifiable, but a matter of duty.

At the meeting of the British association held at Liverpool in 1870, the general committee requested the committee of section D (Biology) to draw up a statement of their

* *Vivisection: is it necessary or justifiable?* (1866); *Physiological Cruelty* (?) (1883).

views on physiological experiments in their various bearings, and they further requested the committee to consider "from time to time whether any steps can be taken by them, or by the association, which will tend to reduce to its minimum the suffering entailed by legitimate physiological inquiries." Accordingly, at the meeting of the association at Edinburgh in 1871, the biological committee gave in a report, in which the following resolutions were presented: 1. That no experiment which can be performed under the influence of an anæsthetic ought to be done without it; 2. That no painful experiment is justified for the mere purpose of illustrating a law or fact already demonstrated; 3. Whenever, for the investigation of new truth, it is necessary to make a painful experiment, every effort should be made to insure success, so that the suffering inflicted may not be wasted—that, therefore, no painful experiment ought to be performed by an unskilled person, or in an unsuitable place; 4. In the scientific preparation for veterinary practice, operations ought not to be performed on living animals for the purpose of obtaining manual dexterity. On the reception of this report, a standing committee was appointed for the purpose of carrying out, with all the influence of the British association, the above humane suggestions.

A still more satisfactory result, however, was the interference (following upon the report of a royal commission) of parliament, which, in the year 1876, gave its assent to a bill to amend the law relating to cruelty to animals, the purpose of which was the restriction, or better regulation, of vivisection. The provisions of this act coincide to a great extent with the resolutions of the committee as given above, and require that every one performing a painful experiment upon a living animal (which must be with a view of advancing physiological knowledge, or knowledge which will be useful for saving or prolonging life, or alleviating suffering), must hold a license from one of her majesty's principal secretaries of state. Persons holding a conditional license are allowed to perform such experiments only in a registered place, while the same rule applies to experiments performed for the sake of instruction (which, however, are permitted only under certain stringent limitations). Special protection is afforded to horses, asses, mules, dogs, and cats.

The opponents of vivisection have labored with considerable zeal for some years past to secure legislation for its total prohibition. In the United States there are only three states, New York, New Jersey, and California, in which the statutes contain any direct reference to the subject. Of these three states, the statutes of New York are the most stringent. The first bill was passed in 1867, controlling the matter in a limited degree, while in 1882 a bill was introduced for its total suppression. This bill was introduced by Mr. Henry Bergh, who has been perhaps the strongest advocate against the practice in America. In England, more has been written against it even than in America, and attempts have been made there also to force legislation towards its total abolition. Of the many advocates against its practice in England, the name of Frances Power Cobbe stands most prominent, and a bill was introduced in Parliament, in 1883, but was not passed. The *Nineteenth Century*, *Fortnightly Review*, *Popular Science Monthly*, and some other magazines for 1881–1883, contain numerous articles both for and against vivisection. A movement has been made recently to procure a license for the British Institute of Preventive Medicine, in the interests of research in bacterial growths, but the movement has not as yet met with any success.

VIZAGAPATAM', a t. of British India, capital of the district of Vizagapatam, at the mouth of the river of the same name, on the w. shore of the bay of Bengal; pop., 40,000. It is near a promontory called *Dolphin's Nose*, a mountain 1500 ft. high. It has a good harbor and a large trade. It is a military station, but being unhealthful, Europeans have retired to Waltier, 3½ m. distant.

VIZIER, or Vizir (pronounced *viz-eer'*), the title of various high functionaries in the Ottoman empire, and other Mohammedan states. The word, which is of Arabic origin, and signifies "he who bears or supports (a burden)," was first bestowed as a title of honor on the chief-minister of the first Abbaside calif, in 750 A.D. During the decline of this dynasty, the vizier had to "bear the burden" of government almost entirely, and consequently, increased so much in power and authority, that the califs thought it prudent to counteract his influence by the creation of the new dignity of *Emir-al-Omrah* (q.v.), which, being generally bestowed upon one or other of the powerful alien princes who had made for themselves sovereignties in Persia, was found to be an efficacious counterpoise. The dignity of vizier was first introduced among the Ottoman Turks during the reign of their second sultan, Orkhan, and the title was exclusively confined to the sultan's prime-minister; but in 1386, it was conferred by Amurath I. on his victorious general, Timur-tâsh, and the prime-minister's title was then changed into *vizir-a-z'hem*, "grand or illustrious vizier." From this period, the number of viziers was gradually increased, but from the commencement of the 18th c., only seven of them were ministers. The title is now given, as is also that of mujir, to all the Turkish ministers of state. The grand vizier is, after the sultan, the most important personage of the Turkish empire; he unites in his own person the whole powers of the state, and is charged with a corresponding responsibility. The political changes introduced at the end of 1876 (by which Turkey became a "constitutional" monarchy) have not seriously affected the dignity of vizier, though in 1878 the title was abolished, that of president of

the council of ministers being substituted. This dignitary, whether under the old name or the new, is, after the sultan, the most important personage of the Turkish empire, and is the head of the administration ; but he is subject, as formerly, to more serious control from the intrigues of the palace than from the new constitution.

VIZZI'NI, a. t. of Sicily, in the province of Catania, stands on a hill. It is well built, and besides containing a college and hospital, there are a number of handsome buildings and churches, containing many fine pictures. Fruits in abundance are produced, and agates are found. Pop. '81, 14,191.

VLAARDINGEN, an unwalled t. in south Holland, lies about six m. w. from Rotterdam, on the left shore of the New Maas. It has a good haven, and sends annually a large fleet of vessels to the herring-fishing, besides carrying on a considerable shipping-trade with the Mediterranean, Norway, North America, Portugal, and Spain. The pop. Jan. 1, 1880, was 9520. Besides the herring and cod fishing, and shipping-trade, the industries are: ship-building, rope-spinning, distilling gin, sawing wood, grinding corn, boiling oil, tar, etc. Vlaardingen is one of the oldest towns in south Holland, the church now called the reformed church having been consecrated by Willibrod in the 7th c., but nearly rebuilt in 1744. It was the birthplace of the poets Arnold Hoogvliet (1687–1763) and Jacob van Dijk (1745–1828).

VLADIMIR', a government of Russia, bounded on the e. by the government of Nijni-Novgorod, and on the s.w. by that of Moscow. Area, 18,864 sq. m.; pop. '92, 1,476,118. The surface is level or undulating; the soil consists chiefly of clay or sand, and is fertile only in exceptional spots. The principal rivers are the Oka and its tributaries, of which the chief is the Kliasma, a navigable stream. Of the lakes, which are numerous, but of inconsiderable size, that of Pereislav is remarkable for its productive fisheries, and is famous in history as being the cradle of the Russian fleet. After St. Petersburg and Moscow, the government of Vladimir is the most actively industrious in the Russian empire, its manufactures including cotton-yarn and cloth, chintz and dyed goods, linen, glass, the product of numerous iron and brass foundries, chemicals and paper. The inhabitants are also much employed in painting images, and in knitting stockings, which are used in Russia and Siberia. The grain-crops raised are insufficient for local consumption, and corn is imported from neighboring governments. Hemp is successfully grown, and, besides being used in considerable quantities in local manufactures, is exported to Archangel and St. Petersburg. Forests, mostly of pine, form a border round the government; but do not occur in the interior. In the 9th c., the country was inhabited by Finns; and though it was subsequently conquered and settled by the Slavonians, traces of the original inhabitants are visible in the present population.

VLADIMIR', a t. of Great Russia, capital of the government of the same name, stands on the left bank of the Kliasma, which is high and wooded, 125 m. n.e. of Moscow. It was founded in the 12th c., during the ascendency of the dukes of Vladimir, and was the capital of Russia till 1328. It contains many historical remains, as the Kreml; the "Golden Gate," built in 1158; ruins of old fortifications, and many ancient churches, notably the Uspenskij cathedral, and the cathedral of St. Demetrius; an important ecclesiastical seminary, a public library, and a theater. There are several manufactures, and a trade in corn. Cherries are a considerable local product. Pop, '94, 18,936.

VLADIMIR', the name of two celebrated Russian princes, the former of whom, Vladimir Sviatoslavitch, was the first Christian sovereign of Russia. On the death of his father (972), Vladimir, though illegitimate, received Novgorod as his share of the heritage, but was driven out by Jaropolk, who had already murdered the third brother, Oleg. However, Vladimir, by the aid of a body af Varangians (from Scandinavia), returned and overcame Jaropolk, by whose assassination (980) he became sole ruler in Russia. Disembarrassing himself of his dangerous allies by persuading them to take service with the Byzantine emperor, he next recovered by force from the Poles the provinces of which they had deprived his brother, and subdued various tribes which had recently revolted. Russia at this time was an ill-compacted empire ; the various Slavic tribes which dwelt within its boundaries acknowledged the sovereignty of the Russian princes solely by the payment of tribute, and that only when the princes were powerful enough to enforce it ; hence it was the custom for the princes personally, or their delegates, to go their regular rounds after the fashion of tax-collectors, backed up by a large armed retinue. Vladimir tried to increase the central authority, and one of the means he adopted was the erection at his capital, Kiev, of the idol Perun (Thunder), the supreme divinity of the Slaves, and of the images of other inferior deities, Slave and Finnish. But a few years more effected a remarkable change ; many of Vladimir's subjects were Greek Christians ; his mother, Olga, had become one ; besides, he wished to be allied with the Byzantine imperial family, and moved by these and other reasons of personal or patriotic ambition, he resolved to turn Greek Christian. His mode of arriving at conversion and matrimony was as curious as effective ; he first made an attack upon the Byzantine empire, then sent an embassy to Constantinople, promising peace and his conversion, in exchange for the hand of Anna, the sister of Constantine IX., threatening war in case of refusal. His demands were gladly complied with ; and after his marriage and baptism at Kherson in 988, he returned to Kiev, destroyed all the idols, and commanded his subjects to be baptized. They had not the slightest objection to be baptized, if their feared and admired prince wished it; and for days the Dnieper was

crowded with applicants for the first testing ordinance of Christianity. It could hardly have been expected that a conversion managed in such a fashion would have affected the manners and conduct of such an arbitrary, violent, and daring prince as Vladimir; yet, strange to say, from 988 he appeared to have undergone a thorough mental and moral transformation; churches were built, schools established, capital punishment was supplanted by a fine, and such excessive lenity shown to all criminals that, in the interests of good government, it was found necessary to remonstrate with the thorough-going convert. Formerly, the wisdom and valor for which he was renowned were equaled by his licentiousness, so that the chronicles had more than one reason for saying that "he was like unto Solomon;" but the strictest chastity characterized the latter part of his life; and his charity to the poor, and personal forbearance, were extreme. He died in 1014, three years after his wife Anna. The Russian church has decreed him the epithets of "saint," and "equal of the apostles."—VLADIMIR II. VSEVOLODOVITCH, surnamed *Monomachus*, grand-prince of Kiev, the great-grandson of the preceding, was born in 1053. His father being a younger son, there seemed to be little chance of Vladimir's attaining power in the ordinary course of events, in his own country; and he accordingly led a band of auxiliaries to join Boleslas II. of Poland in his wars with Bohemia; gaining such renown, as on his return ranked him at the head of Russian warriors. Vladimir's father having, as the eldest of the Russian princes, succeeded to the grand principality of Kiev (1078), Vladimir took advantage of the opportunity to wrest from their lawful possessors, Smolensk, Tchernigov, and Novgorod; though some years afterward his cousin Oleg, the dispossessed prince of Tchernigov, with the aid of the Polotzee or Cumans (a Turkish nation which was at that time the terror of the Russians), recovered his dominion. Vladimir having subsequently routed the Polotzee in several engagements, became so extremely popular that in 1112 he was chosen grand-prince of Kiev, and for 13 years he displayed his eminent qualities as a ruler and a warrior. The maintenance of internal tranquillity, the improvement of old, and the building of new towns, and the encouragement of commerce, on the one hand; and the successful campaigns against the Tchudes, Poles, Polotzee, and Bolgars (a Mohammedan commercial people settled on the Volga), on the other, are the principal characteristics of his reign. Most of Vladimir's fame, however, rests on his writings, which present an interesting picture of the internal life of Russia in the 11th c., and indicate prominently the earnest practical influence of the newly introduced Christianity. Vladimir's mother was a daughter of Constantine Monomachus; and Alexis Comnenus, who wished to be on good terms with his powerful northern neighbor, is said to have sent him the crown, scepter, and sword of his grandfather, which are still shown as such, and which are employed in the coronation of the czar.

VLADISLAS, or ULADISLAS. See LADISLAS.

VLADIVOSTOK ("Mistress of the East," Chinese *Hai-stan-wai*), seaport and chief town on the eastern coast of Asiatic Russia, situated at the southern end of the Muravjev Amurstij peninsula, between the Golden Horn bay and the bay of Amur, in 43° 7′ n. lat., 131° 54′ long. w. from Greenwich. It is the seat of government for the province, terminal station for the trans-Siberian railway, now in course of construction; and is connected by telegraph with Shanghai through Nagasaki, Japan, and with Europe by way of Siberia. It already has a commerce of considerable importance, although the exports, chiefly in the hands of the Chinese, consist mainly of edible sea-weed, dried fish, reindeer horn and trepang. Pop. '90, 14,446, of which 9365 were Russians and 4193 Chinese. As railway terminus and headquarters for the Russian navy, Vladivostok is destined to become one of the most important cities of eastern Asia.

VODENA, a beautifully-situated t. of Turkey, in the province of Saloniki, on a mountain slope, 46 m. w.n.w. of Saloniki. Water is here very abundant; torrents rush headlong down the middle of all the streets. Pop. 8000.

VOGEL, EDOUARD, 1829–56; b. Crefeld; son of Johann Karl; educated at Leipsic, studied astronomy at Berlin with Encke, and was employed to assist Hind in Bishop's observatory, Regent's park, London. In 1853 he volunteered to go to central Africa to assist in the explorations of Overweg, Barth, and Richardson; visiting lake Tchad, Kuka, Yakova (publishing some account of his discoveries in German periodicals), and penetrated into the kingdom of Waday, where, in the town of Wara, in 1856, he was killed by order of the sultan. Previous search for him having proved unsuccessful, an expedition went out, in 1860, in charge of Von Heuglin. His sister, Elise Polko, published *Erinnerungen an einen Verschollenen* (1863), containing his notes.

VOGHE'RA, a city of northern Italy, in the province of Pavia, stands on the left bank of the Staffora, in a district rich in vineyards, orchards, and corn-fields, 24 m. e.n.e. of Alessandria by railway. The Via Emilia passes through the town and divides it into two parts. There are several handsome squares. Pop. '81, 10,785.

VOGT, KARL, b. Giessen, Hesse-Darmstadt, 1817, and there studied chemistry under Liebig. In 1833 he removed to Bern, studied medicine, and, after taking a degree, devoted much time to geology and zoology under Agassiz, becoming professor of natural history at Giessen in 1847. This chair he lost on account of his share in the political movements of 1848. He went to Switzerland, and in 1852 became professor of geology at Geneva, where he remained till his death. In 1861 he took charge of an expedition to the North Cape. His course of lectures *On Man: his place in Creation and in the History of the Earth*, have been translated into English, and he published other works of

high reputation. His latest work was his *Guide to Practical Comparative Anatomy*, written in collaboration with Prof. Young and published in 1885. He is best known and will probably be best remembered as a materialist of extreme views, and one of the first exponents in Germany of Darwinism, which he expounded with singular clearness and force. He d. in 1895.

VOICE (Lat. *vox*) may be defined as an audible sound produced by the larynx, and may be produced by any animal possessing that organ; while speech or articulate language may be regarded as voice modified in the cavity of the mouth. The larynx (q.v.) is the organ by which the so-called *vocal sounds* (or primary elements of speech) are produced. In the article LARYNX, it is shown that there are two groups of muscles, which respectively govern (1) *the pitch of the notes*, and (2) *the aperture of the larynx*. Those which affect the pitch of the notes are divisible into two antagonistic sub-groups, viz., (*a*) those which depress the front of the thyroid cartilage on the cricoid, and *stretch* the vocal ligaments; and (*b*) those which elevate the front of the thyroid cartilage, and *relax* the vocal ligaments; while those which control the aperture of the glottis are divisible into (*c*) those which *open* it, and (*d*) those which *close* it. It is only the first of these groups, viz., the muscles which stretch or relax the vocal ligaments, that is concerned in the production of voice. In the ordinary condition of rest there is a wide opening between the vocal ligaments, which are in a state of complete relaxation, and the air passes freely between them. For our knowledge of the appearances presented under varying conditions by the interior of the larynx, we are mainly indebted to prof. Czermak, the inventor of the laryngoscope (q.v.); and the reader who wishes to enter fully into this subject is referred to his work on that instrument, of which a translation was published by the New Sydenham society in 1861. The movements of the arytenoid cartilages during the production of vocal sounds can be distinctly seen—the views that had been previously deduced, from theory and experiments on the dead subject, being thus confirmed by ocular proof. As soon as we wish to utter a sound, the two arytenoid cartilages raise themselves in the fold of mucous membrane which covers them, and approach one another with surprising mobility. This movement effects the approximation of the vocal cords, and consequently the contraction of the glottis. It is impossible to study with the laryngoscope the mode of formation of the gravest chest-sounds, because the arytenoid cartilages become so raised that they almost come in contact with one another, while they bend under the border of the depressed epiglottis, and thus conceal the interior of the larynx. During the emission of the most acute sounds, the glottis contracts into a mere line, on each side of which the vocal cords may be recognized by their whitish-yellow color; while further outward, and separated from the former by a narrow groove, are the false or superior vocal cords of either side. The arytenoid cartilages are raised, and come in contact in the median line, the epiglottis is drawn outward, and a short stiff tube is then formed above the glottis; all these parts being, as we learn from our sensations during the experiment, in a state of very great tension. Independently, however, of such observations as those we have recorded from Czermak's interesting memoir, any one may easily prove for himself that the aperture of the glottis is much contracted during the production of sounds by comparing the time occupied by an ordinary expiration with that required for the passage of the same quantity of air during the maintenance of a vocal sound; moreover, the size of the aperture varies with the note that is being produced, as may be readily seen by any one who compares the time during which he can hold out a low and high note. When the distance between the vocal cords exceeds one-tenth of an inch, no sound can be produced.

How the vocal cords produce sounds is a question which has long attracted the attention of physiologists and physicists. To answer it they were compared with various musical instruments. More than a century ago Ferrein (*De la Formation de la Voix de l'Homme*, 1741) compared them to vibrating *strings;* and, at first sight, there is an apparent analogy; but on further investigation (for reasons which may be found in Carpenter's *Human Physiology*, 6th ed. p. 715), this view was found to be untenable. The analogues between the organ of voice and the *flute-pipe*, in which the sound is produced by the vibration of an elastic column of air contained in a tube, were then investigated, but found to fail. The third class of instruments with which the human organ of voice has been compared are vibratory *reeds* or *tongues*, which may either possess elasticity in themselves, or be made elastic by tension. From the experiments of Weber it appears that the action of the larynx has more analogy to that of *reed*-instruments than to the instruments previously named, and though there would seem at first sight to be a marked difference between the vocal ligaments and the membranous tongue of any reed-instrument, this difference is not very great. Müller ascertained that membranous tongues made elastic by tension may have three different forms, of which the following, which alone concerns us, is one: "Two elastic membranes may be extended across the mouth of a short tube, each covering a portion of the opening, and having a chink left open between them." Here there is clearly an approximation to the human glottis, which may be increased by prolonging the membranes in a direction parallel to that of the current of air, so that not merely their edges but their whole planes shall be thrown into vibration. Prof. Willis has, upon this principle, invented an *artificial glottis*, in

which the vocal ligaments are imitated by leather, or preferably by sheet india-rubber. It is composed of a wooden pipe of the form of fig. 1, *a*, having a foot, C, like that of an organ-pipe, and an upper opening, long and narrow, as at B, with a point, A, rising at one end of it. A piece of leather or sheet india-rubber doubled round this point, and secured by being bound at D with strong thread, will form an artificial glottis, *b*, while its upper edges, G, H, are capable of vibrating or not by inclining the planes of the edges. Two pieces of cork, E and F, are glued to the corners to make them more manageable. From this machine various notes may be obtained by stretching the edges of the leather in the directions of their length, G, H; the scale of notes yielded by leather is much more limited than that yielded by india-rubber; and other observers have found that the middle coat of the arteries in a moist state (as being more elastic, and almost identical in structure with the vocal ligaments), yields more satisfactory results even than india-rubber. "It is worthy of remark," as Dr. Carpenter observes, "that in all such experiments it is found that the two membranes may be thrown into vibration, when inclined *toward* each other in various degrees, or even when they are in parallel planes, and their edges only approximate; but that the least inclination *from* each other (which is the position the vocal ligaments have during the ordinary state of the glottis) completely prevents any sonorous vibrations from being produced."—*Op. cit.*, p. 718. The *pitch* of the notes produced by membranous tongues may be affected in various ways (as by increasing the strength of the blast, the addition of a pipe, etc), and is mainly governed by their degree of tension, while the foregoing statements show that the sound of the voice is the result of the vibrations of the vocal ligaments which take place according to the same laws with those of elastic tongues generally. Little is, however, known with certainty regarding the mode and degree in which the tones are modified by the shape of the air-passages generally, the force of the blast of air, and other circumstances.

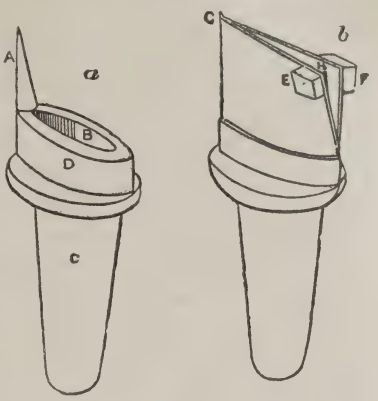


Fig. 1.

The *falsetto* is a peculiar modification of voice, differing from the ordinary or *chest voice*, not only in the higher pitch of the notes, but also in their quality. The theory of its production is still an open point, into which we have not space to enter further than to remark that, according to prof. Wheatstone, falsetto notes are to be explained by supposing that "the column of air in the trachea may divide itself into *harmonic lengths*, and may produce a *reciprocation* of the tone given by the vocal ligaments."

The pressure of the air within the trachea during the production of voice is very considerable. From observations made by Cagniard-Latour on a man with a fistulous opening in the trachea, it was found that, when the patient called out at the top of his voice, the pressure was equal to that of a column of water 38 in. in height; when he spoke at his usual pitch, to one of 5 in.; and, when he sang in a high note, to one of about 8 inches. The glottis has been well chosen by Dr. Carpenter to illustrate the minute precision with which the degree of muscular contraction can be adapted to the desired effect. The musical pitch of the tones produced by it is, as we have shown, regulated by the degree of tension of the elastic vocal ligaments. Their average length, in a state of repose, is $\frac{7\,3}{1\,0\,0}$ of an inch; while in the state of greatest tension it is about $\frac{9\,3}{1\,0\,0}$—the difference being thus *one-fifth* of an inch; while in the female the respective lengths are $\frac{5\,1}{1\,0\,0}$ and $\frac{6\,3}{1\,0\,0}$ respectively—the difference being thus about *one-eighth* of an inch. Now the natural compass of the voice, in persons who have cultivated the vocal organ, is about two octaves, or 24 semitones. Within each semitone an ordinary singer could produce at least 10 distinct intervals (the celebrated Mme. Mara could sound 100 different intervals between each tone, the compass of her voice being 21 tones), so that 240 is a very moderate estimate of the number of different states of tension of the vocal cords, every one of which can be produced at will; and the *whole* variation in the length of the cord being not more than one-fifth of an inch, even in man, the variation required to pass from one interval to another will not be more than $\frac{1}{1\,2\,0\,0}$ of an inch (while in such a case as that of Mme. Mara the distance would be reduced to $\frac{1}{1\,7,0\,0\,0}$ of an inch).

In the production of vocal sounds, the delicate adjustment of the muscles of the larynx, which is requisite to the evolution of determinate tones, is directed by the sense of hearing, being originally learned under the guidance of the sounds actually produced; but "being subsequently effected voluntarily, in accordance with the mental conception of the tone to be uttered, which conception cannot be formed unless the sense of hearing has previously brought similar tones to the mind. Hence it is that persons who are born *deaf* are also *dumb*. They may have no malformation of the organs of speech, but they are incapable of uttering distinct vocal sounds, or musical tones, because they have not the guiding conception, or recalled sensation, of the nature

of these. By long training, however, and by imitative efforts directed by muscular sensations in the larynx itself, some persons thus circumstanced have acquired the power of speech; but the want of a sufficiently definite control over the vocal muscles is always very evident in their use of the organ."—*Op. cit.*, p. 556. A fund of interesting matter in connection with this subject may be found in Dr. Kitto's *Lost Senses*. Although not born deaf, he became *completely* so in early childhood, in consequence of an accident. His voice became similar to that of a person born deaf and dumb, and taught to speak. It was observed that the words which he had been accustomed to use before his accident, were still pronounced as they had been in childhood, the muscular movements concerned in their production having been still guided by the original auditory conception, while all the words subsequently learned were pronounced according to the spelling.

The various muscular actions which are concerned in the production of vocal tones, are commonly regarded as being under the influence of the will. It is, however, easy to show that this is not the case. We cannot, by simply *willing* to do so, raise or depress the larynx, or move one cartilage of it toward or from another, or extend or relax the vocal ligaments; although "we can readily do any or all of these things by an act of the will, exerted for a specific purpose. We conceive of a tone *to be* produced, and we *will* to produce it; a certain combination of the muscular actions of the larynx then takes place, in most exact accordance with one another, and the predetermined tone is the result. This anticipated or conceived sensation is the guide to the muscular movements, when as yet the utterance of the voice has not taken place; but while we are in the act of speaking or singing, the contractile actions are regulated by the present sensations, derived from the sounds as they are produced." From these remarks, in which Dr. Carpenter has placed a very difficult subject in as clear a light as the subject admits of, it follows that the muscular actions which are concerned in the production and regulation of the voice, are due to an *automatic* impulse, similar to what occurs in the movements of the eyeball, and in many other cases that might be adduced. There cannot be a doubt that the simple utterance of sounds is in itself an instinctive action; although the combination of these sounds into music or into articulate language, is a matter of acquirement.

Having explained the way in which the larynx produces those *tones* of which the voice fundamentally consists, and the sequence of which becomes *music*, we come to the subject of *speech*, which consists, in the modification of the laryngeal tones by other organs superior and anterior to the larynx (as the tongue, the cavity of the fauces, the lips, teeth, and palate, with its velum and the uvula acting as a valve between the throat and nostrils), so as to produce those *articulate sounds* of which language is formed. The organ of voice is thus capable of forming a large number of simple sounds, which may be combined into groups, forming words. Vocal sounds are divided into vowels and consonants. When a vowel is pronounced what happens? This question is thus answered by Prof. Max Müller: "Breath is emitted from the lungs, and some kind of tube is formed by the mouth, through which, as through a clarionet, the breath has to pass before it reaches the outer air. If, while the breath passes through the vocal cords, these elastic *laminæ* are made to vibrate periodically, the number of their vibrations determines the pitch of our voice, but it has nothing to do with its *timbre*, or vowel. What we call vowels are neither more nor less than the qualities, or colors, or *timbres* of our voice, and these are determined by the form of the vibrations, which form, again, is determined by the form of the buccal tube."—*Lectures on the Science of Language*, 2d series, p. 116. This writer enters very fully into the various configurations of the mouth requisite for the formation of the different vowels. (1.) In pronouncing *u* (the vowels are all understood to be pronounced as in Italian), we round the lips, and draw down the tongue, so that the cavity of the mouth assumes the shape of a bottle without a neck. (2.) If the lips are opened somewhat wider, and the tongue be somewhat raised, we hear the *o*. (3.) If the lips are less rounded, and the tongue somewhat depressed, we hear the *a* of the northern languages (as in *august*). (4.) If the lips are wide open, and the tongue in its natural flat position, we hear *a*. (5.) If the lips are fairly open, and the back of the tongue raised toward the palate, the larynx being raised at the same time, we hear the sound *e*. (6.) If we raise the tongue higher still, and narrow the lips, we hear *i*. The buccal tube here represents a bottle with a very narrow neck, of no more than six centimeters (or about 2¼ in.) from palate to lips. Diphthongs arise when, instead of pronouncing one vowel directly after another with two efforts of the voice, we produce a sound *during* the change from one position to the other, that would be required for each vowel. Though the tube of the mouth thus modified by the tongue and lips is the chief agent in the production of vowels, Czermak has proved that the *velum palati* is changed in position with each vowel, and that it is lowest for *a*, and rises successively with *e*, *o*, *u*, and *i*, when it reaches its highest point. He likewise found that the cavity of the nose is more or less opened during the pronunciation of certain vowels. Languages might have been formed entirely of vowels, but the existing words, consisting solely of vowels, show how unpleasant such languages would have been. Something else was obviously wanted to supply what Max Müller happily terms *the bones of language*—namely, the consonants. These are commonly divided into (1) those which require a total stoppage of the breath at the moment previous to their being produced,

and which cannot, therefore, be prolonged; and (2) those in pronouncing which the interruption is partial, and which, like the vowel sounds, can be prolonged at pleasure. The former are termed *explosive*, and the latter *continuous*, consonants. In pronouncing the *explosive* consonants, the posterior openings of the nostrils are completely closed, so as to prevent the passage of air through the nose, and the current may be checked in the mouth in three ways—viz. (*a*) by the approximation of the lips; (*b*) by the approximation of the point of the tongue to the front of the palate; and (*c*) by the approximation of the middle of the tongue to the arch of the palate. The letters *b* and *p* are pronounced by the first of these modes; *d* and *t* by the second; and *g* (hard) and *k*, sounded as *key*, by the third; the difference between *b*, *d* and *g*, on the one hand, and *p*, *t* and *k*, depends upon the approximating surfaces being larger, and the breath being sent through them more strongly at the moment of opening in the former than in the latter group. The *continuous* consonants may be subdivided into three classes, according to the degree of freedom with which the air is allowed to escape, and the compression which it consequently experiences. In the *first* class no air passes through the nose, and the parts of the mouth that produce the sound are closely approximated, so that the compression is considerable. This is the case with *v* and *f*, *z* and *s*, *d* and *t*, *th*, *sh*, etc., the movement of the tongue being also concerned in the production of several of these sounds. In the *second* class, including *m*, *n*, *l*, *r*, the nostrils are not closed, and, consequently, the air is scarcely at all compressed. In pronouncing *m* and *n*, the breath passes through the nose alone; *m* is a labial, like *b*, but the latter is formed with the nose closed. Hence the passage of *m* to *b* (as in *lamb*) is easy: so also is that from *n* to *t*, or from *n* to *g*, as is seen in the frequent combination of *nt* and *ng* in most languages. The sounds of *l* and *r* (letters which Max Müller places in a special group under the name of trills) are produced, according to Helmholtz, as follows: "In pronouncing *r*, the stream of air is periodically entirely interrupted by the trembling of the soft palate, or of the tip of the tongue, and we then get an intermittent noise, the peculiar jarring quality of which is produced by these very intermissions. In pronouncing *l*, the moving soft lateral edges of the tongue produce, not entire interruptions, but oscillations in the force of air."—*Die Lehre von den Tonempfindungen*, 1863, p. 116. The *third* class contains sounds which scarcely deserve to be called consonants, since they are merely *aspirations*, either simple, or modified by an elevation of the tongue, causing a slight obstruction to the passage of air, and an increased resonance in the back of the mouth. The present *h* and the Greek *χ* are examples of these sounds.

For further details, the reader is referred to the admirable chapter on "Voice and Speech" in Carpenter's *Human Physiology*, and to Max Müller's *Lectures on the Science of Language* (from both of which we have borrowed largely in this article), to Mr. Bishop's article "Voice" in the *Cyclopædia of Anatomy and Physiology;* and the various works of Funke, Helmholtz, Brücke, Czermak, Du Bois Reymond, etc., mentioned by Max Müller in his chapter on "the Physiological Alphabet."

VOIDED, in heraldry, a term applied to an ordinary when its central area is removed, so that the field is seen through it, and little but a mere outline remains.—Azure, a saltire voided argent.

VO'LANT, in heraldry, flying.

VOLANTE, a cumbrous two-wheeled vehicle, in common use in the streets of Havana. It admits of but two, or at most three occupants, and the horse which drags it is usually driven by a negro "calesero" or coachman, who rides on another horse fastened to the whiffletree by a pair of traces. The volante, of late years, has lost much of its popularity, and there are signs that it may entirely disappear.

VOLAPÜK (*vol*, world, and *pük*, language), the invention of Rev. Father Johann Martin Schleyer, a Roman Catholic priest, b. in Ober-Lauda, Baden, but now a resident of Constance. Father Schleyer began his labors in 1878, and in 1879 published a grammar and dictionary, but it was not till 1884 that societies for the study of V. were formed outside of Germany and Austria. In 1885 V. was introduced into France by Prof. Auguste Kerckhoffs, who improved and simplified it, and its use has extended so rapidly that a number of periodicals are now published in the language. The characteristics of the grammar are regularity and simplicity, and it may be learned in a few days. Schleyer's dictionary contains only 13,000 words. About one-third of the words are derived from English and French roots, and root-words are mostly monosyllabic. The alphabet contains 8 vowels and 19 consonants. There are four cases: the genitive, dative, and accusative being made by adding the vowels *a*, *e*, *i* to the nominative (*dom*, a house, *doma*, of the house); the plural invariably ends in s. Verbs are active, passive, and reflective, and the root is generally a substantive (*pük*, language, *pükon*, to speak). Articles are omitted; adjectives, verbs, and adverbs are regularly formed from the substantive, and have invariably the same termination. There are no artificial genders, no irregular verbs, and there is but a single conjugation. The promoters of V. hold frequent congresses. There is a general association of which Schleyer is head (*cifal*), an academy, under Kerckhoffs, and a central organ, published at Constance.

VOLCA'NOES are openings in the earth's crust from which various kinds of matter in a highly heated condition are ejected, such as gases, steam, ashes and cinders, masses of solid rock, and molten rock called lava. The heavier portions of the materials thus ejected fall back within and around the vent, thus in time building up the hilly or mountainous cones by which volcanoes are in general distinguished. The depression

in the top of these conical formations is called the crater; and the appearance of burning and of vomiting forth flame and smoke, peculiar to volcanoes in action, is not caused by external combustion, but is simply the fiery reflection thrown upon the ascending volumes of steam and vapor from the incandescent materials within the vent. Volcanic structures are likewise formed in the ocean. In 1796 a column of smoke was seen to rise from the Pacific ocean about 30 m. to the n. of Unalaska. The ejected materials having raised the crater above the level of the water, flames issued from the islet, which illuminated the country for 10 m. around. Six years afterward, when a few hunters landed on the new island, they found the soil in some places so hot that they could not walk upon it. Repeated eruptions have increased the dimensions of the island, until now it is several thousand feet in height, and between 2 and 3 m. in circumference. In the same region is the volcanic island of Kliutschewsk, which rises at once from the sea to the enormous height of 15,000 feet.

The lava, scoriæ, and ashes which are thrust out of the crater form highly inclined and more or less regular beds on the surface of the mountain, extending from the crater-mouth to varying distances down the sides of the volcano. This method of increase gives the uniform conical outline to volcanoes, without the terraces or breaks which are found in almost all other mountains. The sides are often furrowed longitudinally by straight narrow ravines, which increase in number toward the base. These are produced by the action of running water obtained from rain or from melting snows during an eruption. The rapidity with which floods rush down the steep sides of a volcano gives a prodigious force, which the loose scoriæ and ashes, and even the solid lava, cannot resist.

The grayish color of volcanic mountains is produced by the ash and scoriæ, which, though in composition the same as the dark lava, have this lighter color from the minute subdivision of their particles. When a particular series of rocks remain on the surface, and are not covered by the products of more recent eruptions, they weather and decompose, and produce a very fertile soil, which is speedily clothed with vegetation, and thus change the whole aspect of the formerly bare and uniformly-colored mountain.

The vent through which the materials are vomited forth is called the crater. This is a more or less circular opening, communicating with the source from which the ejected materials are obtained. The crater has generally one side much lower than the other—that from which the prevailing wind blows, which carries with it the showers of ashes to the opposite side of the mountain. In many cases, the cone is truncated; a wide hollow of immense extent, and often of great depth, in the base of which the crater is situated, occupies the summit. The Spanish name *caldera* is technically applied to these hollows. Their origin has been a subject of considerable controversy. Von Buch and others maintain that they are craters of elevation; that is, that the rocks were originally spread out in nearly horizontal deposits, and then upheaved into a dome-shaped mountain, with the hollow caldera in the center of its summit. The more satisfactory explanation is that the original cone, formed by the alternate deposition of the lava and ashes ejected from the crater, has, from the great heat of the molten lava rising in the tube of the volcano, or from gaseous explosions, given way, and fallen in. The cones both of Etna and Vesuvius have frequently fallen in and been reproduced. In 1822 the summit of Vesuvius was reduced by 800 feet. The immense size of some calderas seems, however, opposed to this theory. That of the island of Palma, one of the Canaries, is from 3 to 4 geographical m. in diameter, and the precipices which surround the cavity are from 1500 to 2,000 ft. in vertical height. They form an unbroken wall, except at the south-western end, where a deep gorge permits the passage of the torrent which drains the caldera. The precipices are traversed by numerous vertical dikes, and exhibit all the appearances which would be produced by the falling-in of the huge summit of this once enormous volcano.

The pressure of the incandescent lava often forces for itself a passage to the surface before it reaches the mouth of the crater, and this is more frequently the case when the volcanic eruption is accompanied with earthquakes. Immense vertical fissures are found radiating from the center of the volcanic action, and reaching the surface of the ground, and even rising to the summit of the mountain; these being filled with the molten rock, which in course of time solidifies and forms often a large portion of the mountain mass, as is shown in the Val del Bové on Etna (q.v.). The lava sometimes pours out of these fissures instead of rising to the crater. In 1783 during a terrible eruption of Hecla, a prodigious stream of lava flowed from a lateral crevice; moving slowly down the mountain-side, it reached a distance of 50 m. in 42 days; it then branched into two main streams, the one running 40 m. and the other 50 m. further toward the sea. Its depth varied from 600 to 1000 ft., and its greatest width was 15 miles. The amount of lava poured out into this stream would almost equal Mont Blanc in bulk.

The power which exhausts itself in the eruption of a volcano often shows itself by changes which it produces in the level of the country around. About a hundred years ago, a volcano appeared in the center of the great table-land of Mexico, and raised an area of nearly 4 sq.m. 550 ft. higher than it was before, covering it at the same time with conical hills of various heights, the highest of which is Jorulla, which is 1600 ft. high. But sometimes a subsidence takes place. In 1772 a great part of the Papandayang, a mountain in Java, was swallowed up; the inhabitants of its declivities were sud-

denly alarmed by tremendous noises in the earth, and before they had time to retire, the mountain began to subside, and soon disappeared. The area thus sunk was 15 m. long and 6 broad.

A volcanic eruption is generally preceded by rumbling noises and slight movements in the earth; then fitful puffs of gases and steam are given off. These contain much sulphur; and some volcanoes give out such quantities of carbonic acid and other mephitic gases as to destroy the animals in the neighborhood. See Upas. The eruption itself begins, perhaps, with the ejection of the finest dust, and that with such a force as to project it high into the atmosphere, where, taken up by air-currents, it is often carried to enormous distances. In 1845, the dust from Hecla was in ten hours thickly deposited on some of the Orkney and Shetland islands; the ashes from Conseguina fell, in 1835, on the streets of Kingston, Jamaica, at a distance of 700 m.; and during the same eruption, the fine dust covered the ground at a distance of 30 m. to the s. of the volcano, to a depth of more than 10 ft. During or after the stupendous eruption of the volcano on the island of Krakatoa, in the Straits of Sunda (which was accompanied by a destructive earthquake wave that swept the shores of Sumatra and Java), dust and mud were thickly deposited over an enormous area. Remarkable solar phenomena in Ceylon, South Africa, Brazil, and elsewhere, were attributed to the presence in the upper atmosphere of volcanic dust from this source; and, in the U. S., deeply-colored skies before sunrise and after sunset, months after the eruption, were held to be due to the same cause. Sediment left, in Europe, on windows after rain, and on snow, was chemically tested, and found unmistakably to contain volcanic dust.

The flames seeming to issue from the crater are usually the reflection of the glowing lava emitted from the crater, and illuminating the clouds of vapor and ashes.

Lava and scoriæ are at last vomited forth. Sir William Hamilton says that, in 1779, the jets of liquid lava from Vesuvius, mixed with scoriæ and stones, were thrown to a height of 10,000 feet, giving the appearance of a column of fire. The lava, however, generally issues from openings in the side of the mountain. It pours forth in a perfectly liquid state, bright and glowing with the splendor of the sun. At first, it flows rapidly; but as its surface becomes cooled and converted into slag, its velocity diminishes. It has to burst the indurated coating before it can continue its progress, and the liberated lava when it flows bears on its surface masses of scoriæ, looking like the slag from an iron furnace.

The mineral and chemical constituents of the various materials ejected by volcanoes have recently been carefully studied, and much valuable information on this and the kindred subject of the causes of volcanic action will be found in Prof. Judd's work, *Volcanoes: What they are and what they teach.*

The theories propounded to account for volcanic action are either chemical or geological. Sir H. Davy suggested that if immense quantities of the metallic bases of the earths and alkalies were present in the interior of the earth, all the phenomena would be produced by their oxidization from contact with air or water. Although the distinguished author of this theory abandoned it, it has since been taken up and advocated by Daubeny and others. Bischof, assuming that the interior of the earth consists of a highly heated and fused mass, considers that the mechanical action of water, converted into steam by the great heat, would produce volcanic action. Both theorists seek support for their views from the fact, that the great majority of volcanoes are situated on or near the sea-coast. Geologists accepting also the doctrine of internal heat, and believing that at a certain depth the rocks of the earth are, partially at least, in a state of fusion, explain volcanoes by considering them as connections established between the interior of the earth and the atmosphere, the elastic force of steam being the propelling power. Darwin, from observations made in all parts of the world, believes that volcanoes are chiefly, and, indeed, almost only, found in those areas where subterranean motive-power has lately forced, or is now forcing upward, the crust of the earth, and are invariably absent in those where the surface has lately subsided, or is still subsiding.

Volcanic action is limited to particular regions of the earth. In these regions, the active vents are distributed at intervals, and are generally arranged in a linear direction. The Pacific ocean is bounded by an almost unbroken line of active volcanoes. Beginning in the New South Shetlands, where there is an active volcano in lat. 62° 55′ s., we pass to Terra del Fuego, and then on to the Andes, which are throughout their whole course volcanic, although the great centers of present action are confined to Chili, Peru, the neighborhood of Quito, Guatemala, and Mexico. The line is continued northward by the burning mountains of north-western America, and the Aleutian islands carry the chain across to Kamtchatka on the Asiatic side. Here, turning southward, the line may be traced through the Kurile islands, Japan, Formosa, the Philippines, Moluccas, New Guinea, and the Salomon and New Hebrides groups, to New Zealand. From Celebes, a branch proceeds in a north-westerly direction through Java and Sumatra, to Barren island in the bay of Bengal; and even beyond this we find a region in northern India subject to earthquakes, which may lead us, on the one hand, to the volcanic region in Tartary, or, on the other, through Asia Minor to the Greek archipelago, Sicily, Naples, and on to the Canaries and cape de Verd. According to the geological theory, the lines thus traced over the globe would represent rising lands, where the crust is less strong, and so less liable to repress the expansive powers below. There are a number of isolated volcanoes also scattered over the surface of the earth. These are supposed to have opened a star-shaped communication with the interior. The most remarkable of

these isolated volcanoes are Jan Mayen, in lat. 70° 49′ n., and those in Iceland in the north, and mount Erebus in s. Polarland, in lat. 77° 32′ s.

The volcano is a conspicuous object of scientific inquiry, inasmuch as its action embraces all the phenomena connected with the expulsion of heated materials from the interior of the earth to the surface. Volcanoes may break through any kind of geological formation. In Auvergne, in the miocene period, they burst through the granitic and gneissose plateau of central France; in the period of the lower old red sandstone they pierced Silurian rocks in Scotland; in the late tertiary and post-tertiary ages they found their way through the marine strata, and formed such huge piles as Etna and Vesuvius; on the banks of the Rhine they have penetrated some of the older alluvia of the river. In many instances new volcanoes have appeared on the site of old ones. In Scotland the carboniferous volcanoes have risen on the sites of those of the old red sandstone. Somma and Vesuvius have arisen from the great Neapolitan plain of marine tufa. It is usual to class volcanoes as active, dormant, and extinct. The active volcano cannot be mistaken; but in many cases it is impossible to determine whether a volcano is extinct or only dormant. The volcanoes of the Silurian age in Wales, of the carboniferous age in Ireland, of the Permian age in the Hartz, and of the miocene age in the Hebrides, are certainly extinct. But the miocene volcanoes of Iceland are still represented by Skaptar-Jökull and Hecla. Somma, in the first century of the Christian era, would have been regarded as an extinct volcano; its fires had never been known to have kindled; its vast crater was a wilderness of vines and brushwood, the haunts of the wild boar and the wolf. Yet in the autumn of the year 79 A.D., half of the wall of the crater was blown out by a series of terrific explosions, the present Vesuvius was formed within the limits of the old crater, and the cities of Pompeii and Herculaneum were buried. From that day to the present the volcano has been active, although there have been long intervals of quiet. Between the years 1500 and 1631 it was entirely dormant, and the crater was overgrown with vines and brushwood. Near the close of 1631, however, there came an eruption never equaled except by the one of 79.

The materials thrown up by volcanic action are: 1. Gases; 2. Lavas; 3. Fragmentary substances. Gases and vapors are the earliest development, and steam is the most abundant of all. In great eruptions it rises in enormous quantities and rapidly condenses into rain. It has been calculated that in a hundred days Etna threw up enough vapor to make 200,000,000 barrels of water. This vapor is mixed with various materials, the most abundant being sulphureted hydrogen, which is the chief cause of the deposits of sulphur around vents. At Vesuvius and some other volcanoes hydrochloric acid appears. Carbonic acid is sometimes given off so abundantly that birds and small animals have been suffocated by it. Nitrogen has also been detected. With these gases and vapors are associated many substances which, sublimated by the volcanic heat, appear as deposits along crevices and surfaces where they reach the air and are cooled. These are sulphur, sal-ammoniac, specular iron, oxide of copper, boracic acid, and the chlorides of sodium, iron, copper, and lead. The chloride of sodium is sometimes so abundantly deposited as to form valuable mines of salt. Among the phenomena of volcanic action may be mentioned the abundant discharge of water. The sources of such water are melting snow, the condensation of the great volumes of steam, and the disruption of reservoirs of water in subterranean recesses. The volcanoes of South America often throw up great quantities of dead fish, which seems to indicate a connection with the ocean. There is a volcano in Guatemala that throws out nothing but water. In one of the volcanoes of Java there is a hot steaming lake of acid water. Early in 1817 an eruption took place by which great destruction was caused. After the explosion the temperature of the water in the basin was greatly reduced. Sometimes the water and the dust are thrown up united and form what are known as mud volcanoes; but these are rare.

One of the greatest products of volcanic action is lava, by which is meant the molten matter which flows from the mountain. When cooled, lava is a light porous stone of sp.gr. 2.37 to 3.22, containing a variety of mineral substances. Lavas differ greatly in texture; some are crystalline, some are half glassy or stony; others are vitreous. They also vary in color and in general external aspect. Their surface is commonly rough and rugged until it has been sufficiently decomposed to crumble into excellent soil, which, under favorable circumstances, will support a luxurious vegetation.

Volcanic action may be either constant or periodic. Stromboli in the Mediterranean has been uninterruptedly emitting hot stones, steam, and lava from the dawn of history. Other constant volcanoes are known in the Moluccas and the Friendly Islands. The cone of Sangay in Quito perpetually gives off hot vapors, and Cotopaxi in Mexico is constantly active. But the general rule is that a volcano has intervals of greater or less fury, and followed by intervals of quiescence. The eruptions of Vesuvius are often preceded by a failure or diminution of the wells and springs in the neighborhood; but more frequent indications of an approaching outburst are conveyed by sympathetic movements of the ground beneath. Rumblings and groanings are heard from below; slight tremors succeed, increasing in frequency and violence till they become distinct earthquake shocks. The vapors from the crater rise more abundantly into the air. All this time the lava column in the pipe or funnel of the volcano has been slowly ascending, forced upward and kept in perpetual agitation by the passage of the elastic vapors through its mass. After a long interval of quiescence has elapsed, the vent may contain much solid lava which will confine the melted part beneath. A vast pressure is thus

exerted on the sides of the cone. Should these be too weak to resist, they will open in one or more rents, and the liquid lava will issue from the outer slope of the mountain; or the energies of the volcano will be directed toward clearing the obstruction in its throat, until, with tremendous explosions, and vast clouds of dust and fragments, the bottom and sides of the crater are blown out, and the top of the cone disappears. The lava may now pour over the lowest part of the lip of the crater, while, at the same time, immense quantities of red-hot bombs, scoriæ, and stones are shot up into the air, most of them falling back into the crater, but many descending upon the outer slopes of the cone, and some even upon the country beyond the base of the mountain. The lava rushes down at first like a river of molten iron, but, as it cools, its rate of motion lessens. Clouds of steam rise from its surface, as well as from the central crater. Indeed, every successive paroxysmal convulsion of the mountain is marked, even at a distance, by the rise of huge ball-like wreaths or clouds of steam mixed with dust and stones, forming a vast column which towers sometimes a couple of miles above the summit of the cone. By degrees these diminish in frequency and intensity. The lava ceases to flow, the shower of stones and dust dwindles down, and after a time, which, with the same mountain, may vary from hours to days or months, the volcano becomes tranquil.

The violence of volcanic explosions is remarkable. The history of the cone of Vesuvius brings before us a long series of such explosions beginning with that in 79 A.D., which was the greatest known in human history. Even now, in spite of all the ashes and lava poured out during the last 1800 years, it is easy to see how stupendous must have been that explosion by which the southern half of the crater was blown out. At every successive important eruption a similar operation takes place within the present cone. The hard cake of lava forming the floor is burst open, and with it there usually disappears much of the upper part of the cone, and sometimes, as in 1872, a large segment of the crater wall. In 1538 a new volcano was formed on the shores of the bay of Naples. A cavity was made by successive explosions and such quantities of stones, scoriæ, and ashes thrown from it as to form a hill 440 ft. above the sea level and more than 8,000 ft. in circumference. Showers of dust and stones are a conspicuous feature of volcanic eruptions. Instances are known where stones eight pounds in weight have passed through enormous parabolic curves in the air and fallen at a great distance. Such stones are found in the ashes that entombed Pompeii. But in many great eruptions, besides a constant shower of stones and scoriæ, a vast column of exceedingly fine dust rises out of the crater, sometimes to the height of more than a mile, and then spreads outward like a sheet of cloud. So dense sometimes is this dust-cloud that the sun is obscured, and for days together the darkness reigns for miles around the volcano. In 1822 this was the case at Vesuvius, the ashes not only falling thickly on the villages around the base of the mountain, but traveling as far as Ascoli, 56 Italian m. from the mountain on one side, and to Casona, 105 m. away on the other side. But probably the most stupendous outpouring of volcanic ashes on record was that which took place after a quiescence of 26 years from the volcano of Conseguina, in Nicaragua, during the early part of 1835. On that occasion utter darkness prevailed over a circle of 70 m. in diameter, the ashes falling so thickly that even 24 m. from the mountain they covered the ground to a depth of 10 ft. It was estimated that the rain of dust and sand fell over an area of 270 geographical m. in diameter. Some of the finer materials thrown so high as to come within the influence of the upper air current were blown away to the e. and fell four days afterward on the island of Jamaica, 700 m. away. Bombs, slags, and lapilli may be thrown up when the volcano is comparatively quiet, but dust-showers are always discharged with violence. Thus in the constant but comparatively quiet action of Stromboli the column of the lava in the pipe may be seen rising and falling with a slow rhythmical motion. At every rise the surface of the lava swells up into blisters several feet in diameter which by and by burst with a sharp explosion that makes the walls of the crater vibrate. A cloud of steam rushes out, carrying with it hundreds of fragments of the glowing lava, sometimes to the height of a quarter of a mile. It is by the ascent of steam through the mass that a column of lava is kept boiling at the bottom of the crater, and by the explosion of successive larger bubbles of steam that the various bombs, slags, and fragments of lava are torn off and tossed into the air. It has often been noticed at Vesuvius that, after each great concussion, a huge ball-like cloud of steam rises from the crater. Doubtless it is the sudden bursting of that steam which causes the explosion. Explosions and accompanying scoriæ are abundant in Vesuvius, where the lavas are comparatively viscid; but they are almost unknown at Kilauea, where the lava is remarkably liquid.

No part of the operations of a volcano has greater significance than the ejection of such enormous quantities of fragmentary matter. In these deposits are buried trees, the bodies of animals, and the works of man. Besides the distance to which fragments may be hurled by volcanic explosion, or to which they may be diffused by the air, we have to take into account the vast spaces across which the finer dust may be borne by upper aerial currents. On several occasions ashes from Icelandic volcanoes have fallen so thickly between the Orkney and the Shetland islands that vessels there at sea have had the strange deposits shoveled off their decks. In 1783 Skaptar-Jökull ejected so much fine dust that the atmosphere of all Iceland was loaded with it for months afterward. It fell in such quantities over Caithness, a distance of 600 m., as to destroy the crops, and the period is still remembered in Scotland as "the year of

the ashie." Traces of the same deposit were observed as far as Holland. It is not therefore to be held that a volcanic deposit indicates proximity to a volcanic center, since it may have drifted from another center hundreds of miles away.

Lava streams usually consist of glass through which are diffused microlites; and well-defined crystals of leucite may be seen in specimens of Vesuvius lava which have been dipped from a white-hot stream and suddenly congealed. The green pyroxenic lava of Hawaii exhibits so extreme a degree of fluidity that, during its ebullition in pools of the crater, jets not more than a quarter of an inch in diameter are tossed up, and falling back on one another, make a column of "hardened tears of lava," while in places the jets thrown up and blown aside by the wind give rise to long threads of glass which lie thickly together like mown hay. The natives call this "Pele's hair," after one of their divinities. At its first appearance, where it issues from the mountain, the lava glows with a white heat, and flows with a motion which has been compared to that of honey or of melted iron. It soon becomes red, and, like a coal fallen from a hot fireplace, rapidly grows dull as it moves along, until it assumes a black, cindery aspect. At the same time the surface congeals, and soon becomes solid enough to support a heavy block of stone. Its aspect depends, not merely on the composition and fluidity of the lava, but on the point of egress, whether from the crater or from a fissure, on the form of the ground, the angle of slope, and the rapidity of flow. Lavas which have been kept in ebullition within the central chimney are apt to acquire a rough cellular texture. The surface of the moving stream breaks up into rough brown or black cinder-like slags, and irregular rugged cakes, which, with the onward motion, grind and grate against each other with a harsh metallic sound, sometimes rising into rugged mounds or becoming seamed with rents and gashes, at the bottom of which the red-hot glowing lava may be seen. When lava escapes from a lateral fissure it may have no scoriæ, but its surface will present froth-like, curving lines, as in the scum of a slowly flowing river, or will be arranged in curious ropy folds as the layers have successively flowed over each other and congealed. These and many other fantastic coiled shapes were exhibited by the lava which flowed from the side of Vesuvius in 1858. A large area which has been flooded with lava is perhaps the most hideous and appalling scene of desolation anywhere to be found on the surface of the globe. A lava stream at its point of escape from the side of a volcanic cone occupies a comparatively narrow breadth; but it usually spreads out as it descends, and moves more slowly. The sides of the moving mass look like huge embankments, or like some of the large mounds of "clinkers" one sees in a manufacturing district. The advancing end of the mass is often much steeper, creeping onward like a great wall or rampart, down the face of which the rough blocks of hardened lava are ever rattling. The rate of movement is regulated by the fluidity of the lava, by its volume, and by the form and inclination of the ground. Hence, as a rule, a lava-stream moves faster at first than afterward, because it has not had time to stiffen, and its slope of descent is considerably steeper than further down the mountain. One of the most fluid and swiftly-flowing lava streams ever observed on Vesuvius was thrown out Aug. 12, 1805. It is said to have rushed down a space of 3 Italian (3⅜ English) m. in the first 4 minutes, but to have widened out and moved more slowly as it descended, and finally to have reached Torre del Greco in 3 hours. A lava stream thrown out by Mauna Loa in 1852 went as fast as an ordinary stage-coach, or 15 m. in 2 hours. Long after a current has been deeply crusted over with slags and rough slabs of lava it continues to creep slowly forward for weeks or even months. The hardened crust of a lava current is a poor conductor of heat. In the case of Jorilla, a volcano in Mexico, lava was sent out in 1759, and 21 years afterward cigars could be lighted at the fissures in the deposit; after 44 years the lava still sent up steam, and after 87 years two vapory columns were still rising. No sure means have been found to ascertain the temperature of lava at the moment of discharge; but the slow rate of cooling has been regarded as of high geological significance in regard to the cooling and probable internal temperature of the globe.

Besides slags, dust, and lava, sometimes large quantities of water and mud accompany volcanic eruptions. During the eruption of Vesuvius in 1662 a torrent of water and mud poured down, overthrowing the houses and burying the inhabitants of villages. Near the foot of the mountain Roman cities were overwhelmed in the 1st century. In 1691 one of the volcanoes of Quito threw up mud and water so filled with dead fish as to cause a pestilence. Even more destructive outpourings have taken place in the volcanoes of Java, where wide tracts of luxuriant vegetation have at different times been buried under masses of dark gray mud sometimes 100 ft. thick. Mud volcanoes, perhaps not strictly volcanic, have periods of repose, when no discharge takes place, or the mud oozes tranquilly from the orifice, with shocks of activity, when large volumes of gas and sometimes columns of flame rush out with violence, throwing up mud and stones. The mud is usually cold. Among the products of such volcanoes are naphtha, inflammable gas, and sulphur. There are also many remarkable discharges of gases from the earth which seem to come from volcanic action. The most remarkable of these is in Java, known as the Valley of Death. There is a deep bosky hollow, in which from one small space on the bottom carbonic acid issues so copiously as to form the lower stratum of the atmosphere. Animals enticed by the seclusion and shelter of the spot pass in and are suffocated. This is the place that was long known as the val-

ley of the Bohon Upas, and the poison was supposed to come from a tree called by that name. Hot springs are another effect of volcanic action. They are widely distributed over the earth, but the most remarkable are in Iceland, and in Yellowstone Park, Wyoming. (See article NATIONAL PARKS.) These springs are usually intermittent in action, but explode at regular intervals, throwing up quantities of water and steam. The water usually contains silica in solution, which is deposited around the springs and forms their craters. In the Great geyser in Iceland the water is at boiling point (212°) at the surface, while a few yards below it is 266° Fahrenheit. See GEOLOGY; GEYSERS, and works referred to in the latter article. See illus., GEOLOGY, vol. VI.

VOLE, *Arvicola*, a genus of rodent quadrupeds, of a group which some naturalists constitute into a family (*arvicolidæ*), but which is more generally regarded as a tribe or sub-family of *muridæ* (q.v.). This group is characterized by a thicker and shorter form than that of the true rats and mice; an obtuse muzzle; ears of moderate size; a round and hairy tail, not so long as the body; the molar teeth with flat crowns, which present angular enameled plates. These characters exhibit an approach to the beaver family (*castoridæ*). The lemmings (q.v.) belong to this group. The species are numerous, and widely distributed, being found in Europe, Asia, Africa, and North and South America. Some of them are completely terrestrial in their habits, others are aquatic. Many are popularly called rats and mice, as the species of the genus *arvicola*, which are found in Britain. In this genus the teeth are only ten in number; two incisors and three molars in each jaw. One of the most common British species is the FIELD VOLE (*A. agrestis*), also known as the MEADOW MOUSE and SHORT-TAILED FIELD MOUSE. The whole length of the head and body is scarcely more than 4 in., that of the tail rather more than an inch and a quarter. The field vole has a large head, a very obtuse muzzle, ears just appearing above the fur, the thumb of the fore-feet rudimentary, and without a claw. The upper parts are reddish brown, the under parts ash-color, the feet and tail dusky. It burrows in the ground, or finds a retreat for itself in the excavations of some other animal, as of the mole. It chiefly inhabits low and damp situations, and dry seasons are very fatal to it. It produces from five to seven young at a birth. It is sometimes very injurious to plantations, by destroying the roots of trees and devouring their bark. Excessive numbers of this little animal were regarded in 1813 and 1814 as threatening the destruction of the forest of Dean, and the new forest in Hampshire; and many trees were killed; but a remedy was found in digging pits into which the voles fell, and from which they could not escape. The same method has been successfully employed in some of the forests of continental Europe. This species of vole is found in most parts of Europe, and in many parts of Asia. It is common in the Himalaya. — Another very common British species is the WATER VOLE (*A. amphibia*), popularly known as the WATER RAT, a much larger animal, the head and body being about 8½ in. in length, and the tail 4¾ inches. The head is thick and short, the muzzle very obtuse, the eyes small, the ears scarcely seen beyond the fur; the last joint only of the thumb of the fore-feet conspicuous beyond the skin. The fur is thick and shining, of a rich reddish brown mixed with gray above, yellowish gray beneath. Although the feet are not webbed the water vole swims extremely well, and not only at the surface of the water, but often under it. It burrows in the banks of streams, ditches, and ponds. Its food appears to consist chiefly of aquatic plants, although it objects to no kind of vegetable food, and has been known to store up potatoes in its burrow for winter. It has been supposed also to feed on worms, frogs, and small aquatic animals, and to be destructive to the spawn of fish; but this is very doubtful. This species is widely diffused over the continent of Europe. There is a black variety of it, common in some parts both of England and Scotland, which has been described as a distinct species (*A. atra*). Several species of vole are found in North America. See illus., RODENTIA, vol. XII.

VOLGA, the most important river of Russia, and the longest in Europe, has its origin in a marshy plain among the Valdai hills, in the government of Tver; lat. 57° 10′ n., long. 33° 10′ east. From its source, which is 550 ft. above ordinary sea-level, and 633 ft. above the level of the Caspian sea, into which it falls, the river flows s.e. to Zubzov, then n.e. past Tver and Koliazin to Mologa, where it turns e.s.e., and flows in that direction past Jaroslav, Kostroma, Nijni-Novgorod, and Kazan, 50 m. below which, on receiving the Kama, it turns s., passing Simbirsk, Stavropol, and Samara. Here its course again changes to s.w., and in this direction the river flows until it reaches Tzaritzin, when it bends to the s.e., and reaches the Caspian sea, which it enters by many mouths, and after a course of 2,320 miles. The Volga waters 9 governments—those of Tver, Jaroslav, Kostroma, Nijni-Novgorod, Kazan, Simbirsk, Saratov, Samara, and Astrakhan; but besides these, 12 other governments are watered by its tributaries. The course of the stream is generally divided into three parts—the upper part reaching from its source to its confluence with the Szeksna, and, though presenting many hindrances to navigation, yet capable of being traversed from Tver to Rybinsk by craft of 1½ and 2 ft. draught; the middle part, from Rybinsk in Jaroslav to Nijni-Novgorod, navigable for larger craft; and the lower Volga from Nijni-Novgorod to Astrakhan—where it is about 90 ft. deep—navigable for the largest vessels. Below Astrakhan the Volga is very much shallower —in some places only 1½ ft. deep. At Tver the breadth of the river is 720 ft.; at Mologa, 2,060 ft.; at Nijni-Novgorod, 2,069 ft., but sometimes in the spring 2½ m.

broad; at Simbirsk, about a mile broad; between Samara and Sysran, from 1 to 3 m. broad. Below Tzaritzin, at the confluence of the Sarpa, the river affords few facilities for navigation, and is remarkable for the number of branches into which it divides itself before it enters the Caspian sea. The banks of the Volga, which are elevated in the upper and middle reaches, become much lower as the river approaches its embouchure. The chief ferries and commercial towns on the Volga are: Rjev, Zubzov, Tver, Koliazin, Uglitch, Mologa, Rybinsk (the great center of the corn trade), Jaroslav, Kostroma, Nijni-Novgorod, Kazan, Simbirsk, Samara, Tzaritzin, and Astrakhan. The system of water-communication established by the Volga and its tributaries, is of the greatest importance to the commerce of Russia, connecting as it does the central districts of the country with the White sea by means of the canal of the prince of Würtemberg; with the Baltic by the three canal-systems of Tikhvinsk, Vishni-Volotchek, and Mariinsk; with the Black sea by the Upa canal, which connects with Oka and the Don; with the Caspian sea by the great stream of the Volga itself; and with Siberia by the rivers Kama and Tchussovaia. The principal affluents on the right are the Oka (q. v.) and the Sura; on the left, the Tvertza, Mologa, Szeksna, and Kama (q. v.).

VOLHY'NIA, a frontier government of west Russia, bounded on the s.w. by Galicia, and on the w. by Poland, from which it is separated by the river Bug. Area, 27,743 sq. m.; pop. '92, 2,462,069, composed of Russians, Poles, Lithuanians, Jews, Germans, and Tartars. The surface in the n. of the government is low, and plains and morasses, interspersed with forests, abound; in the s. there are hills, branches of the Carpathian mountains, but which do not rise higher than 1230 feet. Almost all the rivers flow n. and join the Pripet, an affluent of the Dnieper; a few streams, however, flow w. and join the Bug, by means of which river timber is floated down from this river to Prussia. The soil is sandy or clayey; agriculture flourishes in the s., and corn is exported to Odessa, Galicia, Poland, and partly to Great Russia. Cattle-breeding, formerly prosperous, has recently declined. Of the woods, which form the principal riches of the n. districts, fir is the chief. The mineral products include granite, lithographing stone, chalk, porcelain clay, and iron, and to some extent coal, graphite and amber. The forests abound in foxes, hares, and bears, and hunting is a favorite pastime. Many manufactories are in operation, including porcelain and machine-works, distilleries, sugar-refineries, and numerous different mills. Corn, wool, cloth, linen, timber, honey, and wax are the principal articles of trade.

VOLITION. See WILL.

VOLKSLIED. See LIED.

VOLLEY, the simultaneous discharge of a number of small arms. The same operation from cannon is called a salvo.

VOLNEY, CONSTANTIN FRANÇOIS CHASSEBŒUF, Comte de, was b. at Craon, in Anjou, on Feb. 3, 1757. He was the son of an advocate of good reputation. His family name was Chassebœuf, but on arriving at manhood he assumed the additional surname of Volney. He got his preliminary education at the colleges of Ancenis and Angers, and afterward went through a protracted course of study at the university of Paris. His father wishing him to join his own profession, he spent some time in preparing for the bar; but he renounced law for medicine, which, however, he never practiced. He had inherited a competency from his mother, and soon after completing his studies, in the year 1783, he set out for Egypt, with the intention of traveling in Egypt and Syria. This expedition occupied him about 4 years. On his return to France in 1787 he published his celebrated *Travels in Syria and Egypt*, which still contain the most trustworthy as well as one of the liveliest and most interesting accounts which have been published of the tribes with which he came in contact. This work at once procured him a great reputation. At first there was a disposition to question the veracity of some of his descriptions, but their truthfulness was fully confirmed when the French became more familiar with the Egyptians and the Arabs through the expeditition of 1796. The sagacity of the chief political conclusions to which his residence among these peoples had brought him, which in 1788 he embodied in a pamphlet—*Considerations on the War between the Turks and the Russians*—has also been shown by subsequent events. In 1790 he was elected to the etats généraux as a member for his native district, and took a somewhat prominent part in the political discussions of the years which followed, showing himself as he has done in his works a fast friend of the public liberties, a mocker at all systems of religion, and at the same time a fearless opponent of popular excesses. He was imprisoned for his outspokenness in 1793, and was not liberated till after the downfall of Robespierre in July of the following year.

In Sept., 1794, Volney published his *Ruins; Reflections upon the Revolutions of Empires*, upon which and upon his *Travels* his reputation chiefly rests. Volney believed that political, like all other organizations, are subject to decay and destruction. The discussions contained in the *Ruins* cover almost all the radical questions in politics. Its principles are those of 1789. It vindicates the doctrine of the rights of man, establishes the duty of toleration in matters of opinion, and maintains, with perhaps too much of

sarcasm and mockery, the human origin and the essential falsity of all religious systems. In the previous year Volney had published his *Natural Law*, a catechism for a French "citizen," in which he treats morality as a physical and material science, to be studied upon the same methods as the other natural sciences, and having no object but the conservation and improvement of society. This work was afterward republished under the title of the *Physical Principles of Morality*.

Toward the close of 1794 he was appointed professor of history in the short-lived ecole normale; and the brilliant discourses, not untinged with paradox, which he delivered in this capacity made a sensation in Paris even at that unsettled time. On the suppression of the ecole normale in 1795 he went to the United States, intending to spend the remainder of his days there; but circumstances made his residence there extremly disagreeable to him, and he returned to France in the spring of 1798. In his absence he had been elected a member of the institute; he was soon after his return admitted to the academy; and henceforth his life, though not inactive, was prosperous and untroubled. He had early been acquainted with Bonaparte, and had been of service to him at the time when political circumstances had deprived him of employment; and Bonaparte, on becoming first consul, desired to associate him with himself in the government as consul or as minister of the interior. Volney refused both offices, but accepted a seat in the senate. He protested against the establishment of the empire and resigned his seat in the senate; but his resignation was declined, and during the existence of the empire he formed one of the little band, sneered at by Napoleon as *idéologues*, who in the senate attempted by their criticisms to restrain the arbitrary conduct of the emperor. Henceforth, however, his occupations were mostly literary. He published *Researches into Ancient History*, several of the papers contained in which were written in the earlier part of his career; and also several linguistic works, in which he attempted to popularize, and, by means of a universal alphabet, to simplify the study of the eastern languages. He had accepted from Napoleon the title of count and the commandership of the legion of honor, and upon Napoleon's downfall he was among those who were called to the house of peers by Louis XVIII. His latest work, published in 1819, was *The History of Samuel, the Inventor of the Sacredness of Kings*. Volney died April 25, 1820, shortly after completing his 63d year.

VOLOGDA, an extensive government of Great Russia, bounded on the e. by the Ural mountains, and on the n.w. by the government of Archangel. Area, 155,498 sq. m.; pop. '92, 1,362,002, chiefly Russians, but comprising also a few Finns, by which race this territory was inhabited in early times. The districts in the e. adjoining the Ural mountains, are traversed by branches of that chain, which rise to the height of from 3000 to 4000 feet. But by far the greater part of the government is occupied by marshy plains, covered with impenetrable forests. The soil is not fertile, except in the s. districts, which are the most densely peopled, and produce corn sufficient for local consumption and the supply of the distilleries. In the middle districts, there are comparatively few inhabitants; cultivated land is rarely seen, and hemp is the only crop produced liberally. The wooded morasses of the n. are inhabited only by Finnish tribes, engaged in hunting. The majority of the people are nomadic in their habits. The banks of the rivers are, as a rule, the only inhabited places. The principal rivers are the Northern Dwina, with its great upper waters, the Suchona, Jug, and Witchegda; and the Petchora, with its affluents. Lakes are numerous. Salt-works, iron-works, and distilleries are in operation; and salt, iron, skins, tallow-candles, and cheese are exported; and corn and manufactured goods imported.

VOLOGDA, a city of Great Russia, in the s.w. angle of the government of the same name, of which it is capital, stands on both banks of the river Vologda, 260 m. (by rail) n.e. of Moscow. It is said to have been founded in the 13th c. by settlers from Novgorod, to which principality it belonged down to the 15th c., when it was annexed to Moscow. In 1553, when England opened up a trade with Russia, through the port of Archangel, Vologda was the great entrepôt for goods deported n. by the Northern Dwina; and even yet it exports to St. Petersburg and Archangel various products of its own and neighboring governments, to a considerable amount. Timber, tallow, potash, soap, candles, leather, cordage and fur are exported. Political offenders are sometimes banished to Vologda. Pop. '91, 17,825.

VOLSCI, an ancient Italian people, closely related to the Umbrians. See UMBRIA. Their territory was bounded on the w. by that of the Latini, on the n. they marched with the Æqui and Hernici, on the e. with the Samnites, and on the s. they had the sea. Along nearly the whole of their coast lay the Pontine marshes, while inland, their territory was somewhat mountainous. The Volsci were a brave and warlike people, who, frequently in alliance with the Æqui, were incessantly at war with the Romans for upward of 200 years previous to 338 B.C., about which time they appear to have been finally subdued, their territory incorporated into Latium, and they themselves created Roman citizens. See LATINI. These wars were very harassing to the Romans, as they were often carried on not so much by the Volsci as a whole, as by different cities, each frequently on its own account. Some of the chief towns, and those which took a principal part in the wars, were Antium, Velitræ, Satricum, Privernum, Ulubræ, Suessa, Pometia, Anxur, and Tarracina, and later Forum Appii and Tres Tabernæ. The legend of

Coriolanus (q.v.) is connected with the Volscian wars. See Rome, Tarquinius Superbus, Antium. From the time of their final subjugation, their history belongs to that of Rome (q.v.).

VOLSK, or Volgsk, a t. of European Russia, in the government of Saratov, on the right bank of the Volga, 80 m. n.e. of Saratov. Fat and skins are prepared and exported to St. Petersburg, and corn is exported in large quantities to Astrakhan and Rybinsk. The inhabitants are chiefly engaged in agriculture. Pop. 1889, 38,550.

VOLT. See Volta: Electricity.

VOLTA, Alessandro, a celebrated Italian physicist, was born at Como, of a noble family, in 1745, and received an excellent education. In 1774, he was appointed professor of natural philosophy at Pavia, and continued to discharge the duties of this chair till 1804, when he retired to his native town, to spend the rest of his days. Volta, while but a youth, had exhibited considerable taste for letters, and had even written two poems, one in Italian, and the other in Latin; but as he grew older, he abandoned all such pursuits, and devoted himself exclusively to the sciences, especially those connected with electricity. At intervals between 1777 and 1782, he visited Switzerland, Tuscany, Germany, Holland, France, and England, making the acquaintance of the most eminent philosophers of these countries; and on his return is said to have introduced the culture of the potato into Lombardy. In 1796, he was one of a deputation sent to solicit the forbearance of Napoleon; and was received with distinction by the French general, who afterward invited him to Paris, to exhibit, to the members of the Institute, the action of the "pile" (see Galvanism), which he had invented, enrolled him in the legion of honor, and conferred on him the order of the iron crown, with the titles of count and senator of the kingdom of Italy. He was also elected (1801) a foreign associate of the French institute, ten years after he had been made a fellow of the royal society of London. He died at Como, Mar. 5, 1827. Volta's contributions to the science of electricity are of great importance, the chief of them being his theory, in opposition to the "animal-electricity" doctrine of Galvani, that the electric power resides in the metals; although, in turn, he fell into the error of supposing that the chemical action of the different kinds of metal on each other was only incidental. He also invented an electric battery, consisting of a series of cups arranged in a circle, each cup containing a saline solution in which were immersed, edgewise, two plates, one of zinc and the other of silver, the zinc plate in one cup being connected with the silver one in the next by means of a wire. This battery was, however, soon after superseded by his "pile." He also invented, in 1775, the *Electrophorus* (q.v.); in 1782, the electrical *Condenser* (q.v.), employing with it an electrometer (see Electricity), in which two straws were employed instead of the gold-leaf strips now in use; and also (1777) the hydrogen-lamp, and the electrical pistol. Most of his important discoveries were communicated by him directly to the royal society (published in the *Philosophical Transactions* of 1782,1783,1800). A collection of V.'s works, in five vols., was published, in 1816, at Florence. After him Galvanism (q.v.) is often called *Voltaic Electricity;* and the practical unit of electro-magnetic force is called a *volt.*

VOLTAIRE (François Marie Arouet, his true name)—one of the most famous of French writers—was b. according to his own accounts, as given in later life, on Feb. 20, 1694, at Chatenay, near Sceaux. The register of his baptism, however, assigns Paris as the place of his birth, and dates it Nov. 21 of that year. As to which of these statements may be really the correct one, his biographers are not yet fully agreed. His father was François Arouet, a notary of the Châtelet, ultimately treasurer of the chamber of accounts; his mother, Marguerite D'Aumar, of a noble family of Poitou. Of two sons born to them, François was the younger. He received his education at the college of Louis le Grand in Paris; and on completion, he was set to study law by his father. But he found this pursuit too disgusting, and speedily quitted it for the career of a man of letters. By his godfather, the abbé de Châteauneuf, who was very intimate with her, he was introduced to the celebrated Ninon de l'Enclos, and through her to the best French society of the period. In these wicked and witty circles, being himself deficient in neither wickedness nor wit, the young man prospered extremely: and so perfectly unexceptionable was the company in which he found himself, that one day he could exclaim, looking round the table with complacency: "Are we all, then, either princes or poets?" His father, however, deeply disapproving of the life he led as immoral, and probably not inexpensive, had him sent to Holland with an embassy. Here he became involved in a love-affair of the more respectable kind, which ended, not in marriage, as he seems to have proposed, but in his being sent back to Paris, to resume his gay career. Shortly, it suffered another interruption: on suspicion (unfounded) of his being the author of some satirical verses, reflecting on the government of Louis XIV., then just dead, he was sent to the Bastille (May 17, 1717), where he remained upward of a year. This time of imprisonment he improved by sketching his famous poem, afterward published as the *Henriade*, and by finishing his tragedy, *Œdipe*, which was produced on Nov. 18, 1718, and had so great a success with the public, as not only to delight the author, but somewhat to mollify his old parent, who began to surmise

that the despised "poetry" of his offspring was not unlikely to come to something. The same success did not, however, attend his next ventures: his tragedy, *Artemire*, produced in 1720, was hissed off the stage; and his *Mariane*, which followed in 1724, fared but little better. Meantime he had again visited Holland, making, on the way, the acquaintance of Jean Baptiste Rousseau, a poet of some importance, then living at Brussels. The two geniuses met as friends, only to part as irreconcilable enemies. Their quarrel is said to have originated in a characteristic *mot* of Voltaire, who, his critical opinion being asked of an *Ode à la Postérité*, which Rousseau read to him, had the candor to reply thus: "Mon ami, voilà une lettre qui n'arrivera jamais à son adresse." In the summer of 1725 occurred a misadventure, which, for Voltaire, had important consequences. At the dinner-table of the duke de Sulli, he resented with spirit an affront put upon him by the chevalier de Rohan, who, worsted in the war of wit, as most men were likely to find themselves with Voltaire, avenged himself some days after by having his adversary thrashed in public by footmen. Subjected to so gross an outrage, Voltaire retired for a time into private life, assiduously perfected himself in the small-sword exercise, and then courteously entreated the chevalier to a meeting in the *duello*. The chevalier, as it proved, had small stomach for the encounter; having immortalized himself sufficiently by his insult to the poet, he considered it unnecessary to aspire to the further immortality of being killed by him. Under superficial pretenses of accepting the challenge, his practical answer to it came in the form of a *lettre de cachet*, which consigned Voltaire once more to the Bastille. His imprisonment was not on this occasion a long one; but it was only under sentence of exile that he was permitted to issue from durance; and on doing so, he betook himself to England. Some little time previous, the young Arouet had assumed the name of Voltaire, destined to become so famous. As to the origin of this name, considerable perplexity has existed; but there can scarce be a doubt of the correctness of the conjecture thrown out by Mr. Carlyle, in the second volume of his *Frederick*, that it is simply an anagram of Arouet l.j. (*le jeune*).

Arriving in England in 1726, Voltaire remained there upward of two years. Of this episode of his life, we have only the most meager account. It is certain, in a general way, that he had the *entrée* to the best English society; he knew Bolingbroke, Pope, and we need not doubt, many others of the intellectually distinguished. Of his visit to the famous Mr. Congreve, and the little skirmish of wit between them, we have express record. It was a whim of Congreve to affect dislike of his fame as an author, as to a certain extent a disparagement of his claims as a person of quality. On his signifying to Voltaire that it was simply as this last he desired that his friends should regard him, he was answered to the effect, that had he been nothing more than the elegant gentleman he considered himself, M. de Voltaire would scarce have thought it worth while to solicit the honor of his acquaintance. To Voltaire, his residence in England was fruitful of new knowledge and ideas; in the school of the English deists, Bolingbroke, Collins, Tindal, Wollaston, etc., he found speculations much to his mind; the philosophies of Newton and Locke he studied diligently; and in his subsequent dramas there may be traced a distinct influence from Shakespeare, whom, however, he has expressly vilified as a barbarous monster of a writer, intolerable to any reader with the least tincture of orthodox French *goût* in him. Not the less the distinction remains with Voltaire of having been the first Frenchman to recognize in some decisive, if grudging and inadequate way, the essential superiority of our great national poet. The intellectual debt thus indicated was not the only one which Voltaire owed to England. While resident there, he published in a revised form his epic poem, the *Henriade*, a surreptitious edition of which had already appeared in France. The work was dedicated in English to queen Caroline; the subscription for it was headed by her and other members of the royal family; the rank and fashion of the country could not but follow the illustrious example set them; and for result Voltaire could convey into his pocket the comfortable sum (stated so high as $40,000), which became the basis of his future fortune. From the time of his return to Paris in 1728, he had always on hand some speculation: investments in corn, bacon, or whatever a pretty penny could be turned by, with now and then a fat army-contract, which a friend might have interest to secure for him; and so shrewd in his finance was he, that, owing but little to his books, which, despite of their immense popularity, were never a source of great profit to him, his income at his death is ascertained to have netted some $35,000 per annum, a revenue then to be styled princely. Of his literary labors, from this time forward unremitting, the sum of which remains in something like ninety volumes, no detailed account can here be attempted. His was truly a universal genius; he wrote literally everything—histories, dramas, poems, disquisitions, literary, philosophical, and scientific; novels, for the most part with some doctrinal purpose, of which his famous *Candide, or the Optimist*, may stand as the type; his literary correspondence was on an unexampled scale; and he was seldom without some fierce polemic on hand, in which his adversaries had to writhe for the amusement of the public, under the scourge of his envenomed wit.

In the gay society of Paris, he became acquainted with a certain Mme. du Châtelet, who was living apart from her husband, the marquis, though still on polite terms with him. She was *assez spirituelle;* a most fascinating woman of the world, and in the mat-

ter of intellectual accomplishment, the bluest wonder of the period; most especially she was deep in mathematics, and had mastered the mysteries of Newton's *Principia*. As himself an admirer of Newton, Voltaire could not but be charmed to meet him thus surprisingly put into petticoats; nor could a woman so intellectual as madame fail, in her turn, to appreciate the tender attentions of such a genius as M. de Voltaire. Their intimacy became extreme; and finally, in 1733—the husband of the lady behaving like a philosopher and man of fashion of the time, and continuing now and then to visit them—they went off to prosecute it undisturbed at Cirey, an old château in Champagne, the property of M. du Châtelet Here, for the most part, they diligently studied Newton together for the next fifteen years. The arrangement seems to have been on the whole a not unhappy one; but toward the close it became complicated for M. de Voltaire by the advent of another lover, in the person of a Monsieur de Saint-Lambert. It is not conjectured that this gentleman knew anything of Newton, or was at all such a genius as Voltaire; but it is certain that, on some other ground unexplained, he found favor with Mme. du Châtelet. The philosophy which the husband had been good enough to practice in favor of Voltaire was now required of himself; and after a little unpleasantness he was able to reconcile himself to the inevitable. This curious triangular love-affair—or *square*, if we include the husband—was not, however, of very long duration. In 1748 Mme. du Châtelet died in child-bed. Voltaire was overcome with grief; and the touching reproach which, in the first agony of bereavement, he addressed to the culpable M. de Saint-Lambert, a fortunate chance has preserved for us: "*Eh! mon Dieu! Monsieur, de quoi vous avisiez vous de lui faire un enfant.*" This, which is now so shocking, illustrates strikingly the morals of a period in which it seemed entirely *comme il faut*.

To dissipate the sense of loneliness which overpowered him in the loss of his "divine Emilie," as he was wont, in his more lyrical moments, to call her, Voltaire once more betook himself to Paris, whence, in 1750, he proceeded to Berlin, on the invitation of the young king of Prussia, Frederick, since known as "the great." Between him and Voltaire much correspondence had already passed; and they seem to have entertained for each other a sincere admiration and regard. When they came together, however, it was found, as so often in such cases before and since, that it is not in the matter of mountains only that "distance lends enchantment to the view." They quarreled bitterly, and parted; Voltaire, at his exit from the country, being subjected to indignities which he found it hard to forgive. Into the details of the quarrel we need not enter. When we say that the king was a poet at once most profuse and most execrable; and that the main function of Voltaire—himself a poet—was to criticise and correct his verses, it should almost seem that we indicate, without going further, a sufficient *origo mali*. Voltaire detested the king's verses; the king could hardly have been even the very bad poet he was, without heartily detesting Voltaire's criticism and corrections. Is it marvelous that in no long time they got heartily to detest each other? A reconciliation was afterward effected, and their literary correspondence was resumed under the old forms of friendliness; but meantime Voltaire had avenged himself in the amusing but most scandalous chronicle, entitled *Vie Privée du Roi de Prusse*, which was found at his death among his papers, and published, as there is pretty good reason to suppose the wicked wit meant it should be.

After some years of a somewhat unsettled kind, Voltaire, in 1758, established himself along with his niece, Mme. Denis, at Ferney in Switzerland, where, with little exception, the last 20 years of his life were passed. During this period some generous traits of character are recorded of him. Thus, he rescued from extreme want a grandniece of Corneille the great dramatist, had her carefully educated under his own eye at Ferney, and made over to her the proceeds of an annotated edition of her ancestor's works, which he issued for her express benefit. His noble exertions in behalf of the Calas family, the victims of a shameful persecution, are also well known. In 1778 he was induced by his niece to revisit Paris. By the Parisians the poet, now in his 84th year, was received with a perfect tumult of enthusiasm, the excitement connected with which is thought to have hastened his death, which took place on May 30 of that year.

With the doubtful exception of Rousseau (Jean Jacques), who in his character of *vates* and enthusiast, was perhaps even more deeply influential, Voltaire is by far the most memorable of the band of celebrated writers whose crusade against established opinions was preparing the grand *culbute* of the French revolution. As every one knows, it was mainly in the field of religious polemic that his destructive energies were exerted. It is common to stigmatize him as an atheist, but this is simply to exhibit ignorance. Discarding revelation, he steadily upheld the truths of natural religion, and was, in fact, a deist pretty much of the English type. As such, he was not a little despised by the more "advanced" minds of the period, Diderot and the like, who considered belief in a God clear evidence of intellectual infirmity. His favorite weapon was ridicule, and there was never, perhaps, a greater master of it. In a particular form of polished mockery, Voltaire remains almost without a rival. His prose is the perfection of French style; it is admirable in grace, clearness, vivacity, and alive like a sparkling wine with the particular quality of *esprit* peculiar to the people and the language. As a dramatist Voltaire takes rank as a worthy third with his two great prede-

cessors, Corneille and Racine. His most famous poems are the *Henriade*, before mentioned, the one epic of the language, and *La Pucelle*, which is, perhaps, more properly to be styled infamous, such is the profanity and indecency with which the writer has willfully defiled the heroic story of the maid of Orleans. In the historical works of Voltaire, with the utmost lucidity of method, there are traces of a more philosophical treatment than had previously been applied to such subjects. For its narrative charm, his little historiette, *Charles Douze*, familiar to every school-boy, is in its kind a perfect model. In English, biographical works on Voltaire are very few in number. Of his earlier life, a most racy and amusing sketch will be found in the second volume of Mr. Carlyle's *Frederick the Great;* and his relations with Frederick are of course in that work treated of in full, with the writer's characteristic humor and insight. As a critical estimate at once of the man and of the writer, nothing better can anywhere be found than Mr. Carlyle's earlier essay.

In 1866 the first volume of a *Life and Times of François-Marie Arouet, calling himself Voltaire*, by Francis Espinasse, was published by Chapman and Hall; but this work, which promised to ably supply a desideratum, has been left unfinished. See also *Voltaire*, by David Friedrich Strauss (1870); *Voltaire*, by John Morley (London, 1872); and *Voltaire et la Société du XVIII^e Siècle*, by T. G. Desnoiresterres (8 vols. 1855–76). The *Life* by Parton (1881) contains a mass of facts, but is poor in criticism.

VOLTERRA, a t. of central Italy, in the province of Pisa, stands on a table-land at the height of about 1800 ft. above sea-level, 30 m. s.e. of Leghorn. It is surrounded by cyclopean walls, which are in a better state of preservation than any structures of the same kind in Italy. The gate called *l' Arco*, and the remains of baths and of an amphitheater, are interesting vestiges of antiquity; the cathedral, the *Museo Nazionale* in the *Palazzo Tagaia* has fine collections. Volterra contains a college, numerous schools, and a library of 120,000 volumes. Wine, oil, corn, and mulberry-trees are grown in the lands belonging to the town, which also possesses considerable mineral wealth. The salt works supply all Tuscany with salt. Pop. '81, 5347.

Volterra, the ancient *Volaterræ*, was one of the most powerful and important of all the Etruscan cities, and came into the possession of Rome 474 B.C.; after the fall of the empire, it suffered much from the invasion of barbarians.

VOLTERRA, Daniele da, 1509–66, b. Tuscany, studied art in Volterra, Siena, and Rome. In the frescoing of the Vatican he assisted Del Vaga, his former teacher, was an associate of Michael Angelo and was nick-named the "breeches maker" for having clothed some of the latter's nude figures in the "Last Judgment" by order of Paul IV. His best works were the "Descent from the Cross," in the church of Trinita de'Monti, and the "Massacre of the Innocents," in Florence.

VOLTIGEURS, picked companies of irregular riflemen in the French regiments. They are selected for courage, great activity, and small stature. It is their privilege to lead the attack.

VOLTI SUBITO (Ital. turn quickly), in music, an indication placed at the foot of a page, to signify that the page ought to be turned without delay.

VOLTRI, a t. of northern Italy, in the province of Genoa, and 9 m. w. of the city of that name, on the gulf of Genoa. Its churches are richly adorned; it contains many fine villas, and manufactures paper extensively. Near it are the sulphureous springs and baths of Aqua Santa, very efficacious in cases of cutaneous disease. Pop. 6,000.

VOLTUMNA, the goddess of the Etruscan confederation. The deputies from the 12 divisions met at her temple, whose site is uncertain, and is placed by some at Monte Fiascone, and by others at Viterbo.

VOLTURNO, a river in s. Italy, rising in Monte Santa Croce, flowing s.e., and w., and emptying after a course of about 100 m. into the gulf of Gaëta. It is the ancient Vulturnus. Garibaldi fought the Neapolitan royal army on its banks in the autumn of 1866.

VOLUMET'RIC ANALYSIS, in chemistry, consists in submitting the substance to be estimated to certain characteristic reactions, the chemist employing for such reactions liquids of known strength, and from the quantity of liquid employed to induce the reaction, determining the weight of the substance to be estimated by means of the laws of equivalence. The idea of this method first suggested itself to Gay-Lussac in considering how most readily to determine the amount of silver in an alloy of that metal and copper; but the method itself did not come into general use till within the last 30 years. The liquid reagents of known strength are called *standard solutions;* and the amount employed may be estimated either by weight or by volume, but the latter, being the easiest of application, is universally employed; and hence this method of analysis, based on the use of standard solutions, is called *volumetric analysis.* In order that a reaction may be applicable in volumetric analysis it must satisfy the two following conditions: (1) It must not occupy much time; and (2) the termination of the reaction must be

easily recognized and unmistakable to the eye. The necessity that these conditions should be fulfilled, very much limits the the number of volumetric processes. In addition to the ordinary chemical apparatus, this kind of analysis requires graduated glass vessels of different kinds for the measurement of the standard solutions. Of these, the most essential are: (1) *Pipettes*, which are glass vessels of the form of figs. 1 and 2, intended for the delivery of the standard solution. Fig. 1 is provided with a single mark upon the neck, while fig. 2 is divided and graduated through its whole length, the division being always made into cubic centimeters (c. c.), according to French scale; (2) *Flasks* graduated for the contents in various sizes from one-tenth of a liter to five liters, and used for the preparation of standard solutions; (3) *Burettes*, or graduated tubes for measuring the liquids used in an analysis. The burette was invented by Gay-Lussac; but since his time, various modifications have been proposed, the best of which, for general purposes, is that which is known as Mohr's burette. It is shown in fig. 3; and to its lower part is attached an india-rubber tube and spring-clamp or clip (*quetsch-hahn*). Its principal advantages over other forms of the instrument are, that its constant upright position enables the operator at once to read off the number of degrees of standard (or test) solution used for any analysis, while the quantity of fluid to be delivered can be most accurately regulated by the pressure of the thumb and finger on the clamp; moreover, as it is not held in the hand, no error is likely to arise in the measurement from the heat of the operator's hand. The greatest drawback to it is that it cannot be used for those test solutions which decompose india-rubber.

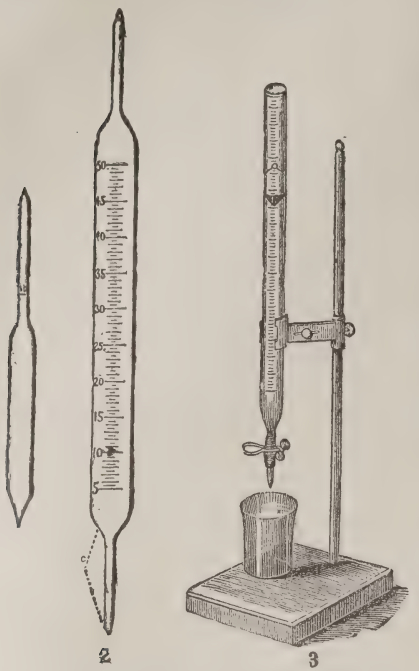

FIG. 1.—A pipette, containing 10 c. c.
FIG. 2.—A pipette, containing 50 c. c., divided through its whole length in c. c.; being thus graduated for measuring the delivery of fluids.
FIG. 3.—*a*, the india-rubber; *b*, the slips made of brass wire, by which the india-rubber tube can be closed at will.

The *standard solutions*, known also as *test* or *titrated solutions* (from the French word *titre*, which signifies the standard of a coin), may be divided into (1) such as are immediately prepared by weighing a substance of known composition, dissolving it, and diluting it to the required volume; and (2) such as are prepared by approximate mixture and subsequent exact analysis. The preparation of the first kind requires no description; for the preparation of the second kind, we must refer to the article ANALYSIS, VOLUMETRIC," in Watts's *Dictionary of Chemistry*, vol. 1. p. 259, where the method is fully explained, and as an example, the preparation of a standard solution of sulphuric acid containing *t* grammes of hydrated sulphuric acid in 1 liter is given. It is obviously essential that the greatest care must be taken both with respect to the graduation of the measuring instruments and the strength and purity of the standard solutions, which must be protected from evaporation and other hurtful influences by being kept in bottles of 1 or 2 liters' capacity, provided with well-ground stoppers.

Volumetric methods are usually classified as follows, according to the principles on which they are based—(1) *Analysis by saturation*, when the quantity of a base or an acid is measured by the quantity of acid or base which is required for exact saturation—a point to be determined by test-papers, tincture of litmus, etc. (2) *Analysis by oxidation and reduction*, when the quantity of the substance to be determined is found by the quantity of chlorine, bromine, iodine, or oxygen to which it is equivalent (regarded as oxidant), or by the quantity of chlorine, bromine, iodine, or oxygen which it requires to pass from a lower to a higher stage of oxidation. The chief oxidizing agents are permanganate of potash and bichromate of potash; while the reducing agents chiefly used are protoxide of iron and hyposulphite of soda. (3) *Analysis by precipitation*, when the determination of a substance is effected by precipitating it in some insoluble and definite combination. Our limited space does not admit of our giving an example of more than one of these forms of analysis, and from its historic interest we shall select the last, in its application to the determination of silver. We shall borrow Mr. Sutton's account of this process. "Suppose," he observes, "that it is desirable to know the quantity of pure silver contained in a shilling. The coin is first dissolved in nitric acid, by which means a bluish solution containing silver, copper, and probably other metals, is obtained. It is a known fact that chlorine combines with silver in the presence of other metals to

form chloride of silver, which is insoluble in nitric acid. The proportions in which the combination takes place are 35.5 of chlorine to every 108 of silver; consequently, if a standard solution of pure chloride of sodium is prepared by dissolving 58.5 grains of the salt—i.e., 1 eq. sodium (= 23) *plus* 1 eq. chlorine (= 35.5) or 1 eq. chloride of sodium—in so much distilled water as will exactly make up 1000 grains by measure, every single grain of this solution will combine with 0.1080 of a grain of pure silver to form chloride of silver, which precipitates to the bottom of the vessel in which the mixture is made. In the process of adding the salt solution to the silver, drop by drop, a point is at last reached when the precipitate ceases to form. Here the process must stop. On looking carefully at the graduated vessel from which the standard solution has been used, the operator sees at once the number of grains that have been necessary to produce the complete decomposition. For example, suppose the quantity used was 520 grains; all that is necessary to be done is to multiply 0.1080 grains by 520, which shows the amount of pure silver present to be 56.16 grains." By volumetric as compared with ordinary analysis, a large amount of time, labor, and therefore of expense, is saved; at the loss, however, often of due accuracy, unless the greatest care be taken that the standard solutions are of due strength, and the instruments accurately graduated. An analysis can thus be completed in a quarter of an hour that would formerly have occupied a day or more. Independently of its application to pure chemistry, it facilitates to a great extent the chemical analysis of urine (on which subject see the English translation of Neubauer and Vogel *On the Urine*, published by the New Syd. Soc.), of waters (on which see Parkes *On Hygiene*), of manures, soils, etc.; and its processes have been freely introduced in the British Pharmacopœia. The standard book on this subject is that of Mohr, a German chemist; the English reader may consult the text-books of Scott of Dublin, and Sutton of Norwich, and various memoirs in the *Chemical News*.

VOLUNTARY CONVEYANCE is, in bankruptcy and other proceedings, a conveyance which is made without any legal consideration, either of money or of marriage; and in competition with creditors having deeds made for consideration, is often deemed fraudulent, and is generally postponed or set aside altogether.

By an early statute (27 Eliz.) there is a presumption of fraud in cases of voluntary conveyance, but this may be repelled by evidence that there was reciprocity of benefits, and that the transaction was *bona fide* and not intended to deceive a subsequent purchaser. The statute alluded to, from its date, forms part of the common law of the United States, and has not been materially altered by state laws. It is held that such a conveyance is good as between the parties to it; and a distinction is made between prior and subsequent creditors, the former deriving no benefit from the statute. As to goods and chattels, the law was established by 3 Henry VII. and 13 Eliz. c. 5, which declare such conveyances, if made with intent to delay, hinder, and defraud creditors, void as against the person to whom such frauds would be prejudicial.

VOLUNTARYISM, the principles or system of polity distinctive of those who advocate the separation of church and state; the cessation of state endowments and state grants for religious purposes, and, in general, of all interference, patronage, or exercise of authority on the part of the civil power in the religious and ecclesiastical affairs of the subject. The terms Voluntaryism and Voluntary have been in use since the date of the keen discussions regarding civil establishments of religion—commonly called the "Voluntary controversy"—which sprung up in the second decade of this century between churchmen and dissenters, in Scotland; and they serve to suggest, not inappositely, the fundamental conception which underlies the creed of religious dissent, that all true worship, or acceptable service in religion, must be the free expression of individual minds, and that, therefore, religion ought to be left by civil society to mold itself spontaneously according to its own institutions and spiritual nature, without violence to individual freedom from any interposition of secular authority or compulsory influence. Voluntaryism seeks to define more accurately the limits of civil power by defining more adequately than preceding theories had done the latitude due to the movements of religion. Assigning the magistrate his proper sphere, it is equally careful to assign the church and the individual their appropriate spheres of responsibility and duty in reference to religion, within which they may work unchecked, in full harmony with all the claims of civil order. Voluntaryism may be regarded as the formula of advanced Protestantism, the corrected doctrine of church and state, which the failure of the experiment of national churches has forced on public thought. It is a protest in modern language against the encroachment of the temporal power, whether under the name of magistrate, nation, or political majority, on the rights and liberties of individual conscience. Voluntaryism has sometimes been erroneously considered the offspring of theological neutrality. On the contrary, its leading advocates base it on the expressed law of Christ respecting the constitution, administration, support, and extension of the church, as well as on the rights of conscience, the nature of civil government, and considerations of general equity and policy. In its most extensive sense, Voluntaryism embraces the whole question of the province of the magistrate in reference to religion and the church. Voluntaries admit that magistrates as well as other men, being under law to God, ought

so to execute the proper duties of their office that all shall be done in consistency with the paramount claims of morality and religion. At the same time, the nature and design of civil government excludes their authority from the domain of religion and conscience, and confines it to the secular concerns of individuals and of society. Magistrates, like other men, are under obligation to seek and to follow the highest available light and guidance in duty; but it is not therefore allowed them to convert the rules of the Divine Word, which are addressed exclusively to the individual conscience, into laws for civil society. God alone being lord of the conscience, such laws only—though revealed in his Word—may be adopted and enforced in civil society as are requisite for its outward preservation, peace, and good order, and for the advancement of those secular interests which are the proper care of its rulers. While, therefore, magistrates, no less than other men—and for reasons common to all favored with the Gospel ought, as individuals, to embrace and profess the Christian religion, and to employ wisely and justly the influence arising from their circumstances and station, it is no part of their political or official duty, or of the homage required of them by Christ, to emit, adopt, prescribe, or enforce a confession of faith; neither is it within their province to aim at establishing or propagating Christianity by the civil arm, to provide for, endow, or subsidize its teachers either in churches or schools; but it is their duty impartially to protect all their subjects, of whatever creed, in the enjoyment of full religious liberty, so long as their manner of exercising this civil right does not infringe on the equal rights of others. On this ground, and with such qualification, it is their duty to abstain from all interference with the jurisdiction and economy of the church—not excepting the matter of its support—which being regulated, as Voluntaries believe, by special ordinances of Jesus Christ, its head, it is an invasion of his prerogatives, and a frustration of his law for its support and extension, to place, or suffer to be placed, on the footing of a civil establishment. The doctrine regarding the support of religion has always been an important article in the Voluntary creed, and, in a restricted sense, Voluntaryism has been popularly defined by this doctrine. Negatively, the duty of providing for the support of Christian institutions does not lie with the magistrate or nation. The giving of property for the support of the gospel has been elevated by Voluntaryism from the position of an almost eleemosynary and political custom, to the rank of a systematic obligation and a financial law of the church. It is recognized as an act of religion, the duty and privilege of all Christians; and as each man is a steward of his silver or gold, responsible to none but its great owner for his disposal of it in religious matters, the magistrate can possess no right to demand from him any portion for religious uses, or to apply to these uses the proceeds of taxation imposed for general ends. Civil society being promiscuous and variable in its constituents, a fixed arrangement for the endowment of religious bodies out of the public funds is a fixed usurpation—as a system of occasional grants is an occasional usurpation—upon the liberty and property of all who dissent. The existence of an absolute unanimity among the subjects—even were it possible, as it would be otherwise, to ascertain and secure it from time to time—however it might remove for the moment from any minds the feeling of political grievance incident to such arrangements, could neither justify them as a policy, nor alter their character as an interference with religion in its economics. In its broad aspect, as an overstepping of the sphere of magistracy, all who restrict the magistrate, on whatever specific grounds, to secular affairs, must deem such interference objectionable; and Christian Voluntaries would reasonably ask, why legal machinery should be employed to gather the offerings which, in the state of public sentiment supposed, must be flowing unforced through their natural channnls? and in particular, whether, if Christ has not appointed the magistrate to "tithe and toll" for his church, society can presume to assign him a work beyond his province? There is a manifest division of duties dictated alike by reason and revelation; and Voluntaryism claims the results of experience as proof of the entire want of adaptation in the compulsory or magistratical power to deal with the support of a living religion. To burden the rent-roll, increase the assessments, distrain the goods and chattels of citizens, or even to preserve the forms of legal exaction for such a purpose, are measures which it is hard to believe either politic, scriptural, or just. The pecuniary supplies required for religious objects are to be secured, according to Voluntaryism, solely through the operation of moral influences and sacred motives. Truth, as well as error, must be left to provide for itself. The responsibility and privilege of providing for the support of Christianity having been attached by Christ to his church, it is further his law that its institutions shall be maintained and extended by the voluntary liberality of its friends. A primary obligation rests on those enjoying the services of a pastor to provide according to their ability for his maintenance, on the apostolic principle—"let him that is taught in the word communicate to him that teacheth in all good things;" while, on the equally apostolic principles, that the laborer is worthy of his hire, and that the strong should aid the weak, a mutual and collective responsibility remains with the general membership, to supply each other's ecclesiastical necessities, and to unite in measures that may provide an adequate remuneration to the pastors or other ministers of the church. Civil establishments of religion, together with all forms of state endowments and grants for religious purposes, are thus condemned by Voluntaries as human expedients, adverse to Christian development and the working of the law of self-support, which alone draws forth the resources, and edu-

cates the consciences and habits of the people. Inadmissible, as introducing the compulsory element into the free and delicate movements of Christian society, and intruding magistracy into a sphere which the history of all struggles for the higher liberty teaches must be preserved to the individual and the church, these institutions tend to foster political dependence and class-feeling among the recipient bodies, and prevent those relations of honorable trust and responsibility which best unite pastors and people. These views express what may be called ecclesiastical Voluntaryism. On the question of education, various shades of opinion exist among Voluntaries. All are agreed that the religious education of the young belongs to the parent and the church, and is not to be provided or superintended by the state. How to secure this principle in connection with a system of national schools or government grants for education, continues to be the problem of Voluntaries. Some seek the solution in a plan of local boards representing the parentage and community, who shall manage the schools, and decide the character of the teaching; and of these, some advocate separation of the hours for religious and secular lessons. Others, who think that while by these methods state superintendence may be avoided, state aid is yet directly or indirectly received for religious instruction, would accept a system which provided simply for schooling in secular or common branches. Those known as Voluntary educationists reject the idea of any national system, some on account of the religious difficulty, and others on grounds connected with the philosophy of education and the theory of government. Voluntary educationists would leave the education of the poor to be secured by the operation of those influences which originate and sustain other necessary and benevolent measures. The education of the children of classes not necessitous they expect to flow from private enterprise and free association. Voluntaries consistently object to grants to denominational schools dependent on the condition of teaching religion, to grants to ragged schools and all semi-religious institutions, as well as to the appointment and payment by the state of chaplains for prisons, the army, etc. In reference to the Sabbath, holding the sacred character of the day, some Voluntaries appear to admit that the magistrate is both entitled and bound not only to make it a *dies non* in his own department, but also to prohibit labor and amusements throughout the nation. Others, equally holding the morality of the day, with more regard to strict theory, deny him the power of inflicting pains and penalties, however mild, in a matter radically religious, at the same time that they assert the obligation of the state to secure all its members due protection and facility in the practice of their worship, and to make such laws for this end as may be fit, in view of prevailing religious observances. Regarding national fasts and thanksgivings, most Voluntaries hold that the style of authority in which royal proclamations appointing these have usually been expressed is objectionable, as assuming a right to prescribe the topics and language of devotion, and to regulate its seasons, and insist that the language of invitation should be substituted for that of command. Some, while ready to comply with an invitation of the sovereign to join in an offering of prayer on occasions they judge suitable, do not allow that it forms any part of magisterial duty to issue such appeals, or that the royal act imparts a national character to the service. Ordinary political acts become national when done by the proper national organs; but no religious acts can acquire a national character except they are participated by the body of the people. When this is the case, the exercise is national, though not evoked by the call of the chief of the state, and it is not made more national by that call. The advantage of simultaneousness and unity is attainable on the widest scale by the natural concert of churches apart from royal initiative, which, if it may be followed when right, need not be waited for as indispensable to true national worship. On the question of marriage, Voluntaryism, recognizing its character as a civil transaction, demands that all religious parties stand on the same level in regard to it. Withholding legal sanction from all immoral connections, and punishiug breaches of the lawful contract, magistrates are not warranted to visit with penalties any mere departure from the standard prescribed to Christian conscience, or embodied in ecclesiastical law. Political Voluntaryism, as it is sometimes called, is simply Voluntaryism expressed in the language of the politician—the doctrine of the entire religious equality of all citizens in the eye of law, stated and defended without reference to specific religious opinions, and in the way of appeal to principles generally received.

VOLUNTEERS—the great defensive citizen-force of Great Britain, in some degree corresponding to the national guard of continental states. It is essentially self-supporting, and wholly unpaid; although government arms the men, and contributes a certain sum toward the corporate expenditure. The oldest volunteer corps is the "honorable artillery company" of the city of London, which dates from the reign of Henry VII.; although still called artillery, it comprises artillery, cavalry, and infantry, and is probably the oldest armed body in Europe.

The volunteer force of Great Britain is now a form of militia, and owes its origin to the feeling of alarm which in 1859 pervaded England by reason of the alleged unfriendly designs upon that country of Napoleon III. Since then the volunteer forces have been organized by the government, which provides adjutants, drill-masters, and a staff of inspectors. The force cannot be used in times of civil disturbance, but only in case of actual or threatened invasion. In 1891 the volunteer force numbered 260,627 men. See Militia.

The American Congress, by an act passed 1792, recognized the existence, in many of the states, of volunteer organizations not included in the militia of those states; and it has since, from time to time, raised volunteers for temporary purposes. Such troops were U. S., rather than state forces; their officers were appointed by the president. In the Mexican war the volunteer forces amounted to some 30,000. In the late civil war, congress, by an act passed 1861, authorized the president to accept volunteers to a number not exceeding 500,000, whose time of service was to be fixed by the pres. at not less than six months, nor more than three years, and who were to be disbanded at the end of the war. The call was to be equalized among the different states; the governors of each of the states had to commission the officers. These troops were subject to all the rules and regulations of the U. S. army. Again, in 1862, the pres. was authorized to make a call for volunteers, at the same time offering a bounty; and it was by this method and by enforced drafts that the army was raised. The power of raising armies vested in congress by the constitution enables it to place a large volunteer force in the field, should occasion arise. At the end of the period for which the men have been enlisted, they are mustered out of the service.

VOLU'SIA, a co. in e. Florida, having the Atlantic ocean for its e. boundary; organized 1825 as Mosquito co. and subsequently as Orange; 1288 sq.m.; pop. '90, 8467. Soil productive for oranges and other fruits. Co. seat, Deland.

VOLUTE, in architecture, the spiral ornaments of the Ionic and Corinthian capitals, probably derived from Assyrian architecture, in which it is also used.

VOLU'TIDÆ, a family of gasteropodous mollusks, of the section *pectinibranchiata*, all marine, having a spiral shell, which is turreted or convolute, the aperture notched in front, the *columella* obliquely plated; no operculum. The animal has a very large foot, and a recurved siphon. The species are numerous, and abound chiefly in tropical seas. Many of them have very beautiful shells, much prized by shell-collectors. Several small species are found on the shores of Britain, of which *voluta tornatilis* is the only one that is not rare. This genus makes its appearance in the cretaceous strata, and increases in numbers in tertiary deposits, no less than 50 species being known in the pleistocene.

VOLVOX, a genus of minute organisms, the type of a family called *volvocineæ*, now regarded as vegetable, and ranked among *protophytes*, but which were at first supposed to be animals, and were reckoned by Ehrenberg among *infusoria*. They are globular, or nearly so, are found in stagnant water, and move slowly through the water, revolving round an axis, by the agency of numerous cilia (q.v.), which project from their surface; one pair arising from each of the numerous component cells of the sphere, and passing through their common gelatinous envelope. Both sexual and asexual multiplication take place; in the former case, certain cells enlarge to form oospores, while others divide and redivide, so producing a mass of tiny segments, which are set free as ciliated antherozoids, and unite with the oospores, which ultimately divide to form new colonies. In asexual multiplication, eight cells of the ball undergo repeated division, so forming new spheres, which are set free by the breaking up of the parent. These frequently exhibit, even while within the parent globe, a rotary motion similar to its own. The presence of starch in the interior of the *volvocineæ* has been detected by means of iodine, and is regarded as a conclusive proof of their vegetable nature. The most common and best-known species is *volvox globator*, which is just visible to the naked eye. It is a transparent sphere, having its surface studded with innumerable green spots, united by a beautiful net-work. From 6 to 20 young are often to be seen in its interior.

VOLVULUS (Lat. *volvere*, to twist) is the term used in medicine to signify a twisting of the intestine, producing obstruction to the passage of its contents. There are three distinct varieties of rotatory movement capable of giving rise to volvulus—(1) A portion of intestine may have become twisted on its own axis, and, in that case, even semi-rotation brings the intestinal walls into contact, so as to close the passage. This is a rare condition, and only occurs in the ascending colon. (2) The mesentery (q.v.), or a part of it, may be twisted into a cone, dragging the intestine with it; the mesentery being the axis, and the intestine being rolled up upon it. This form occurs in the small intestine. (3) A single portion or a coil of intestine may afford the axis round which another portion, with its mesentery, is thrown, so as to compress it, and close the passage. A coil of small intestine, the sigmoid flexure or the cæcum (see DIGESTION, ORGANS OF), may form the axis. All these varieties occur chiefly in advanced life, and their seat is commonly toward the posterior unyielding wall of the abdominal cavity, the smoothness and yielding nature of the parts anteriorly rendering such an event almost impossible. The *symptoms* of twisting of the intestines, especially of the sigmoid flexure, which is the most common seat of the affection, are usually very well marked from the beginning. Great pain is suddenly experienced in a small circumscribed spot of the abdomen, obstinate constipation usually setting in from that date. If the sigmoid flexure, which lies just above the rectum, is the seat of the twisting, the abdomen soon becomes distended, especially on the left side, the distention being much more marked than when the twist is in the small intestine, as might physiologically have been expected. Vomiting, often constant and copious, is usually present. These cases are so desperate in their nature

that it is needless to enlarge upon their treatment. Attempts to remove the displacement by injecting water or air into the intestine by means of a long tube have often been made, but with very slight success. Mr. Pollock, in his article on "Disease of the Alimentary Canal," in Holmes's *System of Surgery*, remarks that "relief in twist of the sigmoid flexure is just possible without opening the abdomen, provided the long tube be introduced into the distended gut, its contents drawn off, and the twist be reduced by the altered position of the bowel. But no operation for the ultimate relief of the patient will be successful unless the intestine be unloaded first, and the twist then reduced."—Vol. ii. p. 158. The operations that have been proposed for the relief of this and other intestinal obstructions are so often fatal, and, even when successful, leave the patient in so wretched a state, with an artificial outlet for the discharge of the contents of the bowels, that it is doubtful whether they should be recommended. It is simply a choice between almost certain death in a few days and a possible chance of a prolonged (but usually a miserable) existence. There are, however, a few rules that should be universally known and attended to—viz., wherever symptoms such as we have described occur, aperients should only be given by the rectum, while opium should be freely given by the mouth. Leeches and hot fomentations should be applied to the seat of pain; and all solid food should be prohibited, the nourishment being given solely in the fluid form.

VO'MER, a bone which, in the human skeleton, forms part of the middle partition of the nose, and the lower edge of which fits into grooves between the apposed surfaces of the palatine processes of the upper jaw and palate-bones. It exhibits many modifications in the different classes of *vertebrata*. Its position is indicated in the figure of *archetype vertebrate skeleton*, in the article SKELETON. It is specially noticed here because of the frequent occurrence of the term vomer in articles on fishes—a very important character being often found in the presence or absence of teeth on the vomer; that is, along the middle line of the roof of the mouth.

VOMITING consists in the stomach emptying itself through the gullet and mouth. It is preceded by a feeling of nausea, a flow of saliva in the mouth, and the breaking out of perspiration; the countenance grows pale, a feeling of weakness spreads over the whole body, and the pulse becomes slow. At last the muscles of the abdomen and the diaphragm strongly contract, and the whole contents of the stomach are ejected with greater or less violence. The first matters to be ejected are the food and drink present, then mucus from the stomach and esophagus, and lastly, bile from the duodenum. In cases of disease, abnormal substances are sometimes vomited, such as blood, fragments of the intestines, and even excrementitious matters. When the vomiting is over it is followed by languor and drowsiness, or, if the excitement was inconsiderable, the usual state immediately returns.

The causes of vomiting are various. In the first stages of infancy it is almost normal, and occasions no disturbance of the system. In many animals, too, it is a normal function of life, as when birds of prey reject the hair and feathers of their victims. The infant gets rid of the superabundant milk it swallows by throwing it up with no trouble. Some persons can excite themselves to vomit by swallowing air.

The immediate causes of vomiting may be reduced, according to Dr. Carpenter, to the three following categories: "(1) The contact of irritating substances with the mucous membrane of the stomach itself; these, however, cannot act by *direct* stimulatiom upon more than its own muscular coat; and their operations upon the associated muscles must take place by *reflexion* through the nervous circle furnished by the pneumogastric and the motor nerves of expiration. (2) Irritations applied to other parts of the body, likewise operating by *simply-reflex* transmission; as in the vomiting which is consequent upon the strangulation of a hernia, or the passage of a renal calculus; or in that which is excited by the injection of tartar emetic or emetin into the circulating current, when these substances probably produce their characteristic effect by their operation on the nervous centers. (3) Impressions received through the *sensorial* centers, which may be either sensational or emotional, but which do not operate unless they are *felt*. In this mode seems to be excited the vomiting that is induced by tickling the fauces, which first gives rise to the sensation of nausea; as well as the vomiting consequent upon disgusting sights, odors, or tastes, and upon those peculiar internal sensations which are preliminary to sea-sickness. The *recollection* of these sensations, conjoined with the emotional state which they originally excited, may itself become an efficient cause of the action, at least in individuals of peculiarly irritable stomachs, or of highly sensitive nervous systems."—*Principles of Human Physiology*, 6th ed., p. 77.

According to the oldest doctrine respecting vomiting, it was held to arise solely from convulsive movements of the stomach, which was thought to take on a motion contrary to the usual peristaltic motion. Bayle advanced the opinion, that the stomach is quite passive in the operation, and that its contents are emptied entirely by its being compressed through the contractions of the abdominal muscles and the diaphragm. An apparently conclusive experiment of Magendie's, in which the stomach was removed, and a bladder substituted for it, had more recently (in 1813) satisfied most physiologists as to the passiveness of the stomach in vomiting, until Béclard and Budge showed the insufficiency of his experiment. It is found, in fact, that in vomiting there are two sets of actions, viz. (1) contractions of the abdominal walls, while the diaphragm remains

fixed, and forms a support to the stomach, and (2) the stomach itself performs jerking movements, the pylorus, or inferior orifice, at the same time closing, while the cardiac sphincter relaxes, without which last-named action vomiting is impossible; and that either of the two kinds of movement—the abdominal or the stomachal—may eject the contents of the stomach into the gullet.

In the treatment of vomiting, we must consider it as a symptom rather than a malady. Where the stomach is irritated, relief is afforded according to circumstances, by drinking cold water, aerated or soda water, or, if necessary, by opium or nux vomica. Cold applications outwardly also do good. In other cases, infusions containing ethereal oils —camomile, coffee, etc.—astringents, or correctives for acidity—magnesia, soda, etc.— are the fitting remedies. When the irritation is in the brain, the best remedy is a horizontal position, with composure and darkness. If a person in sound health is suddenly seized with vomiting poisoning may be suspected.

VONDEL, Joost van den (pr. *Vōst*), the greatest Dutch poet, was born at Cologne, Nov. 17, 1587, his parents, who were Anabaptists, having fled from Antwerp to avoid persecution. His maternal grandfather, Peter Kranen, ranked among the poets of Brabant. When freedom began to raise the head in Holland, the elder Vondel removed with his family to Utrecht, and afterward to Amsterdam, where he prospered in trade. The poet's education in boyhood was limited to reading and writing, but his perseverance and love of study enabled him in after-life to become intimately acquainted both with ancient and modern literature.

At the early age of 13, his poetical efforts were praised by Hooft. In his 23d year, he married Maria de Wolf, to whose clever management Vondel chiefly left his business as a hosier, while he devoted himself to study and poetry. The tragedies of Vondel are very numerous, and the grandest specimens of Dutch literature. His satirical writings and epigrams are full of fire, energy, and spirit. One of his most remarkable pieces is *Lucifer*, published in 1654, strikingly resembling Milton's *Paradise Lost*, which appeared thirteen years later. Vondel took an earnest and active part in favor of the Remonstrants, Grotius and Oldenbarneveld, drawing down on himself the anger both of the clergy and court, whom he attacked with the keenest satire.

Gysbrecht van Aemstel, Adam in Banishment, Palamedes, The Batavian Brothers, Solomon, Samson, Adonijah, Noah, or the Destruction of the Old World, Mary Stuart, etc. are splendid efforts of genius. *The Harpoon, The Horse-comb*, and the *Decretum Horribile* are stinging satires on the ruling powers both in church and state. Vondel's translations from the Greek and Roman writers are numerous, the *Metamorphoses* of Ovid having been rendered into Dutch verse when he was 84 years old. Vondel left no subject untouched, no measure untried. His works (9 vols. quarto) contain many sea-songs, and more than 100 odes. Many of the later poems were written with a strong Roman Catholic spirit, he having joined that church about 1640. Through the imprudences of his son, to whom he had given his business, Vondel fell into straitened circumstances, and in 1658 accepted a situation in the city pawnbroking office. In 1668, the magistrates allowed him to retire with his salary of 650 guilders yearly, which kept him above want. He was of moderate stature, well made, and had an eagle eye. After his powers of body and memory had begun to fail, he could still read without glasses. He died calmly, 1679, aged 91. Fourteen poets acted as his pall bearers.

VONITZA, a town on the coast of Greece in the province of Acarnania and Aetolia, on the southern shore of the gulf of Arta and about 48 m. n.w. of Mesolenghi. Pop. about 3000.

VON SIEBOLD, Karl. See Siebold, Karl von.

VON SYBEL, Heinrich. See Sybel, Heinrich von.

VOODOOISM is a species of demonology in vogue especially among the Creole negroes of La., and said to have been derived from their ancestors in Africa. St. John's eve is devoted to the mystic rites of the Voodoos; they gather in some secluded spot, and there they go through their Voodoo dances and contortions, accompanied by a rude kind of music. Their magic is said to consist in a knowledge of several very subtle poisons, which produce a slow and lingering death through exhaustion. Their power is much feared by the other negroes.

VOORHEES, Daniel W., b. in O., 1827; graduated, Asbury university, 1849; studied law and practiced in his native state. He became a democratic politician of influence, was U. S. district attorney, 1858–61, and served as member of congress from 1861 to 1865, and from 1869 to 1871. In 1877 he was appointed U. S. senator to complete an unexpired term, and in 1879, 1885, and 1891 was elected for full terms. He d. in 1897.

VOORNE-EN-PUTTEN, the name of an island belonging to the province of South Holland, lying between Haring Vliet and the mouth of the Meuse, west of Beijerland. Originally two islands, the soil has gradually become continuous through the silting up of the river that cut through it. The island is traversed by the Voorne canal, emptying into the Haring Vliet near Helvoetsluys.

VOPADEVA is a celebrated grammarian of India. He wrote a grammar entitled *Mugdhabodha*, which is held in high repute, especially in Bengal, and was commented upon by *Durgadâsa*. (Both text and commentary have been edited at Calcutta in 1861; previous editions contain merely the text of Vopadeva's grammar). It differs from the

great work of Pân'ini (q.v.) in its arrangement as well as in its terminology; and without commentary of Durgadâsa, would not yield by far the information that may be derived from Pân'ini's grammar.

VORANT, in heraldry, a term applied to an animal represented as swallowing another; as, sable, a dolphin naiant; vorant a fish proper.

VORARLBERG, a district of west Austria, which with Tyrol forms the administrative province of Tyrol and Vorarlberg, which has an area of 11,324 sq. m., and a pop. (1890) of 928,769. Vorarlberg alone has an area of 1005 sq. m., and a pop. '91, of 116,073. It is bounded by Bavaria and on the n. and n.e., Grisons on the s., Liechtenstein and St. Gall on the w., and lake Constance on the n.w. It is traversed by the Arlberg mountains, from which it takes its name. It is drained by the Aach, Ill, Fussach, and Lech rivers. The soil is fertile, producing fruit, wine, cereals, and dairy products. Capital, Bregenz.

VORMEN, a river in Norway, 200 m. long, rising by many heads in the Langfield and Sagnefield mountains. It is 2000 ft. above the level of the sea, and, flowing through the valley of the Gudsbransdale, expands into the lake of Mjösen. Above the lake it is called Laugen; from this point to the Glommer, 28 m. n.e. of Christiania, it bears the name of Vormen. The lake, 80 m. long and 8 m. broad, 600 ft. above the sea, is the center of a brisk trade, and the river through its entire length teems with salmon and salmon-trout.

VORONE'J, or VORONETZ (pronounced *Voronesh*), a government in the s. of Great Russia, bounded on the s. by Little Russia and South Russia. Area 25,443 sq. m.; pop. '94, 2,755,400, consisting of Russians and German colonists. It is watered by the Don, its two navigable tributaries, the Voronej and Khoper, and other streams. The soil, mostly a black mold, is generally fertile, and great crops of grain—wheat, rye, barley, oats, and millet (which supply the inhabitants and local distilleries, and are exported)—are produced. Cattle and horses of a good breed are reared; the best studs belong to the crown. The principal manufactured articles are oil, brandy, beer, cloth, beet-root, sugar, skins, wax candles, soap, tobacco, and potash; and corn, tallow, hemp-seed, cattle, and horses are exported. Capital, Voronej.

VORONE'J, a t. of Great Russia, capital of the government of the same name, stands on the right bank of the Voronej, 150 m. s.w. of Tambov. It was founded in 1586 as a bulwark against Tartar invasion. Peter the Great, who had previously visited the town, built a fortress and a dockyard here in 1694. Besides two cathedrals, the town has many important civil, ecclesiastical, and educational institutions. The commerce of Voronej is extensive, the chief articles of trade being corn, hemp-seed, and tallow. Pop. '97, 84,015.

VORONTZOFF, MIKHAIL, 1772–1856; b. St. Petersburg; entered the Russian army and took part in the campaign against the Turks, and against Napoleon. He was appointed governor-general of South Russia and Bessarabia in 1823, and succeeded Menshikoff in 1828. He became governor of the Caucasus in 1844, conducted a campaign against Schamyl, and resigned from the army in 1854. In 1856 he was given the title of field marshal, and made governor of Odessa.

VÖRÖSMARTY, MIHÁLY, 1800–55; b. Hungary; studied law in Pesth, but devoted himself to literature. Of his epic poems, *Zalán Futâsa* and *Eger*, and of his dramas, *King Salomon* and *Kont*, are the best. His patriotic song, *Szózat*, was immensely popular in the revolution of 1848. At the time of his death he was engaged in translating Shakespeare into the Hungarian language.

VOR'STIUS, CONRAD, 1569–1622; b. Cologne; studied at Heidelberg; appointed professor of divinity at the gymnasium of Steinfurt. From his published treatises, *De Prædestinatione*, *De Sancta Trinitate*, and *De Persona et Officio Christi*, he was suspected of Socinianism, but made a satisfactory defense at Heidelberg; succeeded Arminius as professor of theology at Leyden, 1610; wrote a treatise, *De Deo*, which was burned by the hangman in London and Oxford; was deposed, 1612, and condemned by the synod of Dort as a heretic, 1619.

VORTEX (Lat. a whirlpool). Till lately, it was a reproach to hydrodynamics that the theory of vortices or eddies in fluids had not been properly brought under the domain of mathematical analysis. Even now, the problem has only been partially solved by the labors chiefly of Stokes (q.v.) and Helmholtz (q.v.), as their beautiful investigations apply only to *perfect* fluids, that is, fluids which oppose no frictional resistance to change of shape. In ordinary motions of perfect fluids, such as currents and waves, the instantaneous change of shape of a small spherical portion makes it an ellipsoid by simple extensions and compressions *without* rotation. The essential characteristic of vortex-motion is, that it involves rotation of some parts of the fluid. Helmholtz has shown that this rotational or vortex-motion remains with the parts of the fluid which first have it, and cannot be transferred. We can conceive no process by which vortex-motion could be given to, or taken from, a perfect fluid; for to our reason fluid friction (which does not exist in a perfect fluid) would seem to be indispensable. On such abstruse subjects we cannot of course enter here; but one result of Helmholtz's investigations is so curious that we must mention it. We are all familiar with those singular smoke-rings which are produced when a mortar is fired; or when, on a smaller scale, a bubble of phosphurcted hydrogen takes fire in air, or a smoker skillfully emits a puff of tobacco-smoke. A

very simple mode of producing them, on even a large scale, is to bore a hole in one side of a box, remove the opposite side, and substitute a cloth or sheet of india rubber for it. A slight blow on this membrane ejects a vortex-ring from the hole. To make this vortex visible, we may burn phosphorus or moistened gunpowder in the box; or still better, sprinkle its interior with ammonia, and introduce a vessel containing common salt and sulphuric acid. The sal-ammoniac cloud which fills the box is admirably adapted to display the rings. Besides a progressive motion as a whole, the ring revolves about its own central or medial line. Suppose two such rings to follow each other, with their planes parallel, and their centers moving in the same line, Helmholtz shows that (at least in a perfect fluid) the foremost will relax its speed, and spread out into a larger ring, while its follower will contract, and quicken its pace, till it passes *through* the other, which in turn becomes the pursuer, and so on. This very curious result may be realized in a tea-cup, by drawing the half-immersed bowl of a tea-spoon along the surface of the tea for a short way, and withdrawing it. Two little whirlpools, or vortices, are then seen moving side by side. They are sections of the half vortex-ring which has been formed in the liquid by the spoon. A second half-ring may be at once sent after them by another stroke of the spoon, and the phenomenon above described will be obtained. When, on the contrary, two such vortex-rings *meet*, their centers moving in one line, they both spread out, and relax their speed indefinitely. This is obtained in a liquid by letting the half vortex-ring impinge directly on the side of the vessel, when it spreads out, and relaxes its speed; just as if there were no boundary of the fluid, but a second vortex-ring occupying the place of the image of the first which would be formed by a plane mirror substituted for the side of the vessel. When one vortex-ring impinges obliquely on another, it rebounds from it, and both are thrown into vibration, their form of equilibrium being circular. They act in fact in this respect like solid India rubber rings. By forming them from an elliptic aperture, they are produced in a state of vibration. A square aperture gives them in a different state of vibration.

The impossibility of producing or destroying vortex-rings in a perfect fluid—save by creative power—has led sir W. Thomson (q.v.) to regard the ultimate parts of matter as vortices of various kinds in a perfect fluid.

The word vortex has also come into use in connection with Descartes's once celebrated theory of the universe, given in his *Principia Philosophiæ*. In this the rotation of the planets about the sun, the satellites about the planets, etc., were explained (!) by the hypothesis of vortices forever whirling about the central body. Descartes was a good mathematician, but in natural philosophy he preferred metaphysics to experiment, and of course erred enormously. But he is not to be laughed at: mistakes more ridiculous than his are gravely propounded at the present day.

VORTICEL'LIDÆ, a family of *infusoria*, remarkable for beauty, and containing a great number of species, to which, from their form, the name of *bell* or *bell-flower animalcules* is often given. The genus *vorticella* consists of minute cup-shaped or bell-shaped creatures, each placed at the top of a long flexible stalk, the other end of which is attached to some object, as the stem or leaf of an aquatic plant. Around the edge of the bell or cup is a fringe of rather long cilia, the motion of which brings food to the mouth. The stem is flexible, and is sometimes stretched out to its full length, sometimes contracted in a spiral form. The contraction takes place instantaneously upon any alarm, the cilia at the same time vanishing; and it is very interesting to watch a group of *vorticellæ*, which may often be easily done with a Coddington lens, when they adhere to the inside of the glass of an aquarium. The stem is often beautifully branched, the *vorticella* becoming a compound animal, like many zoophytes, and the whole contracts or is extended at once, The stem, slender as it is, is a tube, through the whole length of which runs a minute muscular thread. A cup or bell of a *vorticella* sometimes develops a new fringe of cilia at its point of junction with the stem, becomes detached from the stem, and begins to move freely through the water, till it finds a new place on which to fix itself, reproduction thus taking place by gemmation. Reproduction also takes place by encapsulation. See INFUSORIA. To the family vorticellidæ belongs the genus *stentor*, having a trumpet-shaped body, and therefore receiving the popular name of trumpet animalcules. They swim freely through the water, at the same time rotating on an axis, and attach themselves to objects by a sucker at the lower or narrow end. They have a fringe of cilia round the mouth, and the body of some species is covered with cilia. They are very voracious. They may often be found adhering to a twig or the stem of an aquatic plant, collapsed into minute masses of green jelly.

VOSGES, a dep. in the n.e. of France, formed out of the s. part of the old province of Lorraine, is bounded on the n. by the departments of Meuse and Meurthe, and on the e. by Alsace-Lorraine. Area, 2,266 sq.m.; pop. '96, 421,412. The surface is mountainous the territory being traversed not only by the Vosges mountains, which run along its e. border, but also by the Faucilles mountains, which cross the dep. from e. to west. The chief rivers are the Moselle, and its tributaries the Meurthe, Madon, and Mortagne, all of which flow in a N. or N.W. course through this department. The mountains in the e. are covered with vast forests of beech and fir, and at the base of the mountains are tracts of pasture or rolling infertile plains. The w. part of the dep. called the *plaine*, is very fertile in cereals, vegetables, and fruits. Among the hills, the

climate is cold; on the plains it is humid. An excellent cheese, called Géromé, is produced. Embroidery, cotton and linen goods are produced, and bleaching and dyeing are carried on. Mineral riches abound, there being iron, lead, copper, cobalt, and antimony mines. The dep. is divided into the five arondissements, Épinal, Mirecourt, Neufchâteau, Remiremont, Saint-Dié. The capital is Épinal.

VOSGES MOUNTAINS (Lat. *Vogesus*, Ger. *Vogesen* or *Wasgau*), a range of mountains in the n.e. of France and the w. of Germany, run from s. to n., on the left bank of the Rhine, from the borders of the departments Haute-Saône and Doubs, n. to Mainz, and separate Alsace from the French departments of Vosges and Meurthe and the German Lorraine. The range runs parallel with the Schwarzwald or Black Forest in Baden and Würtemberg, on the right bank of the Rhine, and forms the western border of this part of the Rhine basin. The summits are rounded and regular in outline, and are called *ballons*. The chief of them are the Ballon de Guebwiller, 4680 ft.; le Hobeneck, 4429 ft.; and the Ballon d'Alsace, 4085 feet. They are covered with forests, and there are some minerals, coal being the most important.

VOSS, Johann Heinrich, one of the foremost classical writers of Germany, was b. in 1751 at Sommersdorf in Mecklenburg, of poor parents. In 1772 he went to the university of Göttingen, and there joined the "Hainbund," an association of young poets, at the head of whom stood Bürger and Boje. Voss first intended to devote himself to theology, but soon exclusively turned to Greek and Roman antiquities, under Heyne's auspices. In 1778 he went from Wandsbeck, whither he had gone for the purpose of editing the *Musenalmanach*, to Otterndorf, in Hadeln, where he prepared his translation of the *Odyssey*. This appeared in 1781, and was received with universal applause. In the next year he became rector of Eutin, whence, in 1789, he issued his German translation of Virgil's *Georgics*. This was followed, in 1793, by a new and revised edition of the German *Odyssey* and *Iliad*, which, however, did not meet with as favorable a reception as the first. His contests with Heyne (q.v.) gave also rise chiefly to his *Mythological Letters*, which appeared in 1794. Among his purely German poetical works, *Luise*, an idyl (1783, revised 1795), takes a foremost place. In 1799 he issued the whole of Virgil in a German translation. In 1802 he went to Jena, where he wrote the celebrated review of Heyne's *Iliad*. In 1805 he was called to Heidelberg, where he wrote annotated German translations of Horace, Hesiod, Theocritus, Bion, Moschus, Tibullus, and Lygdamus. In 1821 he published a translation of Aristophanes, and a new edition of Horace and Virgil. Among other literary labors must also be mentioned his translation (with the aid of his two sons) of Shakespeare's works, which, however, is very inferior to Schlegel's. In opposition to Creuzer's *Symbolik*, he wrote an *Antisymbolik* (1824), in which he lifted up his voice against exaggerated praises of heathen mysticism; and one of his last papers was a violent denunciation of his former friend Stolberg, who had turned Roman Catholic. He died at Heidelberg in 1826. Among his translations from modern languages may be mentioned that from Galland's *Arabian Nights*, and that of Shaftesbury's works. A brief mention may also be made of his two sons: (1) Heinrich, b. 1779, a philologist of merit, who assisted his father in his Shakespeare translation, and who was a great friend of Jean Paul's. He had intended to edit the latter's works, but died before him, in 1822. (2) Abraham, b. in Eutin, professor of the gymnasium at Kreuznach, who completed the Shakespeare translation. He died in 1847.—See Paulus, *Lebensund Todeskunden von J. H. Voss* (Heidel. 1826).

VOSSIUS, Gerard, one of the most distinguished scholars of the first half of the 17th c., was b. of Dutch parents near Heidelberg, where his father was a Protestant minister. His father's name was John Voss, but he, after the fashion of the time, had Latinized it into Johannes Vossius, and hence his son called himself Gerardus Johannes Vossius, that is, Gerard, the son of John. In 1578 the family returned to Holland, and settled at Dordrecht, where Vossius went to school. He afterward distinguished himself at the university of Leyden; and when 22 he returned to Dordrecht, to become the principal of the school, of which he was the most distinguished pupil. He married shortly afterward, but his wife died in 1607, leaving a family of three children. In the same year, he again married, and by his second wife he had two sons and five daughters. In the earlier part of his life, Vossius does not appear to have published much, but he became known to his countrymen as a scholar and theologian; and his assiduity in study may be inferred from the fact that he would never allow a friend to stay with him more than a quarter of an hour. In 1615 he became principal of the theological college of Leyden, and while holding this appointment, published a work on Pelagianism (*Historia Pelagiana*). In it he spoke of the Arminians in an apologetic tone, and thereby brought down upon himself the wrath of a large section of the Dutch clergy; which caused him to be deprived of his office in the theological college, and of the income derived from it. His work had attracted attention in England, and it was some compensation to him that he received from archbishop Laud an office which brought him £100 a year without its being necessary he should live out of Holland. Chiefly, it appears, to secure the means of supporting his family, he retracted the opinions he had expressed, in his book *De Historicis Latinis*, published in 1627, and he became reconciled to the church. In 1631 he was appointed professor of History in a new university at Amsterdam, where he seems to have devoted himself to the completion of the great works on which his fame

rests. Among the most important of these not mentioned above were. *Aristarchus sive de Arte Grammatica, Libri VII.; De Historicis Græcis, Libri IV.; Commentariorum Rhetoricorum sive Oratoriarum Institutionum, Libri VI.; De Veterum Poetarum Temporibus, Libri II.* In 1649, Vossius was climbing the ladder of his library when it broke; he fell under the shelves and books, and died of the injuries he received.

The children of Vossius were remarkable for beauty, accomplishments, and learning. Grotius said of Vossius in epigrammatic Latin, that it was doubtful whether by his books or his children he had contributed most to adorn the age. Five of his sons, Denis, Francis, Gerard, Mathew, and Isaac, are known as authors.

VOSSIUS, Isaac, a scholar and theologian, was the only son of Gerard Vossius who survived him. He was born at Leyden in 1618. When 21 he published an edition of the *Periplus* of Scylax, the Greek geographer, with a Latin translation and notes. He afterward traveled in Italy, collecting valuable manuscripts. In 1648 he took up his abode at the court of queen Christina of Sweden; but in 1658, in consequence of a quarrel with Salmasius, he returned to Holland. In 1670 he came to England, and here, although he openly scoffed at religion, he was appointed by Charles II. a canon of Windsor, and had apartments assigned him in the Castle. He died there in 1689, and it is recorded that on his death-bed he refused to take the sacrament, until one of his colleagues argued that he ought to do so for the honor of the chapter. His works are numerous, but not so important as those of his father.

VOTING BY MACHINERY. Every one possessing the privilege of suffrage is supposed to read and understand the special routine laws governing the act of voting. Yet the wording of such enactments will rarely leave an impression on the minds of more than 25 in 100 voters, and an expert authority has said that there are never more than 15 persons out of 100 who have in their minds an accurate idea of the meaning of the law. Suppose a voter wishes to drop certain candidates on a party ballot and substitute others. In a few cases he may have made his selections beforehand, but the great majority of those exercising the franchise are not apt to take such precautions. Then the confusion begins, and it is well known that the act of procuring slips of, say, a Republican candidate by a Democrat is often a source of personal annoyance. Absolute secrecy in voting becomes impossible, and there is no question but that the character of the ballot, whatever it be, is known to some one in the polling-booth as soon as it is seen.

A cynical political statistician has said that twenty per cent. of all elections held in the United States were effected by "fraudulent returns." That, even when intentions were honest, there was a constant five per cent. of error. That the larger the vote, with an increasing number of candidates, the greater the errors. That there was rarely a "voting balance account" which was not forced. The conclusion arrived at was that to bring about a wrong count, or a "hitch," was that exact condition the political trickster was striving for. In delay was victory—for the side which massed the rascals. It is not worth while to dilate on the methods employed by political tricksters to defraud the honest American citizen of his rights. The materials already collected are as voluminous as they are startling. That they should have been carried out so long shows the apathy of "the intelligent voter."

Human means being apparently unable to cope with the difficulty, the question has been asked repeatedly, Can the actual business of voting, with the necessary factors of secrecy, accuracy, ease, and speed, be encompassed by a mechanical device? That one element, speed, would mean not alone rapidity in the personal act of voting, but ability to sum up at once the total results of the canvass, to eliminate the vexatious delay in additions, to nullify the blunders of indifferent accountants, and to keep besides the exact tally of all the voters who had entered the polling-booth. A recent invention known as the Myers Ballot machine accomplishes these results with perfect success.

This ingenious device may be described as a small steel room with a door of access and of exit. It is easy to get in, to vote, and, after voting, to get out again; but when the voter goes out, and is in the vestibule of the booth, he cannot return to vote if he be a repeater, for then the whole of the voting mechanism, entrance door and all, is locked up. It is only when he emerges entirely that the door of the entrance is open again. Then, too, the voting mechanism is released. The man is seen by those outside to have gone through with his voting, and he cannot return. The individual action of opening or closing a door by the voter does the whole business for him.

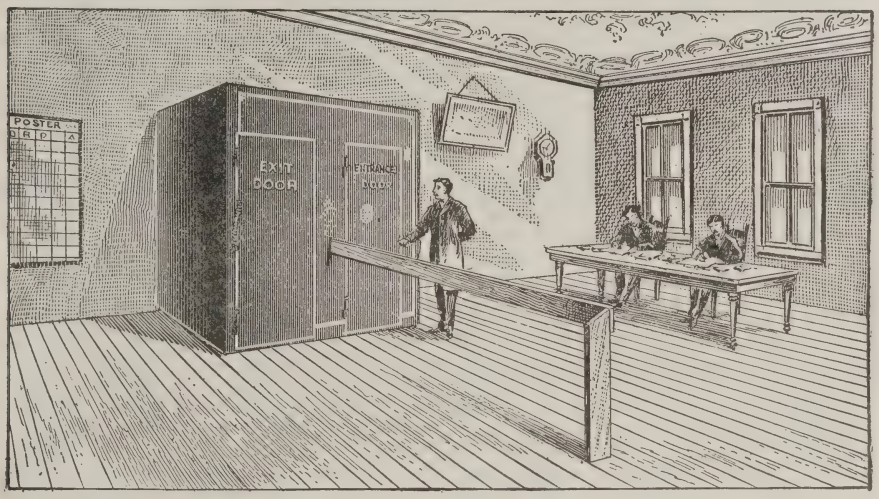
Before the voter enters the steel booth he has consulted the lists prepared by the proper authorities. That is always done. The journals invariably print them in their regular order, a governor standing at the head of the list, and, say, the game-constable last.

It has been suggested over and over again that for the illiterate certain colors should be adopted. In the ballot-machine colors are adopted. The Democratic list is yellow, the Republican red, the Prohibition blue. If there were other parties, other colors could be used, as white letters on a black ground, or the reverse. Colors are to help the voter, and not the machine.

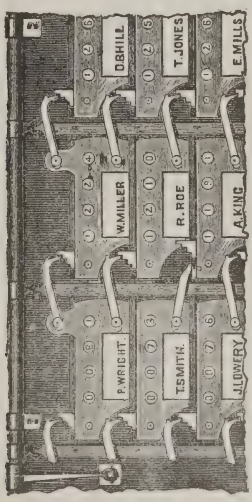
Say there are but three parties in the political contest, and some general question, as a constitutional amendment, is to be discussed with a simple "Yes" or "No." Then there

is a fourth element introduced. Having made up his mind what he intends doing, knowing the color of his party, or not knowing it, the inspector opens the door of the steel booth and the voter at once has access to the interior. When the door of entrance is closed he is entirely hidden from sight, but the door is not locked. The little room is perfectly well lighted by means of a gas-jet or lamp. The man finds a number of vertical columns with push-knobs projecting three inches from the partition. These are painted the same color as the ballot cards beside them.

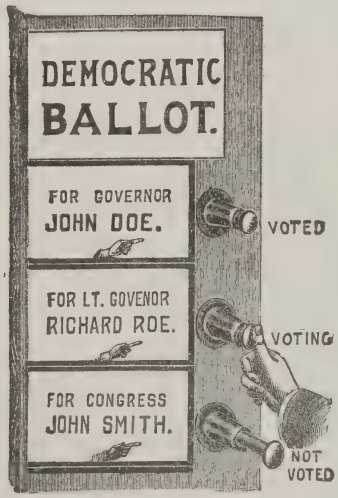
To the left of each column of knobs are the names of the candidates, printed in large legible characters, with the office they wish to fill. All the names and the knobs are in a perpendicular line, beginning, say, with a governor, and ending with a constable. This plan, if there be three or six parties in the field, brings all the candidates for the same office on the same horizontal or cross line. Each perpendicular line has on



POLLING-BOOTH.



BACK OF MACHINE.



FRONT OF MACHINE.

top "Democratic Ticket," "Republican Ticket," or "Labor Ticket." The voter may begin with the No. 1 knob, which notes, say, the Democratic governor's name. He pushes in the knob until it catches, and it remains fixed. He cannot move it out again and vote for that governor twice, or for any other governor. By that act he has done several things he does not know of. He has locked up the governors of the Republican and the Labor party. They are fixed now, and he can push all he pleases and nothing is recorded. The same result follows after voting for any one man on any cross line, it makes no matter in which column.

A voter, finding every candidate of his party to his taste, votes the whole Democratic ticket. He pushes in the 12 or more up-and-down knobs. He has accomplished

his task of coming into the booth, voting, and getting out in less than ten seconds. As has happened quite frequently, a great many honest people ignore a nominee and split their ticket, selecting a candidate from another party. Then the voter would have pushed in the Republican knob and the Democratic nominee's name would have been locked. Then he ran down the names of the other Democratic candidates, pushing in the knobs, and maybe was five seconds more in performing the duties of a free man. How is the count kept? On the reverse side of the perforated steel partition, opposite to each of the candidates' names, and in communication with a knob, is a mechanical counter which bears the same name as the knob. Before the polling begins the inspectors arrange every one of these counters or indicators at zero, and then fix to the steel door, which covers the recorders, their seal.

When the voting is over the covering is removed, and the register shows the exact number of times a knob has been pushed in, or a candidate voted for. In fifteen minutes at the outside, even when thirty or more people are to be separately voted for, with two questions, the affirmative or negative, the numbers indicated by the register can be copied. There is an additional counter, which is always visible, and shows the exact number of people who have voted. In short, this machine actually exceeds human possibility by discounting the errors of the voter and the carelessness of inspectors, and, what is more, effectually prevents fraud. The practical working of this apparatus is clearly demonstrated by actual results at regular elections. Four hundred and sixty-five *bonâ fide* votes have been polled and counted within two hours, and this year (1894) 2167 votes were polled in 9¾ hours in one polling-room.

VOTIVE (Lat. *votivus*, given in virtue of a vow; Fr. *votum*, a vow), in ecclesiastical use, signifies the class of actions, offerings, or memorial records or observances, which are intended either as the fulfillment of a vow, or as a commemoration of the accomplishment of the prayer which accompanied the vow. Of such votive engagements there are numerous examples in the Old Testament (Lev. xxii. 18, Deut. xii. 6), as well as in the ancient religions of the Gentile world; and the ecclesiastical historian Theodoret (*De Cur. Græc. Affect.*, i. 8) alludes to the practice in his own day of hanging up, in the churches dedicated to the saints, little models of hands, feet, eyes, etc., in votive commemoration of the cure of lameness, blindness, and other maladies supposed to have been obtained through their intercession. The same practice continued thoughout the succeeding centuries and throughout the mediæval period, and still prevails in Roman Catholic countries, especially in Italy and southern Germany. Votive offerings, often of very considerable value, may be seen in the churches of most of the great sanctuaries (q. v.), and in other churches in special repute as places of devotion. The offering very frequently takes the form of a votive tablet, with an inscription detailing the event on which it is founded. Sometimes the offering is simply marked with the words *ex voto*, "in fulfillment of vow;" sometimes it is accompanied by a model in wax, in wood-carving, or even in precious metals, similar to those alluded to by Theodoret; and occasionally by a model of some object, which is meant to recall the memory of the favor received, as of a ship, in case of escape from shipwreck, etc. Many of the great churches, hospitals, monasteries, and other religious monuments of the middle ages and of later times were built *ex voto;* and the treasuries of most of the rich cathedrals and other churches abroad contain objects of great value, the result of votive engagements on the part of the donors. The name *votive* is also applied in the Roman Catholic church to the mass or other service, when it is celebrated—as is permitted on certain days and in certain seasons—not according to the rite prescribed for the day itself, but according to a rite selected by the celebrant himself from a number of such "votive masses" and "votive offices," as "of the Passion," "of the Holy Trinity," "of the blessed Virgin Mary," etc., which are contained in the missal and breviary.

VOUET, Simon, 1582–1649; b. Paris, son of Laurent, a painter. He is called the founder of the French school of painting; studied with his father, and accompanied the French ambassador, baron de Sancy, to the Porte in 1611. After one interview only, he painted from memory an excellent likeness of the sultan Achmet I. Subsequently he visited Venice and Rome. At Rome he received a pension of 2,000 francs from Louis XIII. and became president of the academy of St. Luke; in 1627 principal painter to the king with apartments in the Louvre, employing Le Brun, Le Sueur, Mignard, Du Fresnoy, and others to assist him in painting ceilings, galleries, altar-pieces, small religious pieces, and portraits in oil and crayon. He is said by French historians of art to have done as much for painting as Camille did for the drama, in France. There are about 200 prints of his works, including the chapel and gallery of the Palais Royal, the altar-pieces in St. Eustache, the chapel of St. Francois de Paule, and the "Presentation in the Temple." He married the painter Virginia di Vezzo, of Velletri.

VOURLA, a town in the vilayet of Smyrna in Asia-Minor, 21 m. w.s.w. of Smyrna. It lies on the edge of a plateau and in the neighborhood are vineyards and olive groves. About 3 miles n. of it, on the gulf of Smyrna, is its roadstead, which is often visited by foreign ships of war. Pop. about 4500, the majority of whom are Mohammedans.

VOUSSOIRS, the individual stones forming an arch, and of which the central one is the keystone. They are always of a truncated wedge-form.

VOW (Fr. *vœu*, from Lat. *votum*), a promise made to God of a certain thing or action good in itself, and within the dominion and right of the person promising. The practice

of vows appears to have formed part of the religious observance of almost all races in any degree civilized; and it largely pervaded the whole ceremonial system of the Mosaic dispensation (Gen. xxviii. 20, Lev. xxvii. 2, I. Chron. [I Paralip. Vulg.] xxix. 9, II Chron. xxxi. 6, Judges xi. 30, Num. xxx. 2, Judith xvi. 19, Jon. i. 16). The stringency of the obligation of fulfilling a vow when once made, is distinctly laid down (Deut. xxiii. 21; Eccles. v. 4, 5); but it is equally clearly stated, that it is by no means a matter of obligation to make a vow (Deut. xxiii. 22). The practice of making vows continued among the Jews in the time of our Lord; and St. Paul, after his conversion to Christianity, continued to conform to this usage (Acts xviii. 18). It would be out of place to enter here into the question, whether this observance was meant by our Lord to form part of his new dispensation, or to discuss how far the practice of vows, especially of chastity, can be traced as in use among the Christians of the 1st and 2d c.; but it appears quite clear that in the end of the 3d, and all through the 4th, the monastic life became general in the east, and soon afterward spread all over the church. See Antony, Paul, Monachism. It is unnecessary to add, that vows, while discarded as a religious observance by the Reformers, enter largely into the system of the Roman Catholic church. The objects of these engagements among Catholics are very various; but they are drawn, for the most part, from what are called the evangelical "counsels," in contradistinction to "precepts" or "commands"—the most ordinary subject of vows being the so-called "evangelical" virtues of poverty, chastity, and obedience. Pilgrimages, however, acts of abstinence, or other self-mortifications, whether of the body or of the will, special prayers or religious exercises, are frequently made the object of vows; and there is another large class of more material objects, as the building of churches, monasteries, hospitals, and other works of public interest or utility, to which mediæval Europe was indebted for many of its most magnificent memorials of piety and of art. Vows in the Roman church law are either "simple" or "solemn." The principal difference between them consists in the legal effects of the "solemn" vow, which, where the subject of such vow is chastity, renders not merely unlawful, but null and void, a marriage subsequently contracted. A "simple" vow of chastity makes it unlawful to marry, but, except in the Jesuit society, does not invalidate a marriage, if subsequently contracted. Catholics acknowledge in the church a power of dispensing in vows; but this is held to be rather declaratory than remissory, and it is not acknowledged in the case of vows which involve any right of a third party. Bishops are held to possess the power of dispensing in simple vows generally; but the power of dispensing in solemn vows and in certain simple vows, as, for example, that of absolute and perpetual chastity, and of the greater pilgrimages, is reserved to the pope. The practical operation of the canon law regarding vows has evidently been much modified, even in Catholic countries, since the French revolution, and the subsequent political changes; but this must be understood to regard chiefly their external and purely juridcial effects. So far as concerns their spiritual obligation, the modern Roman theology recognizes little if any change.

VOWEL. See Letters.

VOX POPULI, VOX DEI. "The voice of the people is the voice of God." A phrase from the Latin, of which the origin is unknown. Sir Wm. Hamilton tried, but without success, to trace the proverb back to Hesiod. Lieber referred it to the election of the bishops by the people in the Middle Ages. William of Malmesbury used it about the year 920 A.D., with regard to St. Odo. The Archbishop of Canterbury took it for a text at the coronation of Edward III. in 1327. It is number 97 in a volume entitled, *Aphorismi Politici ex-Ph. Comenæo, per Lambertum Danarum collecti*, 1609.

VOYSEY, Charles, b. London, 1828; graduated, Oxford, 1851; curate of Hessle, 1852–59; of Craigton, 1860–61; of St. Mark's, Whitechapel, London, 1861; ejected on account of a sermon against endless punishment; vicar of Healaugh, Yorkshire, 1864. In 1865 he published in the *Sling and the Stone*, sermons preached at Healaugh on the atonement, justification, incarnation, and inspiration, which were deemed at variance with the Bible and the 39 articles. The secretary of the archbishop prosecuted him in the chancery court of York minster. From the sentence of condemnation he appealed to the judicial court of privy council, which confirmed the sentence, deprived him of his living, and required him to pay the costs. He afterward preached and lectured in St. George's hall, London, a fund having been raised by men of wealth called the "Voysey establishment fund." His discourses are printed weekly.

VRIHASPATI, or, as the word is written in Vedic works, Brihaspati (from *br'ih*, probably hymn, prayer, and *pati*, protector, lord), is, in Vedic mythology, the guardian of the hymns or prayers addressed by the pious to the gods, and he is therefore considered as mainly instrumental in insuring the efficacy of the sacrifice. In consequence, he is "the first-born in the highest heaven of supreme light," because the prayers reach him first; he is "seven-faced." because his faces are the seven Vedic meters; and he is "attended by all the companies of gods," or "represents all gods," when the sacrifice is performed. Being thus the "first sharer of the offering," he is sometimes also identified with *Agni*. His function of guardian of the hymns being similar to that of a priest and spiritual teacher, he is further represented as a priest of the gods, who himself "celebrates worship;" as "the observer of truth," and as imparting "virtuous instruction." In

the epic and Purânic mythology, Vrihaspati figures especially as preceptor of the gods and R'ishis, and as such he also causes them to perform sacrifices. A new character, however, in which he appears at that period is that of regent of the planet Jupiter; and in the ceremonies performed in honor of the planets, and described in several Purân'as, a special worship is paid him in this capacity.

VR/ITRA. See INDRA.

VUILLAUME, JEAN BAPTISTE, 1798–1874; b. France; member of a family of violin makers. He entered his father's shop, and soon manifested great skill. He settled in Paris in 1818. He imitated old violins by such masters as Stradivarius and Maggini. He is said to have made 3000 violins.

VULCAN (the name is probably connected with *fulgere* and *fulgur*, and may be translated the "bright shining one") was the old Italian god of fire. The various myths in connection with Vulcan prove the great antiquity of his worship. Latterly, the character, attributes and history of the Greek Hephæstus were transferred to Vulcan, and the two thus became identified. According to Homer Hephæstus was the son of Zeus and Hera; later accounts, however, asserting that the latter gave birth to him without any co-operation on the part of her husband. He appears to have been twice violently expelled from Olympus—the first occasion was shortly after his birth, when he was dropped upon the earth by his mother, who was disgusted with his sickly deformity; he was received by the marine divinities, Thetis and Euronyme, with whom he dwelt for nine years. He afterwards returned to heaven, and on interfering in a quarrel between his mother and Zeus, the latter seized him by the leg, and flung him from Olympus. After falling for a whole day, he alighted on Lemnos, where he was kindly received by the Sintians. He afterwards returned to Olympus. Homer makes him lame from his birth, while later writers attribute this defect to his second fall on Lemnos. The popular notion of Vulcan or Hephæstus appears to have been that of a burly, lame, good-natured, awkward god, often made the butt and laughing-stock of his fellows. He had a magnificent palace of his own in Olympus, "immortal, brazen, shining like stars," in which was his workshop, containing an anvil and 20 bellows, which worked at his command. Later accounts locate his workshop in the interior of some volcanic isle, such as Lemnos, Lipara, Sicily, etc., and give him as workmen the Cyclopes, Brontes, Steropes, etc. Many wonderful works of art are ascribed to Vulcan by the ancient poets, and as an artist or artificer, he appears to have been regarded as corresponding in some respects to Athene: both instructed men in the useful and ornamental arts, had the power of healing, etc., and at Athens had temples and festivals in common. In the *Iliad*, the wife of Hephæstus is Charis; while in the *Odyssey*, and in later writers, he is represented as being much tormented by the amours of his frail and charming spouse Aphrodite, with her favorite Ares (Mars). In the earlier statues, his lameness appears to have been indicated; but latterly, he was represented as a full-grown, vigorous man, with a beard. See illus., MYTHOLOGY, vol. X.

VULCAN, a supposed planet which possibly is revolving around the sun within the orbit of Mercury. About a quarter of a century ago Leverrier found certain perturbations in the motions of Mercury which indicated the existence of another body in the vicinity. Such a body could be no other than another planet. Less than three years after Leverrier's announcement Dr. Lescarbault announced that he witnessed the transit of the planet across the sun's disk. MM. Porro and Wolf of Zurich believe they saw it making a transit in 1876, but it has not been observed since. According to Kepler's law its revolution around the sun should be accomplished in about one month; and if it exists, it will probably not escape discovery many years longer.

VULCANISM, a term proposed by Humboldt to include all the evidences of internal heat, such as volcanoes, hot springs, etc.

VULCANITE AND VULCANIZED INDIA-RUBBER. See INDIA-RUBBER.

VULCANO, or VOLCANO, the southernmost island of the Lipari group, in the Mediterranean sea, 12 m. n. of the coast of Sicily. It is 7 m. long, 3 m. wide, and contains the crater of a volcano 1200 ft. high, ¼ m. in circumference and ¼ m. in depth, from which issue sulphurous gases and vapors charged with vitriol, ammonia, etc. The soil is very fertile, producing grain, fruit, and grapes. The islet of Vulcanello, lying off the n. coast, containing 2 craters, is connected with it by a neck of land.

VULGATE is the name of the Latin translation of the Bible, which is the received version in the Roman Catholic church. It must not be confounded with the older Latin translation known as the Itala (see ITALIC VERSION). While Jerome was engaged in correcting the Itala, he conceived the plan of producing a completely new version of the Old Testament, done from the Hebrew text itself. He commenced this labor about 385 A.D., and completed it in 405. He also made an improved version of the Italic New Testament, and the two together received the name vulgate. The discrepancies between the vulgate and the Itala, which had been made from the LXX., were so numerous and important, that the charge of heresy and falsification of Scripture was openly preferred against the translator by Rufinus, and even St. Augustine was doubtful for some time whether this charge might not be true. But gradually it made its way into the church, first in Gaul, then in Rome—chiefly through Gregory the Great—and finally throughout

the west. About two hundred years after Jerome's death, it became the universally received version of the church. Not long, however, did it exist in its pure and unadulterated form. Partly through the influence of the emendated Itala, partly through the manifold general causes of neglect, hastiness, and the rest, which have gone so far spoil almost every ancient MS., the text of the vulgate had become so corrupted, that in 802, Charlemagne commissioned Alcuin to revise it by old MSS. and to compare it with the original texts. This revision, however, to which afterward came other "emendations," in the 11th and 12th c. (by Lanfranc, archbishop of Canterbury, and cardinal Nicolaus respectively), completely changed the original character of the work. Nor did the "Correctoria Biblica" (i. e., certain collections of commentated and revised texts, issued at the period), do much for the improvement of the corrupted MSS. The confusion between the different codices was chiefly remarked, when the Tridentine council, in 1546, first declared the vulgate the authorized version of the Roman church, and decreed the preparation of an authenticated edition. In 1564, the papal chair undertook the task; but not before 1590 did Sixtus V. produce the work. This, however, turned out to be so utterly incorrect and faulty throughout, that the copies were speedily suppressed; and another edition, which appeared in 1592, was prepared under Clement VIII., to which in the next year, 1593, that other edition succeeded, which has since remained the normal edition of the church of Rome, and has been reprinted unchanged ever since. We may add, that the Anglo-Saxon translation of the pentateuch and Joshua, by Aelfric (10th c.), has been made from the Vulgate, and not, as has been erroneously supposed, from the septuagint; and that the vulgate has also been repeatedly translated into Arabic (the Psalms even into Persian) for the use of the Roman Catholics in the east.

VULNED, a heraldic term, applied to an animal, or part of an animal—as, for example, a human heart, wounded, and with the blood dropping from it. A pelican in her piety (see PELICAN) is sometimes described as vulning herself.

VULPIUS, CHRISTIAN AUGUST, 1762–1827, b. Germany; educated at Jena and Erlangen. He was a voluminous writer of dramas, romances, operas, etc. His *Rinaldo Rinaldini, der Räuberhauptmann*, published in 1797, was once famous, and was widely imitated.

VULTURE, *Vultur*, a Linnæan genus of rapacious birds, now forming the family *vulturidæ*, to almost all the species of which the name Vulture is popularly given. The *vulturidæ* have a longer beak than the *falconidæ*, and it is straight at the base, slightly or not at all toothed; the upper mandible longer than the lower, and hooked at the tip, the head generally bare, or covered only with a short down, which in most of the species is the case also with the neck—a ruff or collar or soft feathers surrounding the lower part of the neck, into which the upper part, and even most of the head, can be withdrawn. The legs and feet are large, but the claws are not nearly so large and strong as in the *falconidæ*, and are but slightly hooked. The middle toe is very long. The wings are long, and their expanse consequently great. Vultures have great powers of flight, and many of them soar to a very great height in the air. Their plumage has not the neat and regular appearance of that of the *falconidæ*, but it is dense, and not easily penetrated by shot. Vultures are mostly found in warm climates, and many of them are inhabitants of mountainous regions. They feed on carrion, which it seems to be their office in nature to remove from the face of the earth, that the evil consequences of its corruption may be prevented. They seldom attack a living animal, but they have been seen to sit and watch the approach of death, waiting for their feast. They are not in general courageous birds, and are often put to flight by birds much smaller than themselves; yet, if unmolested, they readily become familiar with the presence of man, and some of them seek their food even in the streets of towns, in which they are useful as scavengers They gorge themselves excessively when food is abundant, till their crop forms a great projection, and sit long in a sleepy or half-torpid state to digest their food. They do not carry food to their young in their claws, but disgorge it for them from the crop. The bareness of their head and neck adapts them for feeding on putrid flesh, by which feathers would be defiled; and they are very careful to wash and cleanse their plumage. The question has been much discussed, whether vultures discern dead animals by the eye, or are attracted to them by the smell. It is certain that they possess great powers both of smell and of vision, and the reasonable conclusion appears to be that both are of service in directing them to their prey. The rapidity with which they congregate to a carcass has been remarked with admiration, and vast numbers have often been seen assembled on a battle-field to devour the dead.

The *vulturidæ* are divided into several genera, of which one, *gypaëtos*, approaches to the *falconidæ* in its characters and habits, having the head feathered, and not always feeding on carrion, but often attacking living animals. The lämmergeier (q.v.) is one of this group. The feet are feathered to the toes, while the other vultures have the tarsi bare.

Some of the most notable species of vultures have already been described, as the condor and the Egyptian vulture. The generic name *vultur* is now restricted to those which have the head and neck without feathers and without caruncles, and a ruff of long feathers or of down at the lower part of the neck. To this genus belongs the

Tawny Vulture or Griffon (*V. fulvus*), found in the south of Europe, the north of Africa, and the west of Asia. It makes its nest on the most inaccessible rocks of high mountains, as in the Alps and Pyrenees, and sometimes in tall forest trees. It is a very large bird, more than four ft. in length. Its plumage is yellowish brown, the quills and tail-feathers blackish brown, the down of the head and neck white, the ruff white. When it has found a carcass on which to feed, it remains on the spot, gorging and torpidly resting by turns, till no morsel remains. This vulture has been seen in England, but only as an accidental visitor. The mountains and forests of the south of Europe, as well as of the north of Africa, and great part of Asia, are also inhabited by the Cinereous Vulture (*V.* or *gyps cinereus*), another large species, which departs from the typical character of the vultures in having the greater part of the neck feathered, and comparatively large and powerful claws. It does not, however, attack living animals. India, Africa, and almost all warm countries, abound in vultures of different species which it is unnecessary to describe. In the southern states of North America is found the Black Vulture (*Cathartes atratus*), there generally known as the Carrion Crow, a comparatively small species, not quite two ft. in entire length, of a deep black color, the head and neck covered with warty excrescences, and a few hair-like feathers. This bird is also very abundant in many parts of South America, where it is called the Gallinazo. Very nearly allied to it, and found in the same regions, is the Turkey Buzzard, or Red-headed Vulture (*Cathartes aura*). These vultures are more or less gregarious, not only assembling where food is to be found, but flying in flocks. They make their nests in hollow trees, and sometimes in the chimneys of deserted houses, or on the roofs of houses. In some of the towns of tropical America, they may be seen in great numbers, perched during the heat of the day on the tops of houses or on walls, asleep, with their heads under their wings. The California Vulture (*Cathartes Californianus*) is the largest rapacious bird of North America, being fully four ft. long, and about ten ft. in extent of wings. It is black, with a white band on the wings. It is found only on the western side of the Rocky Mountains. It much resembles the condor in its habits. See illus., Larks, etc., vol. VIII.

Vyâsa is the reputed arranger of the Vedas (q.v.), and the reputed author of the Mahâbhârata (q.v.), the Purân'as (q.v.), the Brahmasûtras (see Vedânta), and a Dharmas'âstra. According to tradition, he was a son of the sage *Paras'ara* and *Satyavatî*, "the truthful," who was a daughter of king Vasu, and a heavenly nymph, Adrikâ. Another tradition makes him also the father of *Dhr'itarâsht'ra*, *Pân'd'u*, and *Vidura*. On account of his dark complexion, he was called *Kr'ishn'a* (black); and, because he was born in an island (*dvîpa*) of the Yamunâ (Jumna) river, his second name was *Dvaipâyana*. That the immense bulk of literature comprised by the above-named works, and relating to different periods, cannot belong to the authorship of one and the same personage, is no matter of doubt. But the name itself of the individual to whom it is attributed conveys the meaning which must be sought for in some of the legends connected with his history. *Vyâsa* (from the Sanskrit *vi* and *as*, literally, "throw in different directions," hence "distribute") means the person who arranges a subject-matter in a diffuse manner, or the act itself of such a diffuse arrangement, and is often contrasted with *samâsa* (from *sam* and *as*, contract), the act of making a concise arrangement, or of abridging (compare the Greek *omēro-*, from *om* = *sam* = *sun*, and *ar* = *as*). Vyâsa is, therefore, a symbolical representation of the work of generations, as embodied in the Vedas, the Mahâbhârata, and the Purân'as, and of the order which gradually was brought into this literary mass. When, therefore, the Vishn'u-Purân'a speaks of 28 Vyâsas who in the reign of the present Manu arranged the Vedas, it is not impossible that some historical truth may underlie this statement, implying, as it does, a different arrangement of the Hindu scriptures at various times: and that the Mahâbhârata, and the Purân'as too, may have undergone various arrangements and recensions, until they settled down in their present form, sufficiently results from their contents. Regarding the Brahmasûtras, tradition itself seems only loosely to connect their author with the Vyâsa of the forgoing works, for it says that he was in a former life a Brâhman, *Apântaratamas*, who, after having attained final beatitude, "by special command of the deity, resumed a corporeal frame and the human shape, at the period intervening between the third and fourth ages of the present world, and was the compiler of the Vedas." (See Colebrooke's *Miscellaneous Essays*, vol. i. p. 327, Lond. 1837.)

W

W, **THE** twenty-third letter of the English alphabet, "is a letter which performs the double office of a consonant and a vowel." According to the decisive experiments of Prof. Willis (*Cambridge Phil. Trans.* iii. 231), the natural order of the vowels is *i*, *e*, *a*, *o*, *u*, or the reverse; in which the sounds must be understood to be those which prevail on the continent. The sounds, then, of *i* (that is, *ee*) and *u* (that is, *oo*) are the most remote, and the attempt to pass with rapidity from either of these to

the others, more particularly to the other extreme, gives an initial breathing which has the character of a consonant, viz., in the one case, *ee-oo*, or *you;* in the other, *oo-ee*, or *we*. See Key's *Alphabet*. This acute analysis of the articulations denoted by the characters *w* and *y* throws a clear light on the double function they perform as consonants and as vowels. The letter *w*, which originated in the middle ages, is merely one *v* joined to another, as its English name imports. It is peculiar to the English, German, and Dutch alphabets. It would appear, from a variety of phenomena in Latin and Greek, that the Latin *v* or *u*, used as a consonant, as well as the old Greek digamma (Ϝ), were more of the nature of the modern *w* than of the decidedly consonantal English *v* (see U and V). The French having, like the other Romanic nations, no character *w*, express the sound by prefixing *ou* to the vowel; as *oui* (pron. *wee*), Edouard = Edward. In the beginning of proper names they substitute *gu;* e.g., Guillaume = William. The Spaniards also use *gu*, as in the many names compounded of the Arabic *wadi;* e.g., Guadalquivir; but more frequently *hu*, as in Chihuahua (pron. *Chiwawa*). In High-German, which has become classical German, *w* is confounded with *v*, and *v* with *f;* thus, Wellington is pronounced *Vellington*. In London, *w* is substituted for *v*, and *v* for *w* with "a most amusing perversity."

WAA'GEN, Gustav Friedrich, 1794–1868 ; b. Hamburg; studied at Breslau, Dresden, Heidelberg, and Munich; was director of the royal gallery of paintings in Berlin, 1830, and of the portrait gallery of the new museum there, 1832; lectured on the history of art in Berlin, 1844. He published a pamphlet on Egyptian mummies; an essay on Hubert and Jan van Eyck; *Kunstwerke und Künstler in England und Paris; Treasures of Art in Great Britain;* and many other valuable works.

WAAL, The (Lat. *Valis* or *Vahalis*), an arm of the Rhine, thrown off near the village of Pannerden, in the Netherlands; flows thence to Nijmegen, Tiel, Nieuw-St.-Andries, between the Boemmeler and Tieler-waard, and unites with the Maas below fort Loevestein (Luvestein). The united rivers then take the name of the Merewede, which, flowing past Gorinchem and Dordrecht, becomes the Oude, or Old Maas. See Maas.

WA'BASH, a river of the United States, rises in Mercer co., western Ohio, runs w. and s.w. through Indiana, forming the southerly half of its western boundary, on the borders of Illinois, to the Ohio river, 146 m. from its mouth, is 550 m. long, and navigable by steamers at high water 300, and has for its principal branches the Tippecanoe, Big Vermilion, Embarras, and White river—the last 200 m. long.

WABASH, a co. in s.e. Illinois, having the Wabash river for its s.e. boundary; 220 sq. m.; pop. '90, 11,866. Co. seat, Mount Carmel.

WABASH, a co. in n.e. Indiana, drained by the Wabash and other rivers; 430 sq. m.; pop. '90, 27,126. Co. seat, Wabash.

WABASHA, a co. in s.e. Minnesota, bounded on the e. by the Mississippi river, where the bluffs rise 400 ft. high; intersected by the Chicago, Milwaukee, and St. Paul railroad; 540 sq. m.; pop. '90, 16,972. Co. seat, Wabasha.

WABASH COLLEGE, Crawfordsville, Indiana, a non-sectarian institution of higher education for young men only, founded in 1832. In 1897 the alumni numbered 732; the amount of invested funds was $500,000; the value of college equipment, including buildings and apparatus, was $350,000. The college grounds consist of forty acres, beautifully shaded with native forest trees. There are five large buildings devoted to educational work, substantially built of brick with stone trimmings, and containing all modern improvements. There are no dormitories. Three elective courses, classical, philosophical and scientific, lead each to the corresponding degree. The physical, chemical and biological laboratories are fully equipped with valuable apparatus. The collections of the museum are worth over $50,000. The library contains 35,000 volumes, and is adapted to *seminar* work. There are eighteen members of the faculty. President, since 1892, G. S. Burroughs, ph.d., ll.d.

WABAUN'SEE, a co. in n.e. Kansas, having the Kansas river for its n. boundary; 804 sq. m.; pop. '90, 11,720. Co. seat, Alma.

WACE, Robert, an Anglo-Norman poet of the 12th century. Many different versions of his name are given in his own books, as well as in the other books which mention him. He is styled Vace, Wace, Waece, Waice, Waicce, Waze; Gasse, Gaice, Guace, Guazi, Guaze, Guascoe, Gazoe; and again, Wistace, Huistace, Huace. It has been supposed that there were really two poets, the one named Wace or Guace, the other named Wuistace; the one the author of *Le Roman du Rou*, the other of *Le Roman du Brut*. About his Christian name there is even more doubt than about his surname. An old writer speaks of him as Matthew; and it seems that he was first called Robert in the *Origines de Caen*, by Huet, whom subsequent authors have followed.

Wace was born in Jersey, in the reign of Henry I., and it is probable that the date of his birth lay between the years 1112 and 1124. He was taken to Caen as a child, and there he received the early part of his education. He was afterward sent into the neighboring kingdom of France; but he returned to Caen, and having entered into holy orders, became a reading-clerk in the royal chapel there. At Caen it was that he composed his works. Henry II., to whom he dedicated *Le Roman du Rou*, gave him a canonry at Bayeux, apparently about the year 1160. He died in England about the year 1180, certainly before the year 1184.

Five separate works are attributed to Wace; but three are slight, short performances, and it is only necessary to notice the two principal—*Le Roman du Brut d'Angleterre* and *Le Roman du Rou*. The former premises that a certain Brutus, a son of Ascanius, and grandson of Æneas, settled in Britain, and became its first king. The book continues the history of the British kings from Brutus to Cadwallader, who died at Rome shortly before the year 700. It is little more, however, than a literal translation into the French from the Latin of Geoffry of Monmouth (q.v.). This poem seems to have been completed in the year 1155. *Le Roman du Rou* (Rollo) is a sort of history of the dukes of Normandy and of the Norman monarchy in England. Neither of these works has the slightest poetical merit. They are both interesting only as showing the state of the French language in the 12th c., and as supplying occasional facts and social traits to the historian.

WACHT AM RHEIN, Die (The Watch on the Rhine), German Volkslied, words by Max Schneckenburger (1819–1849), music by Carl Wilhelm (1820–1873). The song was written in 1840 when the left bank of the Rhine was threatened by France. The music, which is a part-song for men's voices, was composed and first sung in 1854. During the Franco-Prussian war of 1870–'1, the Emperor gave Wilhelm an annual pension. A monument was erected to his memory in his native town of Schmalkalden. A national monument was designed on the Wacht am Rhein, Johannes Schilling, and unveiled in 1883 by the Emperor, near Bingen. An overture, *Die Wacht am Rhein,* was composed by August Klughart. See Grove's *Dictionary of Music and Musicians;* and *Notes and Queries,* Fourth Series, VI.

WACHUSETT MOUNTAIN, in Princeton, Worcester co., Mass., 16 m. n. of Worcester, 8 m. s.w. of Fitchburg, is 2018 ft. high. From its summit is to be had one of the finest views in New England, including parts of six states. Hotels and boarding-houses have been built near it in the last few years, and it has become a summer resort.

WACKE, a German miners' term, introduced by Werner, to designate a soft variety of trap, that has an argillaceous aspect and a greenish-gray color. It resembles indurated clay, but has been formed of volcanic ashes or mud. It is often vesicular, and when the cavities are filled, it becomes an amygdaloid. It is associated with trappean rocks, and, indeed, often passes into basalt or greenstone.

WACO, city and co. seat of McLennan co., Tex.; at the confluence of the Brazos and Bosque rivers, and on the Missouri, Kansas, and Texas, the St. Louis Southwestern, the San Antonio and Aransas Pass, the Texas Central, and the Waco and Northwestern railroads; 95 miles n.n.e. of Austin. It is the seat of Baylor university (Bapt.), Paul Quinn college (A. M. E.), and Add-Rau Christian university (Disciples), and has a female college, business colleges, college and other libraries, city hospital, electric light and street railroad plants, waterworks supplied from artesian wells, national and state banks, and numerous daily, weekly, and monthly periodicals. The industrial plants include woolen and cotton seed oil mills, cotton compresses, and broom and mattress factories. Pop. '90, 14,445.

WAD, in gunnery, a compressible disk forced home in the barrel after the powder, to confine the latter to the least possible space before its explosion. For great guns, the wad is commonly made of rope; for small-arms, of pasteboard.

WADAY, a Mohammedan kingdom of central Africa s. of the Great Desert, and w. of Darfoor. It is called also Dar Saleyh and Borgoo. The population is between 2,000,000 and 4,000,000. It is generally level, though there are many isolated mountains. From the highland on the e. two streams flow through its valleys; uniting to form the Bahr-el-Gazal, which periodically changes the plain of Fittré into a lake; and the Bahr-Iro, another river, flows n.w. through Waday, from the mountains of Marrah. A desert tract on the e. separates Waday from Darfoor; and on the n. is the mountainous and rocky desert of the Tibboos. The s. portion is better watered and more fertile than the northern. Rice, maize, and other grains, as well as all tropical fruits, are raised.

WADDELL', James, d.d., 1739–1805; b. Ireland; brought in infancy by his parents to Pennsylvania; educated at the classical school of the Rev. Dr. Finley, Nottingham, Md.; became his assistant; taught at Pequea, Penn.; relinquished the study of medicine, and by advice of Rev. Samuel Davies, studied theology; licensed by the presbytery of Hanover, 1761; pastor of churches at Lancaster and Northumberland; removed, 1785, to an estate which he called Hopewell, preaching in various churches for 20 years. Soon after his last removal he became totally blind. His remarkable eloquence is described by William Wirt in the *British Spy.*

WAD'DELL, James Iredell, b. N. C., 1824; entered the navy as midshipman, 1841; lieut., 1855. In 1860 he was on the China station, and successfully conducted an expedition into the interior. In 1861 he resigned his commission and became a lieut. in the confederate navy. He was engaged in the Drury's Bluff action, where the union fleet was repulsed; in 1863 was sent to Europe on "special service;" and in Oct., 1864, took command of the noted cruiser, the *Shenandoah,* which was built at Glasgow; sold to a confederate agent by Liverpool owners, and handed over to Waddell near the Madeira islands. From Melbourne the *Shenandoah* started on a cruise lasting 13 months, in which she captured 38 vessels, and of these destroyed all but six. The cruise lasted until August, 1865, long after the surrender of Lee, and in November

of the same year the steamer was turned over to the British government. Capt. Waddell spent some time in European travel, and on his return to this country entered the Pacific Mail company's service. He d. 1886.

WADDELL, Moses, D.D., 1770–1840; b. N. C., graduated Hampton-Sidney college, Va., 1791; ordained a Presbyterian minister, 1792; established a classical boarding-school at Willington, S. C.; president of the university of Georgia, 1819–29. He was an eloquent preacher and an eminent instructor.

WADDING, Luke, 1588–1657; b. Ireland; studied at the Jesuit college, Lisbon; joined the Franciscans, 1605; ordained and taught theology at the university of Salamanca; accompanied as chaplain the bishop of Cartagena to Rome, 1618, sent to settle the controversy concerning the immaculate conception—an account of which embassy he wrote in a folio volume; founded at Rome the college of St. Isidore, 1625; was procurator of Franciscans at Rome, 1630–34; vice-commissioner of the order 1645–48; was one of the papal councilors to settle the Jansenist controversy. He published *Annales Ordinis Minorum; Scriptores Ordinis Minorum.*

WADDINGTON, William Henry, b. France, 1826, of English parentage; graduated at Cambridge, 1849; became a naturalized citizen of France, and made archæological explorations in Asia Minor in 1850 and 1862, the results of which are described in several books. In 1871 he was elected to the national assembly, supported Thiers, and by him was made minister of public instruction, 1873. He resigned with Thiers and voted with the left-center, or moderate republicans. In 1876 he was elected senator for the department of the Aisne, was again minister of public instruction in the Jules Simon cabinet, and in 1877 became minister of foreign affairs in the Dufaure cabinet; in 1878 was the representative of France at the Berlin conference. He was president of the council, Feb.–Dec., 1879; and ambassador to Great Britain in 1883–93. He d. in 1894.

WADE, Benjamin Franklin, 1800–78; b. West Springfield, Mass., removed to Ohio, 1821; studied law; admitted to the bar, 1828; elected prosecuting attorney of Ashtabula co., 1835; state senator, 1837, and twice re-elected; chosen presiding judge of the third judicial district of the state, 1847; U. S. senator, 1851; re-elected 1857 and 1863. He was a strong opponent of slavery; voted for the repeal of the fugitive slave law, 1852; opposed the Nebraska-Kansas bill of 1854, and the purchase of Cuba. After the election of Mr. Lincoln, 1860, he opposed all compromise between the north and the south; was appointed chairman of the committee on the conduct of the war, and advocated a more vigorous policy, urging a law to confiscate the property of the leading secessionists and emancipate the slaves; reported in 1862, as chairman of the territorial committee, a bill to abolish slavery in all the territories, and prohibit it in all future territories; was elected president of the senate, 1867; was sent, 1871, as one of the commission to San Domingo to report in relation to its annexation to the United States.

WADE'NA, a co. in central Minnesota, consisting of fertile prairies drained by numerous rivers; 540 sq.m.; pop. '90, 4053. Co. seat, Wadena.

WADERS, or Wading-birds, a designation often applied to the whole order of birds *grallæ* (q.v.), or *grallatores,* but really appropriate only to some of them, the more aquatic in their habits, as herons, snipes, and rails.

WADHAM COLLEGE, Oxford. In the year 1610, James I. issued a license to Dorothy Wadham, acting as executrix of the will of her deceased husband, Nicholas Wadham, esq., to found a "college of divinity, civil and canon law, physic, good arts and sciences, and the tongues." Dorothy Wadham purchased the site and ruins of the priory of the Austin friars, in the suburbs of Oxford, and built the present college for a warden, 15 fellows, 15 scholars, and 2 chaplains. The fellows were formerly elected from the scholars, and the tenure of the fellowships was limited to 22 years; nine of the scholarships were limited to certain counties, and to the founder's kin. By the commissioners under 17 and 18 Vict. c. 81, the fellowships and scholarships were thrown open—the former to all persons who had passed the examinations for a B.A. degree; the latter to all persons under 20 years of age. The commissioners also abolished the limitations on the tenure of the fellowships. At present, the number of fellowships is fourteen, one of them having been appropriated to the professor of experimental philosophy. The scholarships are worth £80 a year, besides rooms, and are tenable for five years.

WADHAMS, Edgar P., b. at Lewis, N. Y., 1817. He graduated in 1838 at Middlebury, Vt.; entered the priesthood of the Protestant Episcopal church, but in 1850 entered that of the Roman Catholic church. In 1872 he was consecrated bishop of Ogdensburg, N. Y. He d. in 1891.

WA'DI, an Arabic word signifying a river, a river-course, a ravine, or valley. It is supposed that the Greek *oasis* is a corruption of *wadi.* It is of frequent occurrence in the names of places; e.g., Wadi-Musa (i.e., the valley of Moses) in Arabia. In Spain, where most of the rivers bear names given them by the Arabs, *wad* has been transformed into *guad;* e.g., Wadi-l-abyadh (the white river) has become Guadalaviar.

WADLEIGH, Bainbridge, b. Bradford, N. H., 1831; received an academical education; was admitted to the bar, 1850; was a member of the state legislature, 1855–56, 1859–60, 1869–72; was elected U. S. senator, as a repub., serving, 1873–79. He d. 1891.

WADSWORTH, BENJAMIN, D.D., 1669–1737; b. Mass.; graduated at Harvard college, 1690; was associate pastor, with Mr. Foxcroft, of the First church, Boston, 1696–1725; elected president of Harvard college, 1725. He published sermons and theological treatises.

WADSWORTH, JAMES, 1730–1817; b. Conn.; graduated at Yale college in 1748. He was town clerk of Durham, Conn., 1756–86; became a brig.gen. in the continental army in 1776; was a member of the Conn. committee of safety, and had charge of the defense of the Connecticut sea-coast in 1777. In 1777 he was appointed maj.gen. in the Conn. militia. He was afterward judge of the New Haven county court of common pleas, and a member of congress, 1783–86.

WADSWORTH, JAMES, 1768–1844; b. N. Y.; graduated at Yale college, 1787; purchased with his brother a large tract of land in the Genesee valley, 1790; became one of the wealthiest land owners in the state; was much interested in education, and at his own expense printed and circulated pamphlets, employed lecturers, and offered premiums to the towns which established school libraries; advocated as early as 1811 the formation of normal schools, and was instrumental in founding the state normal school; founded and endowed an institution and library at Geneseo for scientific lectures. In the sale of his lands he stipulated that two tracts of 125 acres each in every township should be free for a church and a school.

WADSWORTH, JAMES SAMUEL, 1807–64; b. N. Y.; studied at Hamilton and Harvard colleges; having studied law, he assumed the care of the family estates; was made brig.gen. of volunteers in 1861, and military governor of Washington city, 1862; participated in the battle of Fredericksburg; at Gettysburg his division was the first to engage the enemy, and through the day lost 2,400 out of 4,000 men; during the second and third days' fight maintained the heights on the left of the line. In the Richmond campaign of 1864 his division crossed the Rapidan May 5, and in the evening suffered severely in a conflict of several hours. On the following day he was struck in the head with a bullet and died Sunday, May 8.

WADSWORTH, PELEG, 1748–1829; b. Mass; educated at Harvard, and went into business. Entering the continental army as capt. of a company of minute-men, he was aid-de-camp to Gen. Ward, adjt.gen. of Massachusetts, and in 1777 appointed brig.gen. He was captured on the Penobscot expedition, where he was second in command. Settling in Maine in 1784, he was a state senator in 1792, and member of congress, 1793–1806. The government granted him a large tract of land for his services.

WAFER, in relation to the Roman Catholic usage of the eucharistic communion, is the name given (chiefly by non-Catholics) to the thin circular portions of unleavened bread which are used in the Roman church in the celebration and administration of the Eucharist. In ancient times the bread and wine for the Eucharist were contributed by the faithful; and a place is found in the eucharistic service of every known liturgy for this offering, still known by the name of offertory (q.v.). But in the Latin church, for many centuries, the bread (which, as being unleavened, and different from that in common use, needed special preparation) has been provided by the clergy; and the practice has been followed of preparing it in the form of thin cakes, commonly, although not necessarily circular, and frequently impressed with sacred representations or emblems, as the crucifixion, the lamb, the Christian monogram, the cross, and other sacred symbols. The circular form itself is by some ritualistic writers regarded as symbolical, the circle being a figure of perfection. The wafers used in the Roman Catholic church are made of different sizes, the smallest about an inch in diameter for the communion of the people, a second considerably larger for the celebration of the mass, and a third still larger to be placed in the monstrance (q.v.) for the service of benediction or exposition. See LORD'S SUPPER.

WAFERS, thin disks of dried paste, mostly colored, used for sealing letters, or for attaching papers together. They are made by mixing fine wheaten flour with water and any non-poisonous coloring materials, so as to form a mixture not thicker than thin cream. A small quantity of this is poured on the lower limb of a pair of wafer-irons, which are formed like a pair of pincers, but with flat blades about 12 in. long by 9 in breadth, the inner surface of which is kept well polished. Before being used they are heated over a charcoal or coke fire, and the liquid paste being poured on the lower blade, the pressure of the two blades distributes it equally in a thin sheet between them, the superfluous material being squeezed out at the sides, from which it is shaved off by means of a knife. In a few seconds of time, if the blades are hot enough, the sheet of paste becomes dry and half baked. The sheets so formed are then stamped out into disks of the sizes required. Formerly, wafers were very extensively used, and their manufacture was one of considerable importance; but the introduction of gummed envelopes has almost driven them out of use.

WA'GENINGEN, an old but well-built t. in the Netherlands, province of Gelderland, is situated near the Rhine, to which access is had from it by a canal. Pop. 8000.

WAGER-POLICY, in insurance, is a policy in which the insured has no insurable interest. Such insurance contract is void in law as contrary to public policy.

WAGERS, in the United States, have generally been held void if immoral, indecent, tending to restrain marriage, or (as given in a Pennsylvania decision) if relating to the

age, height, weight, wealth, situation, or circumstances, of any person; also, any likely to interfere with the exercise of the elective franchise. Many states have statutes making all wagers null and void, and in others an elector is disqualified either by statute or by constitutional provision from casting his vote at an election in regard to which he has made a wager. Even when legal, the stakeholder's authority may be rescinded by either party before the event, and the money recovered by trover or assumpsit actions.

WAGES, in a general sense, are the compensation for labor, in a more restricted sense they are the compensation for labor carried on under the direction of another. It is in this latter sense that political economy uses the term, profits being the remuneration which a man receives when working for himself, that is, not under the direction of an employer, while wages always imply the existence of an employer. It is a general feature of wages that they are paid at short intervals, as being necessary for immediate support, and the term proletariat is often applied to those who receive this sort of remuneration, that is, who live during a given week on the proceeds of that week's labor.

Wages, in the modern sense of the word, were not present in the middle ages. Under the feudal régime, protection by his lord and certain privileges on the land which he worked were the only remuneration of the laborer, except in the case of those artisans who took refuge in cities and laid the foundation of the burgher or middle class. Even there the remuneration of the workman was in no wise subject to the present law of wages, for his pay was under the complete control of the guild to which he belonged, and not affected by competition to any such extent as wages are at present. So long as the guild system lasted, the wages problem in its present form did not exist, and even after the guild system was abolished, governments paid a strict attention to the laboring class, regulating what price he must ask for his services, where he must live, and under what conditions he might change his residence. Just as the economic policy of the times (see POLITICAL ECONOMY) fettered trade, so it imposed every imaginable restraint on labor, without regard to that principle maintained by later economists that labor, if left to itself, would naturally seek its most productive channel. It took the forcible arguments of Adam Smith to convince statesmen that restraint of labor, like restraint of trade, checked economic advancement.

After Adam Smith came the so-called orthodox school of economists, with their firm belief in the efficacy of natural law and in the desirability of absolute freedom of contract between masters and men. They opposed everything which tended to impede the free play of natural laws. Out of their reasonings grew the doctrine of the wages fund. The chief points of this are, that there is a certain fund set apart by economic forces for the payment of labor. During a certain period of time no power on earth can change this fund. If the share of the wage earner exceeds it, it must be at the expense either of the share of the capitalist, or of the share of the landlord. Yet the share of the capitalist at any given time is just enough to turn the requisite amount of wealth into capital, and the share of the landowner is just enough to keep the requisite amount of land under cultivation. If there is a falling-off in either, it must be because either one or the other of these factors of production have had to forego their just due, and the result must be, in such an event, the impairment of productive power to the detriment of the laborer as well as to that of society as a whole. The only means by which the individual laborer can secure a larger share of this wages fund, is by maintaining a higher standard of life, and refusing to increase his numbers beyond a certain point, that is, beyond a point at which his share of the fund is sufficient to supply his needs according to that standard. Yet the same writers who taught this doctrine of the wages fund, showed that there is always a tendency for the number of laborers to increase up to the limit of bare subsistence. The outlook for the wage earner on these assumptions was gloomy, and the socialistic writers arrived, by the logic of the old school of economists, at the conclusion that free competition was a failure, and that a radical reorganization of society was necessary. The economists accordingly began to reconsider their premises. An Englishman named Thornton exposed the fallacy of the wages fund doctrine, and John Stuart Mill, who had been one of its ablest advocates, publicly recanted.

The wages fund theory is not generally held at present. The objection to it is that there is no ground for assuming the existence of a fixed fund. Wages may be paid out of product. A recent writer goes so far as to say that wages are the discounted value of the product. Of course it usually happens in a business that an employer has a certain amount at any given time intended for the payment of his workmen, but there is no reason for considering this sum fixed, because as fast as it is diminished, the value of the work done by his laborers can be made to replenish it. So far from being a fixed fund, it varies always from day to day, since at the end of each day the employer is richer to the extent of the value which the labor of his workmen has added to the materials upon which it is engaged.

This view of wages as coming in reality out of the product of industry, has made an important change in the economic theory of the relations between labor and capital. If the laborer is paid according to the value he creates, it is obvious that his share may be increased without trenching upon the share of the capitalist or of the employer. Some economists hold that the principles which underlie the rent of land (see RENT) also underlie the remuneration of labor, on the assumption of perfect competition, that is to say, just as the rent of land arises from differences in fertility and situation, so compensation of labor springs from differences in industrial efficiency or in advantage. As one piece of land

of superior fertility yields a surplus as compared with a piece of land of inferior grade, so labor of the more capable or industrious workman yields a greater return than that of a less efficient laborer. The importance of this is that, theoretically, under a system of perfect competition, it is conceivable that the share of the wage earner may be obtained without subtracting from the shares of the other factors of production. The view of the socialists is that the wages system is merely transitional, and that just as slavery and serfdom have passed away, it too will pass away through the process of evolution, although human efforts can aid in bringing this about. As a rule, the socialists attach too little importance to the share of business ability and skill in management as factors of production, holding that labor is entitled to the product of industry without regard to the claims of the other elements in production.

To pass from the theoretical to the practical side of the wages question, the historical fact is that for the first three hundred years of the period during which the modern system of free competition has existed, wages tended to decline, but during the succeeding sixty years, i. e., from about 1840 to the present time, they have increased. The fact of this increase during the last sixty years is generally admitted. The opponents of the system of free competition say that the increase is nominal and not real, that it is wholly due to the depreciation in the value of money. It is true that the value of the precious metals has declined, especially since the discovery of gold in California, in 1850, but the decline has not been sufficient to offset the increase in wages, and, while double the amount of money will not purchase double the amount of goods that it would purchase sixty years ago, it will still buy nearly two-thirds more, so the general conclusion is that wages have increased not only nominally but really. It seems strange, at first thought, that during the very period in which competition has been keenest and in which capital has gained the advantage of greater concentration, the condition of the laborer should have improved. This is explained by the fact that in the earlier period, while capital was in the control of more persons, and therefore subject to more competition than at present, labor was wholly unorganized. The parties in the industrial struggle, that is, the capitalist-employers on the one hand and the laborers on the other, were far more unevenly matched at the beginning of the nineteenth century than they are at its close. The advantage was greatly on the side of the capitalist, and the result was a more unfair distribution of wealth than at present, for now labor too is organized, and instead of a miscellaneous crowd of individuals competing for employment, we have unions and federations of labor enforcing their demands by strikes and boycotts. In other words, organized labor is pitted against organized capital. The consequences of the contest are more serious to the community than before, and for this reason the motive for amicable adjustment is greater.

As to the movement of wages in the United States in the past two hundred years, the figures show that the wage rate has steadily increased. Carroll D. Wright finds that at the close of the colonial period, agricultural laborers received 40 cents a day, butchers $33\frac{1}{3}$ cents, carpenters 52 cents, shoemakers 73 cents, and boat-builders 90 cents. It is hard to estimate the purchasing power of money at that time, but it would seem that while meats, dairy products and house rent have increased in the United States as well as in Europe, other commodities have decreased in as great proportion. Manufactured goods have, of course, cheapened considerably and there has been a cheapening along such lines as may be classed under the head of transportation, intercommunication and education. The estimates of the comparative purchasing power of wages are very diverse. In the United States they seem to show that a dollar will purchase more now than it would one hundred years ago, while in Europe it is probable that the present purchasing power of money is less than at the beginning of the nineteenth century. One of the best estimates of comparative wages in the United States was made by the Senate Committee on Finance in its report on *Wholesale Prices, Wages and Transportation*, in 1891. In order to indicate the general course of wages, they compared those paid in twenty-two industries, including about one hundred establishments, in 1860, with those paid in the same industries in 1840 and in 1891 respectively. Placing the average paid in 1860 at 100%, they found that wages in 1840 stood at $87\frac{7}{10}$ and wages in 1891 stood at $160\frac{7}{10}$, that is to say, that wages had increased 73% as compared with 1840, and 61% as compared with 1860.

While this increase has been general in all civilized countries, the fact remains that the increase of the other factors in production has been more than proportional. It is the complaint of the socialists that the wage earner has been forced to see others gaining more than their proportion and that this excess must have been taken from his share. The French economist Gide estimates that the total of all private fortunes in France has trebled in fifty years and more than doubled in thirty years, while the most optimistic estimates of the laborers' share do not exceed 100% and most of them are not above 66%.

The practical questions connected with the study of wages are so numerous that it is impossible to deal with them within the limits of this article. Among the most important of these questions are the extent of unemployment and the means adopted for its relief, the effect of trade unions, the utility of the various forms of co-operation, the future of unskilled labor, the effects of strikes, the increase in the number of female employees, and the relation of production to productive capacity. For much valuable information on these and kindred topics relating to recent conditions in the United States the reader is referred to the publications of the United States Department of

Labor and of the Bureaus of Labor of the several states. The following table, from the Bulletin of the Department of Labor of May, 1897, gives some interesting statistics of the number of wage-earners in the United States, its increase from 1870 to 1890, and the comparative number of male and female laborers:

NUMBER OF MALES AND FEMALES 10 YEARS OF AGE OR OVER IN THE UNITED STATES AT THE CENSUSES OF 1870, 1880, AND 1890, BY CLASSES OF OCCUPATIONS.

CLASSES OF OCCUPATIONS.	1870.		1880.		1890.	
	Males.	Females.	Males.	Females.	Males.	Females.
Agriculture, fisheries, and mining	5,744,314	397,049	7,409,970	594,654	8,333,813	679,523
Professional service	278,841	92,257	425,947	177,255	632,646	311,687
Domestic and personal service	1,338,663	973,157	2,321,937	1,181,506	2,692,879	1,667,698
Trade and transportation	1,209,571	19,828	1,803,629	62,852	3,097,701	228,421
Manufacturing and mechanical industries	2,098,246	353,997	2,783,459	630,890	4,064,051	1,027,242
All occupations	10,669,635	1,836,288	14,744,942	2,647,157	18,821,090	3,914,571

WAGNER, ADOLF, b. 1835, German economist, one of the ablest of the so-called historical school of political economists (see POLITICAL ECONOMY), was educated at Göttingen and Heidelberg, became professor of statistical science at Dorpat in 1865, of political science at Freiburg in 1868, and at Berlin in 1870. After publishing several works on monetary and financial topics, he undertook, in collaboration with other economists, an exhaustive and lengthy treatise on political economy, of which the first volume (*Grundlegung*) appeared in 1876, and the seventh volume (*Finanzwissenschaft*, Part III.) in 1889. He had already discussed social theories and the claims of socialists in his well known work *Ueber die Socialen Frage* (1872), and in the longer treatise includes a careful critical study of scientific socialism, especially as expounded by Rodbertus and Marx. In this he showed himself favorable to an enlargement of state functions, supporting vigorously, for instance, state control of railways and insurance, and ranged himself with the so-called *Kathedersocialisten*, or "socialists of the chair." His position on these questions involved him in controversy, and a record of one of these economic tilts is given in *Mein Konflikt mit dem Freiherrn von Stumm*, which he published in 1895. Among other later writings of his are *Die Neueste Silberkrisis und Unser Münzwesen* (1893), and several articles in Schönberg's *Handbuch der Polit. Oekonomie.*

WAGNER, CHARLES, a French writer, born January 3, 1852. At the age of 14 he was sent to Paris, and afterward studied theology at the University of Strasburg and at Göttingen. He has had parishes in Protestant missions in various parts of France and has lived in Paris since 1882. He has published *Youth* (1893) and *Courage* (1894), both of which works have been translated into English; and *La Vie Simple.* These books are a protest against the decadent spirit of modern France, and are marked by a high moral and spiritual tone.

WAGNER, RICHARD, the greatest of modern composers, b. in Leipsic, May 22, 1813; d. in Venice, Feb. 13, 1883. His ancestors were natives of Saxony, of respectable position, and his father, Carl Friedrich Wilhelm Wagner, was clerk of the police court in Dresden, and a passionate lover of the theatre. He died when Wagner was a few months old, and his mother was married two years later to Ludwig Geyer, dramatic author and actor, who settled in Dresden and entered Wagner in the Kreuzschule under the name of Geyer. Geyer wished to make a painter of him, but Wagner's first passion was for poetry, and at the age of thirteen he translated the first twelve books of the Odyssey out of school hours, and wrote several tragedies. In 1827 he entered the Nicolaischule, but, angry at being placed in the third class, shirked his studies and spent his time in writing dramatic poetry. His attention was first attracted seriously to music by hearing Beethoven's symphonies at the Gewandhaus, and he tried to study harmony alone. Gottlied Müller taught him music, and under his guidance Wagner wrote a quartet, a sonata, and an aria, but Müller considered him willful, and Wagner thought him a pedant. In 1829 he went to the Thomasschule in Leipsic, but studied in a desultory way, and an overture was performed and failed. In 1830 he entered the University of Leipsic as a student of philology and æsthetics, but neglected these for a course of composition under Theodor Weinlig. A symphony in C was given at the Gewandhaus, Leipsic in 1833, in which year his career begins. He was engaged as chorus-master at the Stadttheater in Würzburg, where his elder brother Albert was actor and stage-manager. Here he wrote his first opera, *Die Feen*, after Gozzi's *La donna serpente*, but this work was not represented until 1888. In 1834 he went to Magdeburg, as music-director of the Stadttheater, where he wrote his *Das Liebesverbot* on Shakspeare's *Measure for Measure*, which was disastrous. In 1834 he married the actress Wilhelmine Planer and followed her to Königsberg, where he became engaged at the theatre, remaining until 1837, when he went to Riga in the same capacity. Here he wrote the text and part of the music of *Rienzi*. In 1839 he set sail for Paris by way of London, and while on the voyage conceived the idea of the *Flying Dutchman* (*Der fliegende Holländer*). Arriving in Paris, he worked hard to get his operas, *Das Liebesverbot* and *Rienzi*, accepted at the Académie Royale de Musique, but was unsuccessful, and after three years of poverty and disappointment, he went to Dresden, where Rienzi was represented in 1842 with such success that Wagner was made Hofkapellmeister with Reissiger. *Der*

fliegende Holländer and *Tannhäuser* followed, and *Lohengrin* was shelved owing to Wagner's participation in the revolution of 1849. Exiled by the government, he fled to Weimar to Liszt, with whom he had formed an ardent friendship, and thence to Zürich, where he wrote his most important pamphlets, *Die Kunst und die Revolution; Das Kunstwerk der Zukunft; Kunst und Klima; Oper und Drama;* and *Eine Mittheilung an meine Freunde,* besides the entire text and part of the music for the *Nibelungen Trilogy.* In 1857 he tried to gain a representation for his newly completed opera, *Tristan und Isolde,* and in 1860 went to Paris, hoping to have this, or *Tannhäuser,* or *Lohengrin,* represented in French, but was unsuccessful. He gave three concerts of excerpts from his works at the Theatre Italien, which created great excitement and controversy. Owing to the Princess Metternich, Tannhäuser was accepted at the opera, and given in 1861, but it was soon withdrawn. In this year Wagner received permission to return to any part of Germany except Saxony. *Tristan und Isolde* was accepted in Vienna, but was given up after seven rehearsals. In 1862 Wagner lived at Biebrich on the Rhine, working on *Die Meistersinger.* In 1864 he was invited by Ludwig II. to Bavaria, and given by him a villa on Lake Starnberg and a yearly stipend. In 1865 *Tristan und Isolde* was given under von Bülow's direction in Munich, and *Die Meistersinger* in 1868. From 1865 till 1871 Wagner lived at Triebschen on the Lake of Lucerne. His wife died in 1866, and in 1870 he married Liszt's daughter, Cosima, who had been divorced from Hans von Bülow.

King Ludwig planned to build a special theatre for Wagner in Munich, but the site was afterwards chosen in Bayreuth, where Wagner settled in 1872, and on his sixtieth birthday the corner-stone was laid. In August, 1876, the dream of his life was realized by the festival performance of the *Nibelungen Trilogy,* under the direction of Hans Richter. This was one of the greatest events in the history of music. No expense was spared to secure the most celebrated artists, and the orchestra was composed of distinguished musicians, including August Wilhelmj, as first violin. Performances of Wagner's music dramas have been since given annually with the exception of a few years. Wagner's last work, *Parsifal,* was brought out there in July, 1882. Afterwards Wagner went to Venice, where he died. On Feb. 13, 1883, his body was taken to Bayreuth and interred in a vault in his garden at "Wahnfried." Wagner was slightly under middle height and quick in movement, speech, and gesture.

"The fascination of his talk and his ways increased on acquaintance. When roused to speak of something that interested him he looked what he meant, and his rich voice gave a musical effect to his words. His presence in any circle apparently dwarfed his surroundings. His instinctive, irrepressible energy, self-assertion, and incessant productivity went hand in hand with simple kindness, sympathy, and extreme sensitiveness. . . . The noble and kindly man, as his friends knew him, and the aggressive critic and reformer addressing the public, were two distinct individuals. Towards the public and the world of actors, singers, musicians, his habitual attitude was one of defiance. He appeared on the point of losing his temper, showed impatience and irritation, and seemed to delight in tearing men and things to pieces. His violence often stood in the way of his being heard; indeed he has not yet been heard properly, either on questions of art so near and dear to him, or on questions further off regarding things political, social, or religious." . . .

"A list of the principal books in the extensive library at Bayreuth would give a fair idea of his literary tastes, for he kept nothing by him that was not in some way connected with his intellectual existence. The handiest shelves held Sanskrit, Greek, and Roman classics; Italian writers from Dante to Leopardi; Spanish, English, French dramatists; philosophers from Plato to Kant and Schopenhauer; a remarkably complete collection of French and German mediæval poems and stories, Norse sagas, etc., together with French and German philologists; history and fiction, old and new, were represented, and translations of Scott, Carlyle, etc."

His favorite musical works were: Beethoven's quartets, Sonatas, and Symphonies; Bach's *Wohltemperirtes Clavier;* Mozart's *Zauberflöte, Entführung aus dem Serail, Figaro,* and *Don Juan;* Weber's *Freischütz* and *Euryanthe;* and Mozart's Symphonies in E-flat, G minor, and C.

Wagner's aim has been defined as "reform of the opera from the standpoint of Beethoven's music." His argument is that in our day "each separate branch of art has reached its limit of growth, and cannot overstep them without incurring the risk of becoming incomprehensible, fantastic, absurd. At this point each art demands that it shall be joined to a sister art—poetry to music, mimetic to both; each will be ready to forego egotistical pretensions for the sake of an artistic whole, and the musical drama may become for future generations what the drama of Greece was to the Greeks." Wagner's principal critical work, *Oper und Drama,* contains a quasi-historical criticism of the opera; a survey of the spoken drama; and an attempt to construct the theory of the musical drama. His Beethoven is a study of the metaphysics of music based on Schopenhauer, and his other essays are valuable for their wide range and minute analysis. In his early years the choice of subject gave him much concern, but he finally found his field in the ancient myths, but only those who are familiar with the sources of Wagner's dramas can justly appreciate the amount of thought and work that was required to select, arrange, and weld the material together. Many of his poems are written in

alliterative verse. When the poem was finished the music was written. With the first conceptions of characters and situations, certain musical phrases had suggested themselves, and these were worked out into the *leit-motive*, which in Wagner's hands are manipulated with great skill. They are woven in and out of the orchestral score like visions, recalling the past, floating the action, accenting the detail, and clearing all mysteries like a Greek chorus. Wagner is the supreme master of instrumentation. His orchestra is fuller and richer than that of Beethoven, which is due to his elaborate treatment of the string-quartet, the frequent sub-divisions of the various groups of instruments, the use of chromatics in horns and trumpet, and the addition of many instruments unknown to Beethoven. He frequently supplements certain parts in the wood-wind and brass, with other instruments of their family, producing unique and beautiful effects. Wagner's chromatic and enharmonic progressions are often made by passing notes which have melodic significance only, but serve to bind the various *leit-motives* together. The harmonic framework of the dramas with the gigantic scheme of rhythms, harmonic combination, and *leit-motives* must be studied in order to understand the dramatic action, for the orchestra is, in fact, a huge caldron, which may be regarded as brewing all that transpires upon the stage. Nothing greater that the ride of the Walküre and the *Waldweben* in Siegfried in the way of tone-pictures has ever been written.

Wagner's works for the stage are: *Die Hochzeit*, fragment (1833); *Die Feen*, overture only performed, Magdeburg (1834); *Das Liebesverbot*, Magdeburg (1836); *Rienzi*, tragic opera, Dresden (1842); *Der fliegender Holländer* (*Flying Dutchman*), Dresden (1843); *Tannhäuser* (1845); *Lohengrin*, Weimar (1850); *Rheingold*, Munich (1869), and *Die Walküre*, Munich (1870), performed with *Siegfried* and *Die Götterdämmerung* as *Der Ring des Nibelungen*, Bayreuth (1876); *Tristan und Isolde*, Munich (1865); *Die Meistersinger von Nurnberg*, Munich (1868); and *Parsifal*, Bayreuth (1882). Orchestral music: Eight overtures, including *Eine Faust Ouverture;* Symphony in C; *Huldigungsmarsch* (1864); *Kaisermarsch* (1871); *Grosser Festmarsch*, for the Centennial, Philadelphia (1876); *An Weber's Grabe: Trauermarsch*, and double vocal quartet (1844); *Siegfried Idyll* (1870); and *Das Liebesmahl der Apostel* (1843). Choral works: *New Year's Cantata*, Magdeburg (1835). Pianoforte music: Sonata in B-flat; Polonaise in D; Fantasie in F-sharp minor; *Albumblätter* (Album) *Sonata* in E-flat; songs and arrangements for the pianoforte of Beethoven's *Ninth Symphony*, Mozart's *Don Juan*, Glück's *Iphigenie en Aulide*, Palestrina's *Stabat Mater*, Donizetti's *La Favorita*, and *Elisire d'amore* and Halévy's *La Reine de Chypre* and *Le Guittarero*. Wagner's literary works are contained in ten volumes entitled *Gesammelte Schriften* (Leipsic, 1871–85), and in *Nachgelassene Schriften und Dichtungen von R. W.* (1895). Dannreuther has translated *Music of the Future* (London, 1873); *Beethoven* (1880); and *On Conducting* (1885); and Hueffer the *Letter on Liszt's Symphonic Poems* (London, 1881). See A. Jullien, *Richard Wagner, sa vie et ses œuvres* (Paris, 1886); Glasenapp, *Richard Wagner's Leben und Wirken* (Leipsic, 1882); do., *Wagner-Lexicon* (Stuttgart, 1883); Kastner, *Wagner-Catalog, 1830–83* (1872); Oesterlein, *Katalog einer Wagner Bibliothek* (1882); Mayrsberger, *Die Harmonik Richard Wagners* (Chemnitz, 1882); R. Hagen, *Tannhäuser und Lohengrin* (Berlin, 1873); *Bayreuther Blätter;* Liszt, *Gesammelte Schriften;* H. von Wolzogen, *Erinnerungen an Richard Wagner* (Vienna, 1883); do., *Richard Wagner's Lebensbericht* (Leipsic, 1874; translation in *North American Review*, 1879); do., *Poetische Lautsymbolik* (Leipsic, 1876); do., *Der Nibelungen Mythos in Sage und Literatur* (Berlin, 1876); Ehrlich, *Für den Ring der Nibelungen gegen das Festspiel in Bayreuth* (Berlin, 1876); Julius Stinde, *Meistersinger Motive* (Hamburg, 1873), and *Briefwechsel zwischen Wagner und Liszt* (Leipsic, 1887), translated by Heuffer, *Wagner-Liszt Correspondence* (New York and London, 1889).

WAGNER, Rudolf, 1805–64, German physiologist, studied medicine at Erlangen and Würzburg, and completed his education at Paris, where he studied comparative anatomy. After travelling in France, he visited Cagliari, but returned to Germany, and for a short time practiced medicine at Augsburg. He then taught in the university of Erlangen, where he became a professor in 1832. In 1840 he was called to the university of Göttingen. Among his writings are *Lehrbuch der Vergleichenden Anatomie* (1834–35), republished under the title of *Lehrbuch der Zoötomie* (1843–47); *Icones Physiologicæ* (1839–40); *Lehrbuch der Physiologie* (1839); *Handwörterbuch der Physiologie* (1842–55); and *Neurologischen Untersuchungen* (1854).

WAGON, a vehicle for the conveyance of goods or passengers, is mounted on four wheels, but varies considerably in the construction of its other parts, according to the

species of the traffic in which it is to be employed. Since the wagon has four wheels, it is quite unnecessary that any part of the weight should be sustained on the shafts, and accordingly these latter are hinged to the fore-part of the frame, so as to be raised or let down at pleasure. Most wagons are mounted on springs, on account of the weight of the vehicle, and the absence of the steadying weight of the horse, owing to the shafts not being immovably attached to the frame. For facility in turning, the fore wheels are occasionally smaller than the hind ones; and in addition, the fore axle of the lighter kinds of wagon is attached to the body of the wagon by a swivel-joint, the shafts or pole being in this case attached to the fore axle; but the diminution of the size of the wheels is open to grave objection, on account of the greater friction. It being almost impossible for the beasts of draught to control and subdue the momentum of a heavily-loaded wagon descending a slope, it is necessary to employ a drag of some sort; the rudest forms of which are a thick cylinder of tough wood inserted between two spokes of the wagon which, being carried upward in the wheel's revolution, is "jammed" against the under side of the wagon-frame, and stops the wheel's rotation; and the *chain-drag*, which was merely a chain firmly fastened at one end to the wagon-frame between a fore and a hind wheel, and furnished at the other end with a large hook, to hold the tire of the hind wheel; the method of chaining the fore and hind wheels together was also employed. But in the better class of wagons, the *shoe* and *break* (see DRAG) are now employed. Various forms of wagon in use in foreign countries are the brewer's *dray*, the railway *lorry*, the agricultural *wain* (in common use in England and on the continent), and the *bullock-cart* of s. Africa. In the U. S. the large Conestoga wagon, or "prairie schooner," covered with canvas and drawn sometimes by several yoke of oxen, figures in all stories of emigrant and pioneer life, and is still used in the far west. The "Concord wagon" is largely used for mountain travel, and the heavy Studebaker wagon, for farm work. The comparative merits of a vehicle in which the horse has merely to draw, and one, as the cart, in which he has to carry as well as draw, have often been discussed, though never sufficiently tested; but it seems to be generally believed that, despite the distress arising from his confined position in the comparatively immovable shafts of a cart, a horse can transport a greater weight to a moderate distance by the same exertion of muscular force in a cart than in a wagon.

WA'GRAM, or DEUTSCH-WAGRAM, a village of lower Austria, on the left bank of the Russbach, 19 m. n.e. from Vienna, is of little importance, except as the site of the great battle between the French and Austrians in the campaign of 1809, which forced Austria to bow before Napoleon, and submit to the onerous conditions of the fourth treaty of Vienna (q.v.). After the capture of Vienna, Napoleon resolved to pass the Danube, and complete the prostration of Austria's military strength by the destruction of her last army—that under the archduke Charles; and with this view, he called in the Italian army, under Eugene Beauharnois, and all his outlying corps, concentrating them in and about the island of Lobau; and after a few feints, calculated to mislead the archduke, who, stationed on the n. bank, was vigilantly guarding the various crossings, succeeded in effecting a most extraordinary passage, on the morning of July 5, 1809, from the island of Lobau to the n. bank, opposite Enzersdorf, landing 150,000 infantry, 30,000 cavalry, and 600 pieces of cannon before six in the morning. When the morning light showed the Austrians how they had been out-maneuvered, they retreated across the plain of the March-field to its northern extremity, and took up a formidable position at Wagram, and being closely followed up, were, on the evening of July 5, attacked by a part of the French army. By the vigorous exertions of the archduke in person, the assailants—after a temporary success—were completely repulsed, and the Austrians, exulting in their second victory over Napoleon, waited in sanguine expectation the events of the next day. In the morning, the archduke resolved to assume the offensive, and succeeded at first in defeating the French center under Massena, and in forcing their left into inextricable confusion, followed by total rout; but at the same time his own left was turned by Davoust, and this success followed up by a successful attack of Macdonald on their center, forced the Austrians to retreat, which they did in the most orderly manner, carrying with them 5,000 prisoners, and leaving 25,000 dead or wounded on the field of battle—the French loss being about equal. This drawn battle (the archduke having, as Savary says, "in reality no reason for retiring") had all the moral effects of a victory for the French; and was followed on July 11 by the armistice of Znaim, which resulted in the fourth treaty of Vienna.

WAGTAIL, *Motacilla*, a genus of birds of the family *motacillidæ*, which is now very generally regarded as a sub-family (*motacillinæ*) of *sylviadæ*, distinguished by a lengthened and slender bill, long and pointed wings, rather long and slightly curved claws, and a long narrow tail, which the bird incessantly wags up and down, with a jerking motion. The genus *motacilla* of Linnæus included many of the *sylviadæ* not belonging to this group, as the red-breast, nightingale, black-cap, and blue-bird. The genus *motacilla*, as now restricted, has a slender awl-shaped, straight bill; the nostrils oval, on the sides of the bill near the base, partly covered by a naked membrane; the wings of moderate size, the first quill-feather the longest, the second and third nearly as long as the first, the tertials very long; the tarsus much longer than the middle toe; the tail of twelve feathers, long, and nearly equal at the end.—The wagtails run with great celerity, and seek their food on the ground. Their food consists chiefly of insects and small seeds. They frequent the margins of rivers and lakes, inundated fields, and other moist

grounds. "While the cows are feeding in moist low pastures," says White (*Nat. His. of Selborne*), "broods of wagtails, white and gray, run round them, close up to their noses, and under their very bellies, availing themselves of the flies that settle on their legs, and probably finding worms and larvæ that are roused by the trampling of their feet." Wagtails make their nests on the ground, among moist herbage, or in stony places. Their flight is rapid and undulatory. They are natives of the temperate regions of the old world. No species is found in America.

WAHA'BIS, or WAHA'BITES, a recent Mohammedan sect, now dominant throughout the greater part of Arabia. The movement may be considered a puritanic reform, which seeks to purge away the innovations and corruptions introduced in the course of ages, and to bring back the doctrines and observances of Islam to the literal precepts of the Koran and of the Sunna (q.v.), or oral instructions of Mohammed himself. This purified faith the Wahabis consider it their duty to impose at the point of the sword—in this, too, following strictly the precepts and practice of Mohammed and the first caliphs. The founder of the sect, Ibn-abd-ul-Wahâb, was the son of an Arab sheik, or chief, and was born in Nejed or Nejd (the central highlands of Arabia), about the end of the 17th century. He is said to have visited various schools in the principal cities of the east, and to have lived some years in Damascus; and here he is represented as forming the resolution to restore in its primitive shape the ruined structure of Islam. Nor was the task an easy one. Throughout the Mohammedan world, the precepts of the Koran had fallen into abeyance, more especially among the Turks; and religion was little else than a round of external ceremonies—prayers, ablutions, fastings, the worshiping of the holy sheiks or saints at their tombs, and other superstitious innovations. In central and eastern Arabia where the faith of Mohammed had never taken deep root, matters were even worse. According to Palgrave, "almost every trace of Islam had long since vanished from Nejed, where the worship of the Djann (genii), under the spreading foliage of large trees, or in the cavernous recesses of Djebel Toweyk, along with the invocation of the dead and sacrifices at their tombs, was blended with remnants of old Sabæan superstition, not without positive traces of the doctrines of Moseylemah and Kermut. The Koran was unread, the five daily prayers forgotten, and no one cared where Mecca lay, east or west, north or south; tithes, ablutions, and pilgrimages were things unheard of." Central Arabia was at that time divided among a multitude of virtually independent chiefs. One of these chiefs, named Sa'u'd (or Saoo'd), a young man of ardent and capacious mind, who ruled over the small territory around the stronghold of Deraijeh, or Dureeyeh* (in Nejed), was the first important convert made by Ibn-abd-ul-Wahab after his return home; and the example of the prince was followed by his kindred and retinue. The Wahabi is said to have promised Sa'ud that if he would draw the sword in the cause of pure Islam, he would make him sole ruler of Nejed, and the first potentate in Arabia. The prophecy was fulfilled, partly in Sa'ud's reign, and fully in that of his son; and the Sa'ud dynasty is at this day the chief power in the peninsula, while the decendants of Ibn-abd-ul-Wahab (who lived till 1787) continue to act as spiritual directors, though without any acknowledged authority. It was about 1746 that Sa'ud began to act as apostle militant of the new, or rather revived Islam. One after another he subdued his heretical neighbors, offering them the alternative of conversion or extermination. Dying in 1765, he was succeeded by his son, Abd-ul-Aziz, who carried on the same policy with vigor and success. Extending his sway to Hasa (Al-Ahsa, as Col. Pelly spells it, and anciently Hajr), and other places on the Persian gulf, he was brought in hostile contact with the Turkish authorities of Bagdad, and from that place an expedition was sent in 1797 against the Wahabis by way of Hasa; but it failed to penetrate into Nejed, and proved fruitless. The Wahabis now grew bolder in their plundering excursions toward the Euphrates, and in 1801, Sa'ud, the son of Abd-ul-Aziz, led an army against the holy city of Meshed Hussein, or Kerbela, took it, massacred the greater part of the inhabitants, destroyed the tomb of Hussein, the grandson of Mohammed, and carried off the treasure. On this, a second Turkish army was sent from Bagdad against Nejed, but was routed, and the greater part slain. The conquest of Hejaz was next undertaken by the Wahabis. For two or three years, Ghaleb, the ruler of Mecca, had been more and more hemmed in by neighboring chiefs who had joined the Wahabis, and now, in 1803, Sa'ud collected a large army, and defeating Ghaleb in several battles, laid siege to Mecca, which, after a resistance of two or three months, surrendered at discretion. Not the slightest excess was committed, but the people had to become Wahabis—"that is, they were obliged to pray more punctually than usual, to lay aside and conceal their fine silk dresses, and to desist from smoking in public. Heaps of Persian pipes, collected from all the houses, were burned before Sa'ud's headquarters, and the sale of tobacco forbidden."—Burckhardt.

Failing to take Jiddah, into which Ghaleb had thrown himself, the Wahabi forces went northward, and, in 1804, took Medina, where they stripped the tomb of Mohammed of its accumulated treasures, and prohibited the approach to it of all but Wahabis, as they considered the reverence paid to it by the Turks and others as idolatrous. At

* Nothing is more perplexing than the orthography of Arabic proper names; every traveler spells them in a way of his own. In comparing Burckhardt, Palgrave, and col. Pelly, it is often difficult to identify the places and persons spoken about.

Medina, "the Wahabis enforced with great strictness the regular observance of prayers. The names of all the adult male inhabitants were called over in the mosque after morning, mid-day, and evening prayers, and those who did not obey the call were punished. A respectable woman, accused of having smoked the Persian pipe, was placed upon a jackass, with the pipe suspended from her neck, round which was twisted the long flexible tube or snake; in this state she was paraded through the town."—Burckhardt.

During these events, Abd-ul-Aziz had been assassinated, in the end of 1803, by a fanatical Persian, whose family had been murdered by the Wahabis at Meshed Hussein. He was succeeded by his son, Sa'ud II., who had for some time conducted the wars, and was perhaps the ablest ruler and warrior of the dynasty. For several years after the conquest of Hejaz, he continued to extend and consolidate his power. Plundering incursions were made to the very vicinity of Bagdad, Aleppo, and Damascus; while the Wahabi sheik of Asir (lying s. of Hejaz) imposed the new faith on a great part of Yemen. On the east, Sa'ud took the islands of Bahrein, annexed a part of the Persian coast on the e. side of the gulf, and exacted tribute from the sultan of Oman. This brought him into conflict with Great Britain, which sent (1808) a force, and severely chastised the Wahabi pirates that infested the commerce of the Persian gulf.

While these external struggles were going on, several of the southern provinces of Nejed broke out in revolt, instigated mainly, perhaps, by the local chiefs, whose power, formerly independent, was now circumscribed, or altogether taken away by the central government; but the rising was speedily suppressed, and a terrible example was made of the province of Harik and the town of Hutah, which last was completely demolished, and its inhabitants (the male inhabitants were reckoned at 10,000) butchered almost to a man.

From 1802, the Wahabis had prevented the great pilgrim caravans from reaching Mecca, both because they held the observances of the Turk and Persian hajjis to be idolatrous, and also because they were scandalized at the gross immorality and indecency which were openly practiced by these pilgrims. It may easily be conceived what horror spread through the Mohammedan world when it was told that the tomb of the prophet had been despoiled by heretics, who prevented the faithful from performing the most sacred duty of their religion. Accordingly, the sultan of Constantinople, the acknowledged protector of Mohammedanism, as early as 1804, imposed on Mehemet Ali, the newly appointed pasha of Egypt, the task of recovering the holy cities. With the dilatoriness, however, characteristic of the east, nothing was done till 1811, when an expedition was sent against them, under the command of the pasha's son, Túsún-bey. Medina was taken by the Egyptian forces in 1812, and Mecca in the following year; and a protracted and desultory warfare, with varying success, was kept up with the Wahabis in Hejaz and around its confines. At last, in 1815, Ibrahim pasha (q.v.) undertook to penetrate into central Arabia and crush the hornets in their nests. The enterprise was facilitated by the death of Sa'ud in 1814. He was succeeded by his son Abdallah, who, though an able warrior, was less adroit in securing unity of action among the numerous tribes under his sway. It was not, however, till 1818, and after repeated conflicts, that Ibrahim succeeded in decisively breaking the Wahabi force, and capturing their capital, Deraijeh, which was laid in ruins. Abdallah-ibn-Sa'ud was sent to Constantinople, where he and some of his ministers were beheaded (1818). Ibrahim continued some months in Arabia, consolidating his conquests throughout Nejed and the adjoining provinces. His policy was one of gentleness and conciliation toward the chiefs and common people, and of stern repression toward the fanatical religious teachers; and except among these, his name is said to be yet popular throughout central Arabia. But the folly and tyranny of the vice-governors whom he left, soon caused a general insurrection; the Egyptians had to retire to Kasim; and Turki, a son of Abdallah, was proclaimed sultan of Nejed, Riad being now chosen as the capital. Renewed expeditions were undertaken by the Egyptian commanders, driving, first, Turki from his capital for a time, and then his son and successor, Feysul; instead of whom, a chieftain favorable to Egyptian rule was appointed. But soon after the death of Mehemet Ali (1849), the Egyptians gave up the struggle; Feysul was recalled from exile; and under him and his son and vicegerent, Abdallah II., the Wahabi sway had become more powerful and extensive than ever. In 1870 Feysul was assassinated, and the dissensions between his two sons Abdallah and Sa'ud led to a civil war. This gave occasion to the Ottoman government to send a military force into the Persian gulf, which occupied Hofhuf, the capital of Hasa, but was unable to penetrate further into Nejed.

According to Burckhardt, there is not a single new precept in the Wahabi code. The only difference between the sect and the orthodox Turks (improperly so termed) is, "that the Wahabis rigidly follow the same laws which the others neglect, or have ceased altogether to observe. To describe, therefore, the Wahabi religion, would be to recapitulate the Mussulman faith; and to show in what points their sect differs from the Turks, would be to give a list of all the abuses of which the latter are guilty." One peculiarity of the Wahabis is their zeal against gaudy dress—silk and gold ornaments—and tobacco. In their wars of conversion, "No smoking" has been a kind of battle-cry. The recent traveler, Palgrave, who came into more intimate contact with the Wahabis than Burckhardt, has a much less favorable opinion both of their doctrines and their practice. He describes their empire as "a compact and well-organized government, where centraliza-

tion is fully understood, and effectually carried out, and whose mainsprings and connecting links are force and fanaticism. It is capable of frontier extension, and hence is dangerous to its neighbors, some of whom it is even now swallowing up. Incapable of true internal progress, hostile to commerce, unfavorable to arts and even to agriculture, and in the highest degree intolerant and aggressive, it can neither better itself nor benefit others; while the order and calm which it sometimes spreads over the lands of its conquest are described in the oft-cited *Ubi solitudinem faciunt, pacem appellant* of the Roman annalist. We may add, that its weakest point lies in family rivalries and feuds of succession, which, joined to the anti-Wahabian reaction existing far and wide throughout Arabia, may one day disintegrate and shatter the Nejedean empire, yet not destroy it altogether. But so long as Wahabiism shall prevail in the center and uplands of Arabia, small, indeed, are the hopes of civilization, advancement, and national prosperity for the Arab race." Col. Pelly characterizes the Wahabis as "Warlike Mohammedan Quakers."

The tenets of these puritans have taken root among the Mussulman population of India, and caused very considerable uneasiness. About 1826 Sejjid Ahmed became a convert to the Wahabite doctrines and preached them in the province of Oudh. Through the writings of his disciple Mohammed Ismail, the new faith drew many believers.

The following statistical table of the Wahabian empire was drawn up by Palgrave, mostly from the official registers at Riad:

Provinces.	Towns or Villages.	Population.	Military Muster.
1. Aared	15	110,000	6,000
2. Yemamah	32	140,000	4,500
3. Harik	16	45,000	3,000
4. Aflaj	12	14,000	1,200
5. Wadi Dowasir	50	100,000	4,000
6. Seley'yel	14	30,000	1,400
7. Woshem	20	80,000	4,000
8. Sedeyr	25	14,300	5,200
9. Kasim	60	300,000	11,000
10. Hasa	50	160,000	7,000
11. Katif	22	100,000	.....
Total	316	1,219,000	47,300

A more recent estimate places the total population of the empire at 1,133,000. A good many of the towns are large, and populous to a degree that the current notions of central Arabia would hardly lead us to look for. The following are among the most important of these towns: Eyun, Bereydah, Oneyzah, Toweym, Horeymelah, Mejmaá, Riad, the capital, Kharfah, and Hofhuf (Al-Hufhuf). Katif (Khutif) is the most direct port of the Wahabian dominions; and the province of Hasa in which it is situated is the richest.

To the n. of Nejed and its dependencies lies a kingdom formerly ruled over by a half-hearted ally of Feysul's Telal, the chief of Djebel Shomer, and consisting of five provinces — Djebel Shomer, Djowf, Kheybar, Upper Kasim, Teymar. This part of Arabia was overrun and converted during the first outbreak of Wahabi propagandism; but the conversion was only seeming, and during the interference of Egypt in Arabian matters the country regained a kind of independency. Since the death of Telal, Ottoman interference has been attempted. The great majority of the people are averse to Wahabiism. Still, the Wahabis have numerous partisans and missionaries and spies in all the towns, and their influence is hated and feared by prince and people. Even Oman, where the new Islam is said to be still more distasteful, has been brought in some degree under the political sway of the Wahabis, and pays a small yearly tribute.

Karsten Niebuhr (q.v.) is the first European writer who mentions the Wahabis; Burckhardt, *Notes on the Bedouins and Wahabis* (1830), gives a sketch of the Wahabi doctrines and of their history down to 1815; sir Harford Jones Brydges, for many years resident at Bagdad, to his *Account of the Transactions of His Majesty's Mission to the Court of Persia*, appends a "Brief History of the Wahauby;" Mengin, *Histoire de l'Egypt sous le Gouvernement de Mohammed Ali;* Corancez, *Histoire des Wahabis*, with maps. The most recent authorities on the subject are W. G. Palgrave's *Narrative of a Year's Journey through Central and Eastern Arabia*, 1862–63 (Macmillan & Co., 1865); and *A Visit to the Wahabee Capital*, by Lieut.Col. L. Pelly, H.M. political resident, Persian gulf, in *Geog. Soc. Journal*, 1865. See *Proceedings* of the Geog. Soc., 1880; *A Pilgrimage to Nejd*, 1881.

WAHKIAK'UM, a co. situated in s.w. Washington, having the Columbia river for its s. boundary; 244 sq.m.; pop. '90, 2526, chiefly of American birth. Co. seat, Cathlamet.

WAHOO. See ELM.

WAIB'LINGEN, a t. of Würtemberg, on the Rems, in the circle of the Neckar; pop. '90, 4786. It usually gets the credit of having given to the family of the Hohenstaufen

the title which became Italianized into Ghibellines (see GUELPHS AND GHIBELLINES) but Raumer (q.v.), the historian of the Hohenstaufen dynasty, upholds the claim of another Waiblingen in Würtemberg, on the Kocher, in the circle of Jaxt.

WAIFS, in English law, are goods stolen, and waived or abandoned by the felon on being pursued. The goods belong to the crown, but the owner, on doing diligence to prosecute and convict the thief, can have them again,

WAINSCOT (Sax. *wag*, a wall, and *scot* or *schot*, corresponding to Ger. *scheit*, a split or cut piece of timber—from *scheiden*, to divide; the word would thus mean wall-timber or boards), the name given to boards lining the interior walls of apartments. Such lining, usually in panels, is very common in Elizabethan architecture. The name is frequently applied to the best kinds of oak boards, from oak having been so much used for paneling.

WAINWRIGHT, JONATHAN MAYHEW, D.D., D.C.L., 1793–1854; b. England; of American parentage; came to this country, 1803, and graduated at Harvard college, 1812; became rector of Christ church, Hartford, Conn., 1816; assistant minister of Trinity church, New York, 1819; rector of Grace church, 1821; of Trinity church, Boston, 1834; took charge of St. John's chapel, Trinity parish, New York, 1837; visited Europe and the east, 1848–49, and Europe a second time, 1852, when he received from Oxford the degree of D.C.L.; elected provisional bishop of the diocese of New York, and consecrated in Oct., 1852. Among his published writings are: *There cannot be a Church without a Bishop* —a controversy with Rev. Dr. Potts, and *The Pathways and Abiding-Places of our Lord.*

WAIST, in a ship, is that portion of the upper deck lying between the fore and main masts. In it the larger boats are stowed, and along its gunwale the crew pile their hammocks during the day. In a steamer the waist is much broken into by the engine-room.

WAITE, HENRY RANDALL, PH.D., b. N. Y., 1845; graduated at Hamilton college, 1868; studied at Union theological seminary (Presbyterian), New York; resided in Europe, 1871–74, organizing American chapels at Rome and Geneva, and being chaplain at Rome; became editor of *Daily Evening Journal* at New Haven, 1874; associate editor of *International Review* at New York; lecturer on political science in the Syracuse university; and president of the political science association and of the national reform league, both of which were organized by his efforts. He has published *Sermons from the life of St. Paul at Rome,* and has written other works.

WAITE, MORRISON REMICK, LL.D., b. Lyme, Conn., 1816; graduated at Yale college, 1837, a classmate of William M. Evarts and Edwards Pierrepont; studied law at Lyme, and after his admission to the bar moved to Ohio, where he practiced successfully in Maumee City and Toledo. In 1849 he served in the state legislature, but after that, though frequently offered political and judicial positions, declined all nominations and built up a large practice in the higher branches of the law. In 1871 he was one of the counsel for the United States in the Geneva arbitration on the *Alabama* claims. He was president of the constitutional convention of Ohio, 1873, and in March of the next year was nominated as chief-justice of the United States by President Grant and confirmed by the senate. He d. 1888.

WAITS (anciently spelled *waightes*) is a name which has, at successive periods of our history, been given to different classes of musical watchmen. The word is one, in slightly varied forms, common in the sense of guard or watchman to all the Germanic languages. It is the German *wacht* or *wache*, Dutch *wagt*, Danish *vaght*, Swedish *wakt*, Scotch *wate*, and the English *watch*. How the word in the form of waits came to be exclusively applied to musical watchmen in England and Scotland, it is impossible to say. In the time of Edward IV. the waits appeared to have formed a distinct class from both the watch and the minstrels. It was their duty, we learn from Rymer's *Fœdera*, to pipe the watch nightly in the king's court from Michaelmas to Shrove Thursday four times, in the summer nights three times, and to make "the bon gayte" at every chamber door and office, for fear of pyckeres and pillers. The waits were not confined to the court; there were musical watchmen at an early period in many provincial towns. In Exeter a regular company existed in 1400. Beaumont and Fletcher (*Knight of the Burning Pestle*) speak of the "waits of Southwark as rare fellows as any in England." The word in the provinces was afterward sometimes applied to the town musicians, who may have represented the old waits, but who had no duties to perform as watchmen. The name was also given to the town band, or to private musicians when employed as serenaders. In this sense it is used in the *Tatler* (No. 222). The writer says that it had become so much the custom for lovers to employ the waits to help them through their courtship in Nottingham, that the ladies of that place could get no sleep by reason of riotous lovers who infested the streets with violins and bass-viols between 12 o'clock and 4 in the morning. Till recently the waits were officially recognized in London and Westminster. In London the post of leader of the waits was purchased; in Westminster the appointment was in the gift of the high constable and court of burgesses. In 1820 a Mr. Munro obtained the post of official leader of the waits for Westminster, with the exclusive right to serenade the inhabitants, and make application for Christmas-boxes. His prerogatives were invaded by other musicians, and he prosecuted several persons before the police courts. At present, in the metropolis, the waits are musicians who play during the night or early in the morning for two or three weeks before Christmas.

They call afterward at the houses of the inhabitants to ask for a Christmas-box. In Glasgow there were waits at an early period. The magistrates still grant a certificate to a few musicians, generally blind men, who play in the streets during the night and morning for about three weeks previous to New Year's day. Like the London waits, they call at the houses of the inhabitants, show their credentials, and ask a small subscription.—See Chambers's *Book of Days*, vol. ii. p. 742.

WAITZEN, a t. of Hungary, in the co. of Pest-Pilio-Soit, on the left bank of the Danube, 20 m. n. of Budapest, on the Vienna and Pesth railway. It is a bishop's see, and contains a noble cathedral with conspicuous dome. Pop. '90, 14,450.

WAIVER, in law, the neglect or refusal of a person to take advantage of his right. Every person must claim the exercise of his rights at the proper moment; his neglect or relinquishment will be regarded as a waiver. A party bringing suit against another may sometimes waive one remedy and pursue another.

WAKE (from the Anglo-Saxon *wacian*, to watch) is the English equivalent of the ecclesiastical vigil (q.v.). In early times, the day was considered as beginning and ending at sunset; Sundays and holidays, in consequence, began not on the morning, but on the previous evening (the *eve* of the holiday), and worshipers then repaired to the churches for worship. The following day was spent in amusement. Each church when consecrated was dedicated to a saint, and on the anniversary of that day was kept the parish wake. In many places, there was a second wake on the birthday of the saint. On these occasions, the floor of the church was strewed with rushes and flowers, and the altar and pulpit were decked with boughs and leaves. In the churchyard, tents were erected to supply cakes and ale for the use of the crowd on the morrow, which was kept as a holiday. The second part of the festival seems to have made most impression on the popular mind, and the word wake came to be applied to it. Crowds resorted to the wakes from neighboring parishes, hawkers or merchants were attracted by the crowds, and ultimately they became mere fairs or markets, little under the influence of the church, and disgraced by scenes of indulgence and riot. In 1285, Edward I. passed a statute which forbade fairs and markets to be held in country churchyards; but it does not appear to have put an end to the evil. In 1448 Henry VI. ordained that all showing of goods and merchandise, except necessary victuals, should be discontinued on the great festivals of the church. These regulations do not seem to have been strictly enforced. An act of convocation passed in 1536, during the reign of Henry VIII., seems to have effected a more important change. It ordered the day of the dedication of the church to be kept in all parishes on the first Sunday in October, and gradually that festival ceased to be observed. The saint's-day festivals were not, however, affected, and they are still kept in many English parishes under the name of "country wakes." A *lyke-wake* or liche-wake is a watching of a dead body (A.-S. *lic*) all night by the friends and neighbors of the deceased. The custom no doubt originated in superstitious fear either of passing the night alone with a dead body, or of its being interfered with by evil spirits. It must at all times have led to scenes ill suited to the occasion, and it now survives only among the lower classes in Ireland.—See Brand's *Popular Antiquities*.

WAKE, a co. in central North Carolina; 940 sq. m.; pop. '90, 49,207. It is the most populous county in the state. Co. seat, Raleigh; capital of the state.

WAKE, William, D.D., 1657–1737; b. England; graduated, Oxford, 1676; accompanied viscount Preston as chaplain to the English embassy to France; returning, was elected preacher to Gray's inn; had a long theological controversy with Bossuet; canon of Christ church, 1689; rector of St. James, Westminster, 1693; dean of Exeter, 1701; bishop of Lincoln, 1705; archbishop of Canterbury, 1716. He published a translation of *Apostolic Fathers;* three volumes of *Sermons*. He bequeathed his library and collection of coins, valued at £10,000, to Christ Church college, Oxford.

WAKEFIELD, a town in Middlesex co., Mass., on the Boston and Maine railroad; 10 miles n. of Boston. It was incorporated in 1868; contains several villages; and has the Beebe town library, public parks, armory, national, savings, and co-operative banks, electric light and street railroad plants, and manufactories of rattan goods, stoves, shoes, pianos, and ladies' underwear. Pop. '90, 6982.

WAKEFIELD, an important and handsome t. in the West Riding of Yorkshire, overlooking the Calder, 8 m. s. of Leeds, on the Lancashire and Yorkshire railway. The town consists of three principal and many minor streets, and among the chief buildings are the parish church, conspicuous from its lofty and elegant spire; the grammar-school (1591), a wealthy institution, attached to which there are exhibitions to the universities; the library and news-rooms, corn exchange, etc. Its benevolent and scientific institutions are numerous and important. The town has long been famous for its manufactures of woolen yarn and cloths. The district around Wakefield is agricultural, and the town is noted for its corn and cattle markets. Coal-mines are worked in the vicinity. Wakefield returns one member to the house of commons. Pop. '91, 33,146.

WAKEFIELD, Edward Gibbon, 1796–1862; b. England; became a land-surveyor. In 1826 he was imprisoned in Newgate on a conviction for forcibly abducting an heiress —with whom he went through a "Gretna Green" marriage, declared void by act of parliament. His three years' imprisonment furnished him material for a work on prison management. He subsequently resided in Australia, France, and New Zealand; intro-

duced the "Wakefield colonization system," somewhat resembling the pre-emption plan of the United States; took part in abolishing penal transportation; and wrote *A View of the Art of Colonization*, and other treatises on social and political questions. He died in New Zealand.

WAKEFIELD, ROBERT, 1480–1537; b. England; educated at Cambridge and on the continent; taught Greek, Hebrew, Chaldaic, and Syriac in France and Germany; prof. of Hebrew at the university of Louvain, 1519; returning to England became king's chaplain; advised Henry VIII. in regard to his divorce from Catharine of Aragon; lecturer in Greek at Cambridge, 1524; prof. of Hebrew at Oxford, 1530; canon of Wolsey's new college, 1532. He published various books, and was pronounced the greatest linguist of his time.

WAKE-ROBIN. See ARUM, TRILLIUM.

WAKULLA, a co. in n. Florida, having Apalachee bay and the gulf of Mexico on the s.e.; about 540 sq.m.; pop. '90, 3117. Co. seat, Crawfordville.

WALACHIA. See MOLDAVIA.

WALBRIDGE, HIRAM, 1821–70; b. Ithaca, N. Y.; graduate of Ohio university, 1841; studied law in Toledo, O.; admitted to the bar, 1843; brig.gen. of Ohio militia, 1844; engaged in business in New York in 1847. He was a democrat in politics; member of congress, 1853–55; opposed the civil war, declined a seat in President Lincoln's cabinet, but worked sedulously for the commercial interests of the country. He was on the Pacific railroad committee, 1869, and took a prominent part in the national commercial conventions at Chicago, Detroit, and Louisville.

WALCHEREN, an island in the Netherlands province of Zeeland, at the mouth of the Scheldt. The chief places are Middleburg, Flushing, and Vere or Campvere (q. v.). The surface is even, and a large part consists of rich arable land. Where it is not protected by natural downs, strong dikes have been formed, that at West Kappella being a magnificent work. The drainage water is carried off by large sea-sluices at Middleburg and Vere, and the island is crossed by a canal. Agriculture is the principal employment, and wheat, madder, and garden fruits are raised. Cattle rearing and the fisheries also give employment to many. The capital is Middleburg, and the chief port is Flushing. From the latter town, a railway has been constructed through w. and s. Beveland to Bergen-op-Zoom, joining the other continental lines. Flushing has a considerable shipping trade. The people are chiefly Protestants. In many parts are large artificial mounds, supposed to have been erected by the early inhabitants as places of refuge from high tides.

WALCHEREN EXPEDITION, one of the most disastrous military failures in the history of modern warfare, was undertaken, like that of sir John Moore to Spain, with the view of helping the continental allies of Britain, by creating such a diversion as would prevent the concentration of Napoleon's strength, in overwhelming amount, against any one of his opponents. The expedition was planned in 1807, when Prussia, Russia, and Austria were all in arms against France; but it was not till early in the summer of 1809 (when Napoleon, who had meantime overwhelmed Prussia, and reduced Russia to neutrality, was gradually forcing Austria to succumb) that the British ministry resolved to carry it out. The plan was to send a fleet and army up the Scheldt and attack Antwerp (the principal naval station and arsenal in the n. of France), whose fortifications, though formidable, were much in need of repair, and whose garrison at the time only numbered about 2,000 invalids and coast-guards; while there were not more than 10,000 French soldiers in Holland. The expedition, after numberless needless delays, at last sailed on July 28; and, to the number of 37 men-of-war, 23 frigates, 115 sloops and gunboats, accompanied by transports, carrying about 41,000 soldiers, reached the Dutch coast on the following day. But, instead of obeying the orders of the minister of war, lord Castlereagh, to *advance at once in force against Antwerp*, the commander-in-chief, lord Chatham (the elder brother of Pitt), frittered away his time in the reduction of Vlissingen (Flushing), which was not effected till Aug. 16, by which time the garrison of Antwerp had been re-enforced by king Louis Bonaparte with the troops at his command (about 6,000), and by detachments sent from France, which swelled the garrison, by Aug. 20, to 15,000 men. About the end of August, Chatham, who, as a general, was a methodical incapable, "found himself prepared" to march upon Antwerp, but by this time 30,000 men, under Bernadotte, were gathered to its defense, and the English army was decimated by marsh-fever, so that success was not to be hoped for. However, it was judged right to hold possession of Walcheren, in order to compel the French to keep a strong force on the watch in Belgium, and, accordingly, 15,000 men remained to garrison the island, the rest returning to England; but the malaria proved too fatal in its ravages, and as peace had been concluded between Austria and France, this force was also recalled. Thus an excellently devised scheme, through the utter stupidity of the agent chosen by royalty to carry it out, failed in every point of consequence, and ended in a loss of 7,000 men dead, and the permanent disablement of half the remainder. The failure of the Walcheren expedition

was made the occasion of furious onslaughts on the ministry in the house of commons and in the public journals.

WALDECK, a principality of Germany, consisting of the old co. of Waldeck, inclosed between Westphalia, Hesse-Cassel, and Prussia, and the small co. of Pyrmont, about 30 m. n. of Waldeck. The form of government was a constitutional and hereditary monarchy; but since 1868 the administration has been under the control of Prussia, and one member is sent to the Bundesrat and one to the Reichstag. The entire area was 433 sq. miles. Pop. '95, 57,766. The elevation of the country is greater than that of most districts of Northern Germany; and the scenery, continually alternating between mountain and valley, forest and plain, comprises scenes of much natural beauty. The two largest rivers are the Eder and Diemel, affluents of the Weser. Among the minerals found are gold, copper, iron, and lead; and mineral springs occur. Agriculture and cattle-breeding are by far the most common pursuits of the people, and with the exception of leather, no articles are manufactured to any extent. Capital, Arolsen.

WALDEN, John Morgan, d.d., b. in O., 1831; began his career as an itinerant preacher of the Meth. Epis. church in Ind.; was connected with the *Cincinnati Commercial*, and was prominent in the anti-slavery struggle in Kansas. He was supt. of public instruction for Kansas; preached in Cincinnati, 1860-68; was a secretary of the Freedman's Aid commission; and was elected bishop of the Meth. Epis. church, 1884.

WALDENSES (Valdenses, Valdesi, Valesi, Vaudois), are a Christian community who inhabit a mountain tract on the Italian side of the Cottian Alps, s.w. from Turin. The district is bounded on the n. by the Dora Ripaira, on the s. by the Po. It is inclosed on all sides by the spurs of the Alps, which divide it into three valleys—that of Perosa, drained by the Clusone; that of San Martino, drained by the Germanasca; and that of Lucerna, drained by the Pelice, all tributaries of the Po. These valleys lie between France and Italy, and immediately s. of the great western route into Italy by the passes of Mont Cenis and Genevre. The inhabitants are thus brought into communication with both countries; indeed, they speak a dialect more closely allied to those of Dauphiné than to those of Piedmont; and they have used French as well as Italian as the language of their liturgy. The religious doctrines of the Waldenses are now similar to those of the Reformed churches. There is a minister in each parish, called a *barbe*, and the synod is presided over by an elected *moderator*. The Waldenses had at one time bishops, but that was when the sect was more widely spread than it now is. Much has been said of the origin of the Waldenses. Their own historians assert that the community has remained from apostolic times independent of the church of Rome, and boast that they can show a regular apostolic succession of bishops from the earliest period of Christianity till that of the reformation. This statement has been very generally admitted by uncritical writers, but in the light of recent investigations, would seem to be no longer tenable. Dieckhoff (*Die Waldenser im Mittelalter*, Gött. 1851) and Herzog (*Die romanischen Waldenser*, Halle, 1853), have submitted the early history of the Waldenses to a critical examination; and the result to which they have come, after an examination of the manuscript records, is, that the Waldenses had not the early origin claimed for them, and were not Protestants before the reformation, although they entertained some opinions which, so far, were in anticipation of those held by the reformers. They are also of the opinion that the Waldenses do not take their name from *val, vallis*, a valley, as has been assumed, but from Peter Waldo of Lyon, a merchant of the 12th c., who was less the founder of a sect than the representative and leader of a wide-spread struggle against the pretensions of the clergy. The church would have tolerated Peter Waldo, as it had tolerated St. Francis of Assisi, the founder of the Franciscans, and perhaps have allowed him to form a new order, had he not trenched upon ground dangerous to the hierarchy. But he had the four gospels translated, and maintained that laymen had a right to read them to the people. He attacked most violently the whole body of the Church and the clergy, and brought down their wrath upon himself. His opinions were condemned by a general council in 1179, and he retired to the valleys of the Cottian Alps. A long series of persecutions followed, but Waldo's followers could not be forced to abandon their opinions. They continued to be known as the *Leonisti*, from the place of their origin—the poor people of Lyons, from their voluntary penury—*Sabotati*, from the wooden shoes they wore—and *Humilitati*, on account of their humility. It was natural that a body so severely shunned should stand aloof from the church, and even offer armed resistance; yet we have no evidence of the manner in which the Waldenses first became a separate community. They are now shown to have been identical with the followers of Waldo, but they must not be confounded with the Albigenses, who were persecuted at the same period. The protest of the Waldenses against the church of Rome only related to practical questions, that of the Albigenses related to matters of doctrine.

The Waldenses at first seem to have spread in the upper valleys of Dauphiné and Piedmont, to which Waldo retired. They were subjected to persecutions in 1332, 1400, and 1478, and driven into many parts of Europe, where their industry and integrity were universally remarked. So widely had the sect been scattered, that it was said a traveler from Antwerp to Rome could sleep every night at the house of one of the brethren. In Bohemia many of them had settled, and they, without forsaking their own community,

joined the Hussites, Taborites, and Bohemian brethren—a connection which led to a change in the principles of the Waldenses. They adopted the doctrines of the reformers, and this led to more serious persecutions than any they had previously undergone. Francis I. of France, in possession of Piedmont in 1541, ordered them to be extirpated. They were massacred at various places in Dauphiné and in the valleys they still occupy, more especially at Merindol and Cabrière. Several persons who refused to abandon their faith were burned alive, yet the sect continued to exist. In 1560 the duke of Savoy, who had recovered possession of Piedmont, urged by Pope Paul IV., forbade the Waldenses to exercise their faith, under the penalty of being sent to the galleys for life. The Waldenses sent him a petition and apology for their creed, which appeared to him so plausible, that he suggested that a conference should take place between the Waldensian and Romanist divines. He was, of course, told that the proposition was monstrous, and urged by the pope and the courts of Spain and France so effectually, that he dispatched 7000 men into the valleys, who were joined by two French regiments. The Waldenses offered a gallant resistance, but were overwhelmed by superior force. Many prisoners were burned alive, and women and children were at times slaughtered. The duke was displeased with these severities, and although denounced as no better than a heretic at Rome, granted the Waldenses an amnesty on condition that their service should only be performed at certain places in the valleys of Lucerna and San Martino. The Waldenses in the other districts, and especially the marquisate of Saluzzo, were then opposed by the Jesuits. Charles I. of England sent two embassies to the duke of Savoy to intercede in their behalf, but without avail. Victor Amadus I., not long after, ordered the Waldenses of Saluzzo, under the penalty of confiscation of property and death, to become Catholics; and the edict was so rigorously carried out that, in a few years, none of the sect remained in the district. Charles Emmanuel II., in 1655, directed a fresh crusade against these Waldenses. Some time before, the people of Lucerna, inflamed, it is said, by the discourses of Jean Leger, a popular preacher, set fire to a convent of Capuchins, and committed other excesses. An inquiry was made, and it was found that the Waldenses had purchased property and built churches and schools in districts where no concessions had been granted them. They were ordered within 20 days to sell their property, or profess Catholicism. They resisted, under leaders named Jayer and Janavel, but they could not oppose the forces sent against them. No quarter was shown to women and children, and severe measures were taken—more especially by the French and Irish mercenaries in the service of the duke—which, recorded by Jean Leger, were heard of with indignation in all Protestant countries. Subscriptions were made in England for those who had survived the massacre. The Swiss cantons, and the states of Holland, sent envoys to the duke. Cromwell addressed Latin letters to him, written by Milton, and also sent sir Samuel Morland, who collected numerous manuscripts connected with the history of the Waldenses, and brought them to England with him. A convention was concluded, by which the Waldenses were allowed again to exercise their worship. In 1685 Louis XIV. revoked the edict of Nantes, and ordered the duke of Savoy to compel the Waldenses to adopt Catholicism. They were accordingly commanded to emigrate or abjure their tenets within 15 days. They resisted, and were attacked by the troops of the duke on one side, and those of Louis XIV. on the other. They were overpowered, and the survivors could make no conditions. A large number were imprisoned at Turin, where many died; others were allowed to emigrate. Their whole property was confiscated, and handed over to Roman Catholic colonists. When the prince of Orange became king of England, the Waldenses who had settled in Switzerland resolved to return to their valleys under the guidance of Henry Arnaud, one of their pastors. In 1689 they gathered from all quarters to the rendezvous in the great forest of the Pays de Vaud. On the night of Aug. 16, they embarked on the lake of Geneva, landed on the opposite shore, and after encountering the most determined opposition, reached the valley of San Martino, after a perilous march of 31 days. During the winter a French army of 22,000 men entered their territories, and in the following summer attacked their fortifications, but were repulsed with great slaughter. Fortunately, the French and Piedmontese at this juncture quarreled, and the latter, to secure the services of the mountaineers, granted them an amnesty. They are said to have fought not less than 18 battles against the French, and to have lost only 30 men. This was the last persecution against the Vaudois; but it was not till 1848 that they were put on a level with their Catholic fellow-subjects. They had then 18 pastors and 15 congregations; in 1891 there were 17 mountain churches and 78 Sunday-schools; besides 43 congregations and 56 preaching stations in other parts of Italy, with 4428 communicants and 511 catechumens. The *Libera Chiesa*, a Protestant Italian church, is not connected with the church of the Valleys. The Waldenses have a college at Florence, and publish several denominational and missionary journals. See the works of Botta, Bender, Morland, Gelly, Muston.

WALDENSTRÖM, Paul, d.d., ll.d., a Swedish theologian and statesman, was born in 1838. He graduated at the University of Upsala in 1863, and entered the ministry; but in 1872 excited a controversy by advocating a moral theory of the atonement, and in 1877 he became the recognized leader of the Free Church movement. Since 1885 he has been a teacher in theology in the state school at Gefle, and also a member of the Swedish parliament. In 1889 he visited the United States, and was given the degree of

D.D. by Yale university. He has published, among many works, *The Lord is Holy; Reconciliation;* and a Commentary on the New Testament.

WALDO, a co. in s. Maine, having the Penobscot river on the e., the Penobscot and Belfast bays on the s.e.; 705 sq. m.; pop. '90, 27,759. It has a large export trade and important manufactures. Co. seat, Belfast.

WALDO, PETER. See WALDENSES.

WALDOBORO, a town in Lincoln co., Me.; on the Medomak river and the Maine Central railroad; 16 miles w. of Rockland. It was settled by German emigrants in 1748, and incorporated as the 32d town in Maine in 1773. It contains a public high school, circulating library, national bank, weekly newspaper, several shipyards, granite and marble works, lumber and saw mills, shoe and stave factories, canned goods, and carriages. Included in the town are several villages and a number of islands in the bay, the former comprising North Waldoboro, South Waldoboro, West Waldoboro, Orff's Corner, and Winslow's mills. The town is named after Gen. Waldo, who obtained a patent for the land from George II., and induced the German settlement. Pop. '90, 3505.

WALDSTEIN, CHARLES, A.M., L.H.D., PH.D., archæologist, was born in New York City, March 30, 1856. He studied at Columbia and at Heidelberg, receiving the degree of Ph.D. from the latter in 1875. In 1876 he studied both in Leipsic and in the British museum in London, and also delivered a course of art lectures in the museum. He spent 1878–79 in Italy and Greece. In 1880 he became lecturer in classical archæology at Cambridge, and in 1882 "Reader" in Greek art. In 1883 he delivered a course of lectures before the Royal Institute of Great Britain, and in 1886, a course at Columbia college. In 1888, while still holding his positions at Cambridge, he was appointed director of the American School of Archæology in Athens. In 1892 he was decorated with the order of the Saviour by the King of Greece. He has published *The Balance of Emotion and Intellect* (1878); *Essays on the Art of Pheidias* (1885); *The Work of John Ruskin* (1893), etc.

WALES, THE PRINCE OF. See ALBERT EDWARD, PRINCE OF WALES.

WALEWSKI, ALEXANDRE FLORIAN JOSEPH COLONNA, Count and Duke, 1810–68; b. Poland; reputed son of Napoleon I. by a Polish lady; educated at Geneva; fought in the Polish army; went to France after the fall of Warsaw, 1830; entered the army and was made capt.; relinquished military life and devoted himself to politics and literature; was sent to Egypt by M. Thiers on a diplomatic mission; received appointments under the Guizot ministry; was *chargé d'affaires* to Buenos Ayres at the outbreak of the revolution, 1848; was sent by Louis Napoleon ambassador to Florence, 1849; to London, 1854; minister of state, 1860–63; president of legislative assembly, 1865–67; was editor of the *Messager*, and published *Un mot sur la question d'Afrique; L'alliance Anglaise.*

WALHALLA (the hall of the fallen, i.e., heroes. See WALKYRIES), is, in northern mythology, the name of the place of residence for the fallen in battle. This brilliant hall stood in Gladsheim (the house of joy); in front of it was the beautiful grove Glasur, the trees of which bore golden leaves. Before the hall, which was so high that its summit could scarcely be seen, a wolf was hung, as a symbol of war, over which sat an eagle; the saloon itself, ornamented with shields, and wainscoted with spears, had 540 doors, through each of which 800 of the inmates (Einherjer) could walk abreast. For these Einherjer (i.e., the brave), who came after death to Odin, was it destined. Renowned chiefs, especially if they had desolated many countries, and wielded the blood-dripping sword far and wide, were met and welcomed by Bragi and Hermode as messengers from Odin. The hall was decorated to honor them; all the divine heroes stood up at their reception; the Walkyries tasted wine for them, which otherwise only Odin drank. All kings came to Walhalla, even when they did not die on the battle-field; in general, these joys seem to have been prepared only for those of high rank and the rich. As it was honorable to come to Walhalla with a great retinue, and to possess many treasures, the comrades of a leader who had fallen in battle killed themselves of their own free will, and in his grave were laid along with his horse and arms the treasures won in fight. Every morning the inmates marched out at the crowing of the cock, and fought furiously with another; but at midday all wounds healed, and the heroes assembled to the feast under Odin's presidency. Odin himself partook of nothing but wine; he gave the edibles to the wolves Geri and Freki, who sat beside him. The guests ate of the bacon of the boar Sahrimmer, and refreshed themselves with beer and mead, which flowed in abundance from the udder of the goat Heidrun; the attendant Walkyries handed them the drinking-horns, under Freyja's direction. Occasionally, the hero rode by night to his grave, where the beloved Walkyrie received him; he reposed in her embrace till, night disappearing, he exclaimed, "It is time to make the horse tread on the white stair of the sky; I must travel toward the west to the bridge of heaven before the cock awakes the warriors in Walhalla." The half of the fallen belonged to Freyja.

The name WALHALLA is also given to a magnificent structure erected by Ludwig I. of Bavaria (1830–41) as a temple of fame for all Germany. He conceived the project in 1806, when the fatherland was at its lowest point of degradation, and while he was yet crown-prince. The design of the building was by Klenze, and the chief sculptors of

Germany have contributed to the execution of the plan. It stands on an eminence 250 ft. above the Danube at Donaustauf, near Regensburg. The temple is of nearly the same dimensions and proportions as the Parthenon, and is built of marble. By means of statues, busts, reliefs, and tablets, the mythology and history of Germany are illustrated, and her greatest names commemorated. The undertaking cost 2,330,000 florins.

WALKE, HENRY, b. Virginia, 1808; entered the navy as midshipman, 1827. He took part in the capture of Tobasco, Vera Cruz, and Tuspan in the Mexican war, and ranked as commander at the beginning of the war of the rebellion. He held commands at the battles of Fort Henry, Fort Donelson, Island No. 10, Fort Pillow, the passage of the Vicksburg batteries, and other engagements; becoming a commodore in 1866, and rear-admiral in 1870; retired, 1871. He d. in 1896.

WALKER, a co. in n.w. Alabama, drained by the Black Warrior river and its affluents; 824 sq.m.; pop. '90, 16,078, includ. colored. Co. seat, Jasper.

WALKER, a co. in n.w. Georgia; about 404 sq.m.; pop. '90, 13,282, chiefly of American birth, inclu. colored. It contains Lookout Mountain and the famous battle-field of Missionary Ridge. Co. seat, Lafayette.

WALKER, a co. in e. Texas, drained by the Trinity and San Jacinto rivers; 740 sq.m.; pop. '90, 12,874, chiefly of American birth, inclu. colored. Co. seat, Huntsville.

WALKER, AMASA, LL.D., 1799–1875; b. Conn., was a merchant in Boston, 1825–40, and a prominent abolitionist; a delegate to the international peace conventions held in Europe, 1843 and 1849; a member of the Massachusetts legislature, 1848; a state senator, 1849; secretary of state, 1851–52; a member of the constitutional convention, 1853; and a member of congress, 1862–63; professor of political economy at Oberlin, 1842–49; and lecturer at Amherst, 1861–66. He published *Nature and Uses of Money and Mixed Currency; Science of Wealth;* a *Manual of Political Economy;* and, in connection with others, *Transactions of the Agricultural Societies of Massachusetts*, 7 vols.

WALKER, BENJAMIN, 1753–1818; received a business education; was a capt. in the 2d. N. Y. regiment; served as aid-de-camp to Steuben, and to Washington, 1781–82; secretary to the governor of New York after the revolutionary war; subsequently a broker in New York city. He was naval officer of New York under President Washington; member of congress, 1801–3. He was identified with the early settlement of Utica, N. Y., holding the position in 1797 of agent to the immense estates of the earl of Bute.

WALKER, FRANCIS AMASA, b. Boston, 1840; served in the war of the secession and was made brevet brig.gen., 1865; chief of bureau of statistics at Washington, 1869; superintendent of the census of 1870 and 1880; Indian commissioner, 1871; professor of political economy and history in the Sheffield scientific school of Yale college, 1873–81; chief of the bureau of awards of the Centennial exhibition, 1876; and after 1881, president of the Massachusetts institute of technology at Boston. Besides the census reports, he published *The Indian Question; The Wages Question; Statistical Atlas of the United States; International Bimetallism* (1896), etc. He d. in 1897.

WALKER, Rev. GEORGE, an Irish clergyman, distinguished for the part he took in the heroic defense of Londonderry against the army of James II., was born in the county of Tyrone, of English parents, in the early part of the 17th century. He was educated at the university of Glasgow, and, entering the church, became rector of Donoughmore. The early life of Walker was not remarkable. When the Irish army of James II. entered Ulster, and took possession of Kilmore and Coleraine, Walker sought refuge in Londonderry, the headquarters of "the Englishry" since the times of James I., when the confiscated lands of the county had been bestowed on the corporation of the city of London, and a Saxon colony, English and Scotch, had been planted there, who had converted a waste into the richest district of Ireland. The town was fortified sufficiently to protect it from the pike-armed Celtic peasantry, and it had resisted more than one attack. But it was not so defended as to oppose regular troops. Lundy, the governor, was in secret communication with the enemy, and prepared to hand over the town to them; but some of his own officers protested against this course, and the citizens, remarkable at the time for that high spirit which characterizes a dominant race, and the possession of those qualities which made the soldiers of Cromwell famous, determined not to yield. The bishop, Ezekiel Hopkins, in vain inculated the doctrine of passive obedience at a conference; he was interrupted by a lad, one of a daring band known as the "thirteen Scotch apprentices," who called out: "A good sermon, my lord—a very good sermon; but we have no time to hear it now." A Scotch fanatic named Hewson urged the Presbyterians not to ally themselves with the enemies of the covenant; but he was laughed at by his countrymen. The thirteen apprentices closed the city-gates, and defied the enemy. It was then that Walker, described as an aged clergyman who had taken refuge in the city, encouraged the townspeople to fight to the last. Walker saved Lundy from the rage of the populace, and enabled him to quit the city in safety. Maj. Baker, who soon after died, and Walker became joint-governors, aided by Capt. Adam Campbell. The siege is the most memorable in British history. It began in April, and lasted till the end of July, 1689. The inhabitants were reduced to the greatest extremities by hunger, but they were sustained to the last by the rousing

sermons preached to them by Walker in the cathedral, and the example he and Capt. Campbell set in heading sallying-parties. When the siege was raised by the English fleet entering the harbor, Walker went to London. He was warmly received at court, thanked by the house of commons, created D.D. by Oxford, and bishop of Derry by the king. Portraits of him were in every house in England, and his triumph would have been complete had the Presbyterians not thought that their share in the defense of the city was overlooked, and provoked useless controversy. Walker could not be induced to take quiet possession of his bishopric; he would head a troop at the battle of the Boyne, and he was there killed. A lofty pillar has been erected to his memory at Londonderry, and the Walker club and the Campbell club have kept alive to our times the recollection of the siege. Walker published in 1689 *A True Account of the Siege of Londonderry.*

WALKER, Gilbert Carlton, 1832–85; b. Binghamton, N. Y.; d. New York. He graduated at Hamilton coll.; interested early in politics; and was a successful lawyer in Chicago. Moving to Norfolk, Va., for his health, he became prominent in the business community as the founder of the Exchange national bank, the American fire insurance co., and the Atlantic iron works and dock co. As a candidate for membership of the Va. constitutional convention of 1867, he maintained strong ground against the party demanding test oaths and white disfranchisement; and although defeated in his canvass, he secured Pres. Grant's order to postpone the election which had been meant to sanction the views of his opponents. Soon afterwards, he became an independent candidate for the governorship of Va., the democrats withdrawing their nominee in his favor, thus securing his election by a large majority. He was elected, as a dem., to congress, 1874, serving two terms. His later life was spent at Binghamton and New York, in the practice of law.

WALKER, James, D.D., 1794–1874; b. Mass.; graduated at Harvard college in 1814, studied divinity, and was settled over the Unitarian church in Charlestown, 1818–39; when he became professor of moral and intellectual philosophy in Harvard college, of which he was president, 1853–60. Dr. Walker, who was editor of the *Christian Examiner*, 1831–39, published for undergraduate use editions of Reid *On the Intellectual Powers*, and Stewart's *Philosophy of the Active and Moral Powers; Sermons* (1861); *Memoir of D. Appleton White* (1863); and *Memoir of Josiah Quincy* (1867). He bequeathed to Harvard college his library and $15,000. He was a man of intellectual keenness and literary taste, with great moral fidelity and beauty of spirit.

WALKER, James Barr, D.D., b. Philadelphia, 1805; principal of an academy, New Durham, N. J.; studied law, Ravenna, Ohio, graduated at Western Reserve college, Hudson, Ohio, 1831; edited *Ohio Observer* at Hudson; *Watchman of the Valley*, Cincinnati; *Watchman of the Prairies;* studied theology; licensed as a Congregational preacher, 1841; established at Mansfield, Ohio, a private orphan asylum; preached at Sandusky; lecturer at Oberlin college and Chicago theological seminary on Harmony between Science and Revealed Religion. He published *Philosophy of the Plan of Salvation; God Revealed in Creation and in Christ; Philosophy of Skepticism; Philosophy of the Divine Operations in Human Redemption; Poems; The Living Question of the Age*, etc. He d. in 1887.

WALKER, James D., b. Logan co., Ky., 1830; removed to Ark., 1847; was admitted to the bar, 1850; fought as a col. in the confederate service, and after the war was solicitor-gen. of Arkansas. He was elected, as a dem., to the U. S. senate, 1878.

WALKER, John, 1732–1807; b. England; was a merchant, an actor, a school-master, and a teacher of elocution. In the last he attained great success in London, Oxford, Scotland, and Ireland. In 1772 he published *Pronouncing Dictionary of the English Language*, followed by *A Rhyming Dictionary; Elements of Elocution; The Critical Pronouncing Dictionary and Exposition of the English Language*, for many years the standard of the language; *Key to the Classical Pronunciation of Greek, Latin, and Scripture Proper Names; Outlines of Grammar.* He was educated a Presbyterian, but became a Roman Catholic.

WALKER, Robert James, 1801–69; b. Penn.; graduated at the university of Pennsylvania, 1819; studied law and was admitted to the bar, 1821. He began his political career at an early age. In 1826 he settled in Mississippi, became a prominent democratic leader, and was U. S. senator, 1837–45. He had great influence in destroying the U. S. bank, and in the admission of Texas to the union. From 1845 to 1849 he was secretary of the U. S. treasury. In 1857 he was made gov. of Kansas, but two years later resigned, "being unwilling to aid in forcing slavery on Kansas by fraud and forgery." He was loyal in the civil war, and as financial agent of the United States in Europe, effected large sales of U. S. bonds. He published the Mississippi Supreme Court Reports, 1818–32, *Arguments on the Mississippi Slave-Question*, 1841, and was for some time editor of a monthly magazine.

WALKER, Sears Cook, 1805–53; b. Mass.; graduated at Harvard college, 1824, taught school near Boston; removed to Philadelphia; taught and engaged in scientific labors; prepared, 1837, a plan for an observatory in connection with the high-school; contributed many observations to *American Journal of Science*, and the *Memoirs* of the *Philosophical Society;* published a memoir on the periodical meteors of August and November; was appointed to the Washington observatory, 1845; had charge of the longitude computations of the U. S. coast-survey, 1847; with Prof. Bache developed the method of determining difference of longitude by telegraph.

WALKER, Timothy, 1806–56; b. Mass.; graduated at Harvard college and the Harvard law school, and began the practice of law at Cincinnati in 1831. Two years later, in association with Judge Wright, he founded a law school in which he was professor till 1844. He became presiding judge of the Hamilton co. court of common pleas in 1842. He afterward edited the *Western Law Journal.* He wrote an *Introduction to the Study of American Law,* and other works.

WALKER, William, 1824–60; b. Tenn.; studied medicine and law; edited the *Crescent* newspaper, New Orleans; co-editor of *San Francisco Herald,* 1850; started in San Francisco, 1853, an expedition for the conquest of Sonora; landed at La Paz, Lower California; proclaimed the independence of the peninsula; declared himself president; captured two or three towns, annexed Sonora to his territory; received a re-enforcement under Col. Watkins, and with 100 men set out overland for Sonora; their provisions being exhausted, the party dissolved, Walker surrendered to the U. S. authorities at San Diego, was tried, and acquitted. He landed in 1855 with 62 men in Nicaragua, gained two battles, took possession of Granada, and was appointed generalissimo of the republic; afterward caused himself to be elected president. A powerful insurrection was excited by his arbitrary acts, and after several battles he surrendered, May 1, 1857, with 16 of his officers, to Com. C. H. Davis of the U. S. sloop-of-war *Mary,* and was taken to the United States. Again he set out, landing at Punta Arenas, Nicaragua, Nov. 11; was obliged by Com. Paulding, U. S. navy, to surrender with 132 of his followers, and taken as a prisoner to New York. June 16, 1860, he left New Orleans, landed at Truxillo, was captured, condemned by a court-martial, and shot.

WALKER, William David, d.d., b. New York, 1839; graduated at Columbia coll., 1859, and at the General theol. sem., 1862; ordained priest in the Prot. Epis. church, 1863. He had charge of Calvary chapel, New York; was consecrated missionary bishop of Northern Dakota, 1883, and as bishop of Western New York, 1896.

WALKER, William Johnson, 1790–1865; b. Charlestown, Mass.; son of Maj. Timothy Walker; graduate of Harvard university, 1810; studied medicine, practiced in Charlestown, and became distinguished as a surgeon. In 1861 he established professorships in mathematics at Williams and Tufts colleges, and built Walker chapel at Amherst; the worth of the property given being estimated at $90,000. The total amount of his gifts was $400,000, and at his death in Newport, R. I., he divided $1,000,000 in bequests for educational purposes.

WALKING-LEAF. See Leaf-insect.

WALKING-STICK, the popular name of many insects of the family *phasmidæ* (q.v.), destitute of wings, and having a long, slender, cylindrical body, like a small stick with the bark on, the delicate legs resembling little twigs. Their habits are very similar to those of the leaf-insects or walking-leaves, and their peculiar appearance is, in like manner, their protection. Most of them are natives of warm climates, and they are widely distributed. Some of them attain a large size. *Phasma gigas,* an East Indian species, is 7 or 8 in. long. A species, between 3 and 4 in. long, *P. femoratum,* is found even in the northern and north-western parts of the United States.

WALKY'RIES, beings of the Scandinavian mythology (q.v.), the legend of whom is the most terribly beautiful in the whole system. The name is derived from the old Norse *val,* which signifies a heap of slaughtered men, and *kjora,* to choose. *Val* itself contains the notion of chosen, elect, being allied to Ger. *wahlen,* Scotch *wale,* to choose. The walkyries, also called battle-maidens, shield-maidens, wish-maidens, are charming young women who, adorned with golden ornaments, ride through the air in brilliant armor, order battles, and distribute the death-lots according to Odin's commands. Fertilizing dew drops on the ground from the manes of their horses, light streams from the points of their lances, and a flickering brightness announces their arrival in the battle. With their charming glance, they rejoice the glazing eye of the hero, and lead him to Walhalla, where they act as his cup-bearers. Two walkyries, Hrist and Mist, are cup-bearers to Odin himself.

They differ in regard to their origin; some of them spring from elves and other superhuman beings; some also are the daughters of princes, who in their lifetime are numbered among the walkyries, showing all their qualities, and when they die, their spirits become walkyries. They ride generally in companies of three, or of three times three, or four times three, and have the gift of changing themselves into swans. They often choose noble heroes for lovers. Whoever deprives a walkyrie of her swan-robe gets her into his power. But the song of the walkyries sounds terrible, as sitting on a hill, they weave the fateful battle-web. The walkyries were frequently confounded with the norns or destinies. They were also conceived under the figure of the clouds. Thus, Hrist signifies dark sky, and Mist signifies quaking. Most of the names of the walkyries, however, relate to war and battle.

WALLABOUT BAY, in Brooklyn, in the East river, opposite the s.e. extremity of Manhattan island. The small island which divides it from the East river, and the land bordering on the bay form the Brooklyn navy-yard. During the revolutionary war the British prison-ship *Jersey* was stationed in Wallabout bay.

WALLACE, a co. in w. Kansas, having the state line of Colorado for its w. boundary; about 900 sq. m.; pop. '90, 2468, chiefly of American birth, with colored. Its surface consists of fertile prairies, part of the great plains, and is destitute of timber. It was organized in 1875. Co. seat, Sharon Springs.

WALLACE, Alfred Russel, traveler and naturalist, was b. in Monmouth, England, Jan. 8, 1822, and was educated for the profession of land-surveyor and architect, a calling he exercised until 1845, when he devoted himself exclusively to naturalistic studies and researches. He spent four years on the Amazon, and eight years amongst the Malay islands, making extensive zoological collections. It was while living in the east that, unaware of Mr. Darwin's cognate researches and speculations, Wallace formed and committed to writing a theory of development by natural selection, though not using the latter term. Valuable contributions to zoology, botany, and cognate subjects are to be found in his *Travels on the Amazon and Rio Negro* (1853); *Palm Trees of the Amazon* (1853); *The Malay Archipelago* (2d ed. 1869); *Contributions to the Theory of Natural Selection* (1870). *The Geographical Distribution of Animals* (1876) practically founded a new science. *Tropical Nature* appeared in 1878. In a work *On Miracles and Modern Spiritualism* he vindicates views that have found few champions among men of science. He published *Australasia* (1879); *Island Life* (1880); *Land Nationalization* (1882); *Australia and New Zealand* (1893), etc.

WALLACE, Horace Binney, 1817–52; b. Penn.; educated at the university of Pennsylvania and the Princeton college, where he graduated, 1835; studied medicine and law, but never practiced. He assisted Judge Hare in editing *American Leading Cases; Smith's Leading Cases;* and *White and Tudor's Leading Cases in Equity;* published a novel, *Stanley, or the Recollections of a Man of the World,* and left works on European travel and literary criticism, published posthumously. In 1852 he was attacked by brain disease and committed suicide. His brother, John William, b. Penn., 1815, also studied law; 1842–53; was reporter for the U. S. circuit court (3d circuit), and in 1864 was appointed reporter of the U. S. supreme court, which position he held till his death, 1884. He edited various collections of noted law cases.

WALLACE, Lewis, b. Ind., 1827; served through the Mexican war, and afterward practiced law in his native state, and was a state senator for four years. He was adj.-gen. of Indiana at the beginning of the war of 1861–65; was soon made brig.-gen. of volunteers, and commanded a division at fort Donelson, receiving a maj.-gen's commission for his gallantry. In 1863 he prevented the capture of Cincinnati by Gen. Kirby Smith. Taking command of the 8th army corps, he met Early marching on Washington, and was defeated by him at Monocacy in July, 1864. Gen. Ord was directed by Gen. Halleck to supersede Wallace, but the latter was promptly reinstated by Grant. Wallace had, in fact, succeeded in his object, which was to give Grant time to re-inforce Washington from City Point. He was afterward a member of the court which tried the assassins of Lincoln, and president of the court which tried Wirz of Andersonville. He was governor of New Mexico in 1878–80, and minister to Turkey, 1881–85. He published *The Fair God* (1873); *Ben-Hur* (1880); *The Boyhood of Christ* (1889); *The Prince of India* (1893), etc. His wife is known as a brilliant and picturesque writer of historical and descriptive sketches.

WALLACE, Robert, d.d., b. Scotland, 1831; educated at Geddes institution, the high school, Edinburgh, and the universities of St. Andrews and Edinburgh, graduating m.a. in the former, 1853; ordained in the Presbyterian church, and became successively minister of Newton-upon-Ayr, 1857; of Trinity college church, Edinburgh, 1860; of Old Greyfriars, Edinburgh, 1868; received degree of d.d. from the university of Glasgow, 1869; elected professor of church history in the university of Edinburgh, 1872; succeeded Dr. Russel as editor of the *Scotsman,* 1876.

WALLACE, William, the famous Scottish patriot, was the younger son of a knight of good family in the s.w. of Scotland. Neither the date nor the place of his birth has been ascertained; but there is no doubt that the former may be assigned to the middle of the reign of Alexander III. Nothing certain is known of his education or his early years. Blind Harry's half-fabulous poem has indeed inseparably associated his birth with Ellerslie, his boyhood with Dundee, and his youthful manhood with Ayrshire; but his true history, even in the next generation, was so obscure, that it is now impossible to separate truth from falsehood or exaggeration. He first appears in the light of authentic history as the chief of a band of insurgents against Edward, king of England. Taking advantage of his superior power, of his influence over the barons of Norman race, who then were the foremost persons among the nobility of Scotland, and of the position of umpire to which he had been chosen by the various claimants to the Scottish crown, Edward had established his supremacy over the northern kingdom, and afterward deposed John Baliol, and attempted to govern in his own absolute right. See Scotland, *History.* The injustice of the claim, and the cruelty with which it was enforced, roused the opposition of all classes in Scotland except the higher nobles. The gentry and the middle and lower classes of the Lowlands, had for many years identified themselves with the country in which they dwelt, rather than with the great English race from which most of them drew their descent; and what has been called the war of independence began, which resulted in the deliverance of Scotland from foreign rule, at the cost of the

comparative civilization and tranquillity which the country had enjoyed under the descendants of Malcolm Canmore. In this struggle Wallace was the most successful leader; and in the course of the year 1297 the insurrection became general. Edward himself was at that time in Flanders; but his general in Scotland, the earl of Surrey, led his army to Stirling. On Sept. 11 they encountered the Scots under Wallace, and were completely defeated. The whole kingdom submitted to Wallace; who, passing the border, ravaged Cumberland and Northumberland without opposition. On his return from this expedition he was elected by his countrymen governor of Scotland, in name of king John, whose title was still recognized. In the following year Edward in person entered Scotland at the head of a numerous army. He was met at Falkirk (q.v.) by Wallace on July 22; but the Scots were defeated. It is generally assumed that the jealousy of some Scottish nobles, who envied the position of the governor, had aided in bringing about the disaster, and Wallace, in consequence resigned his high office. With this event, his brilliant public career may be said to have terminated. All that is certainly known is that he continued to struggle for his country's independence, and never made his submission to Edward, or took those oaths of fealty to him which were so lightly made by the Scottish nobles, and as recklessly broken. The events of this period related by modern writers under the name of "Lives of Wallace," are either transactions in which there is no evidence that he took any part, or the doubtful legends which, as years went on, gathered round the name of the Scottish hero. Some documents of undoubted authenticity make it probable that he was for some time in France. The close of his life forms an exception to this obscurity. When Edward offered pardon to the other Scottish leaders on certain terms, Wallace was excepted by name. If he chose to surrender, he might do so, but it was to be without conditions, and his life was to be at the king's mercy. Efforts were also made to discover his retreat and secure his person, and these were finally successful. In the year 1305 he was seized by some of his own countrymen, and delivered to Edward. He was carried to London, and with a mockery of the forms of justice, tried for treason. He denied the charge, asserting, with truth, that he had never been the vassal or subject of Edward; but his plea was disregarded. He was condemned and executed on Aug. 23; and his death was accompanied by acts of barbarity uncommon even in that age, and marking the merciless character which distinguished the later years of the English king. Contradictory as are the accounts of the English and Scottish chroniclers, it is not difficult to discover the true character of Wallace. He was the true leader of a national insurrection against a foreign yoke. The cruelties inflicted in his invasion of England are undeniable, but he did what he could to mitigate them; and he should not be severely blamed if, under far greater provocation, he tolerated what the good king David, in his war of the standard, was unable to prevent. His memory lives, and will ever live in the hearts of his countrymen, who know that they owe to him and to those who followed in the same course, that their history has not been as unhappy as the history of Ireland. The chief authority for the life of Wallace, as told by popular Scotch writers, is the poem of Henry the minstrel, who lived, however, nearly two centuries after his hero, and whose narrative is an almost unbroken series of picturesque impossibilities. The fullest modern account is that given by Mr. Tytler in the first volume of his *History of Scotland,* and in his Life of Wallace in the first volume of his *Scottish Worthies:* but Tytler is to a large extent *Blind Harry* over again, with judicious excisions.

WALLACE, William A., b. Huntingdon co., Penn., 1827; received an academic education and was admitted to the bar, 1847; was a state senator, 1862–75, and speaker of the senate in 1871; chairman of the democratic state committee for five years; member of the commission to suggest amendments to the state constitution, 1874; U. S. senator, 1875–81; and again elected to the state senate, 1882. He d. in 1896.

WALLACE, William Vincent, a British musician and composer of operas, was born at Waterford of Scotch parents, June 1, 1814. He early attained proficiency as a performer on the pianoforte and violin—his performances on the latter instrument bringing him under the notice of Paganini. After being for some years leader of the orchestra of a Dublin theater, he emigrated to Australia, where he lived for a considerable time in the bush, and then suddenly appeared in Sydney as a musician, and gave concerts in Australia, New Zealand, India, and America. In 1845 he came to England, and wrote his first opera, *Maritana,* which was an immediate success both in London and Vienna, and still holds the stage as one of the most popular of English operas. *Matilda of Hungary* followed in 1847. During a sojourn of some years in Germany, Wallace added further to his musical culture; and after again visiting America, composed *Lurline,* which was brought out in London in 1860, with even greater success than *Maritana.* In 1861 he produced *The Amber Witch;* in 1862, *Love's Triumph;* and in 1863, *The Desert Flower.* Wallace died at the château de Bagen, in the s. of France, Oct. 12, 1865, leaving another opera, *Estrella,* nearly completed. Without possessing genius of the very first order, Wallace was a highly-cultivated musician; the freshness of the motives, and the brilliancy of the orchestration of his operas, particularly *Maritana* and *Lurline,* have stamped their author as one of the chief English composers of this century.

WALLACH'IA. See Moldavia.

WALLACK, James William, 1795–1864; b. London; played at Drury Lane theater with Edmund Kean in Shakespearean parts. He came to New York in 1818, making his appearance at the Park theater as Macbeth the same year. He assumed the management of Drury Lane theater in 1820; opened the National theater, New York, in 1837; and Wallack's lyceum, afterward called Wallack's theater, at the corner of Broome street and Broadway, in 1852; it was rebuilt at Broadway and 13th street in 1861, and afterwards rebuilt at Broadway and 30th street. He was an excellent comedian.

WALLACK, John Lester, b. New York, 1820; son of James William. He was the proprietor of Wallack's theatre (see Wallack, James William), and was long known as one of the most finished actors on the American stage. He d. 1888.

WALLA WALLA, a co. in s.e. Washington. In 1875 the new county of Columbia was formed from its e. portion; 1296 sq.m.; pop. 1890, 12,224. Co. seat, Walla Walla.

WALLA WALLA, city and co. seat of Walla Walla co., Wash.; on Mill creek and the Washington and Columbia river and the Oregon Railroad and Navigation Co.'s railroads; 245 miles e. by n. of Portland, Or. It was incorporated as a town in 1859 and as a city in 1862; is the seat of Whitman college (Cong.), the U. S. military post of Fort Walla Walla, a U .S. penitentiary, and the state penitentiary; and contains Roman Catholic and co. hospitals, Paine high school, Baker public school, Park school, St. Vincent's academy for girls, St. Patrick's school for boys, street railroads, gas and electric light plants, gravity system of waterworks supplied from springs, national and private banks, and daily and weekly newspapers. Pop. '90, 4709.

WALLENSTEIN (or, more correctly, **WALDSTEIN**), Albert Wenceslas Eusebius von, Duke of Friedland, Sagan, and Mecklenburg, the most remarkable of the long series of eminent men who owe their prominence on history's page to the thirty years' war, was the third son of a noble though not wealthy Bohemian family, and was born at the château of Hermancè, in Bohemia, Sept. 15, 1583. His parents, who were Protestants, intrusted the care of his education to the Moravian brotherhood of Koschumberg, who, however, made little of their stubborn and passionate pupil. On his parents' death, his uncle, Albert Slavata, a zealous Catholic, took charge of the wayward youth, and having won him over to his own creed, sent him to the Jesuit *convictorium* at Olmütz, and to the universities of Altorf, Bologna, and Padua, where his education, such as it was, was completed. Wallenstein's course of training had not eradicated, or even moderated, the prominent faults in his natural disposition; on the contrary, his wilfulness and independent spirit had gathered stability and strength from ineffective opposition; and his first prominent appearance on the stage of events showed a man of extreme individuality, gifted with great and versatile ability, but equally remarkable for obstinacy, passion, and pride. He afterward visited Germany, France, and Holland, took service in the imperial army, then engaged with the Turks in Hungary, and, returning home at the close of the war (1606), married an aged widow of noble rank, who, at her death (1614), left him the whole of her great wealth. This, along with the fourteen domains bequeathed to him by his uncle, made him one of the richest and most influential lords of Bohemia, a position recognized by the imperial court by the bestowal on him of the title of count and the military grade of col. A second marriage in 1617 with the daughter of count Harrach, the emperor's favorite, and Wallenstein's firm adherence to the imperial side during the Bohemian insurrection; his maintenance, at his own expense, of a large body of troops; and his brilliant and well-directed gallantry at the battle of Prague, and in various contests with Mansfeld and Bethlem Gabor, added a powerful influence at court to his hitherto only local eminence. The latter, however, was now much increased by his purchase, at much less than their value, of sixty confiscated lordships in Bohemia; and Ferdinand II. felt himself impelled to recompense the valuable services of his faithful subject by (1623) raising him to the dignity of a prince of the empire, with the title of *duke of Friedland.* (Friedland is a town situated close to the Prussian frontier, about 60 m. n.n.e. of Prague.) Two years after, when the impossibility of maintaining an army sufficient to restrain the Protestant league from uniting with the Danes against him, threw the emperor almost into despair. Wallenstein, seizing such a favorable opportunity of gratifying his ambition, offered to raise, equip, and maintain 50,000 men free of charge, provided he were intrusted with the absolute command, and allowed to appoint his own officers: a proposal greedily accepted by the emperor. Wallenstein raised 30,000 in Bohemia; adventurers from all quarters flocked to his standard; and in a short time his army far exceeded the promised number. With this motley but not ill-disciplined array, he then marched into North Germany, and acting in concert with Tilly (q.v.), routed Mansfeld at Dessau, hunted him through Silesia and Moravia, and on his junction with the army of Bethlem Gabor in Hungary, compelled, by skillful strategy, the combined forces to remain on the defensive. Released by a truce with the Transylvanian prince and the death of Mansfeld, he returned by Silesia, recovered the fortresses which Thurn had captured, forced the elector of Brandenburg to submit to the emperor, and joined Tilly in annihilating the military power of Denmark. The value of these services to the emperor's cause was inestimable, as Ferdinand well knew, and he accordingly turned a deaf ear to the loud complaints of the

North Germans, who had suffered grievously from the rapacity, oppression, and license which Wallenstein's soldiers were allowed to exercise without the slightest opposition; and rewarded their leader by the gift of the Mecklenburg duchies, the rank of general issimo on land, and admiral of the Baltic. Wallenstein speedily made himself master of his new territory; fitted out a fleet of 15 sail, by the aid of which he captured Usedom and Rugen, with various Baltic ports, and laid siege to Stralsund. But the Danes annihilated his navy; and the Swedes succoured Stralsund, the siege of which he abandoned in despair. But as under cover of the dread inspired by Wallenstein's arms, Ferdinand had resumed his tyrannical and aggressive schemes (see THIRTY YEARS' WAR) in Germany, the Catholic league, headed by the duke of Bavaria, became bitter adversaries of Wallenstin, and backed by the intrigues of France (which was represented at Vienna by father Joseph, a master of subtle and unscrupulous diplomacy), partly forced and partly cajoled the emperor to dismiss Wallenstein, an act for the probable consequences of which even Ferdinand, with his extraordinary fortitude, trembled. Wallenstein, however, disappointed his sovereign's fears and his enemies' hopes by obeying with apparent cheerfulness, being somewhat moved thereto by the predictions of his favorite astrologer,* who declared his star to be only temporarily eclipsed and that it would soon shine forth again with far greater luster; and retired to Prague, where he lived in his magnificent palace in sovereign state, surrounded by a court composed of barons, knights, and the principal officers of his army. But the insult and injury he had received were eating into his soul; the frankness and affability to his subordinates, which had hitherto distinguished him, were changed for a gloomy taciturnity; and much of his time was spent in solitude, brooding over his wrongs, and scheming for revenge on the duke of Bavaria, whom he justly accused of being the cause of his disgrace; though all the while he kept a calm but eager watch over the changes of opinion in the court of Vienna, where several of the ministers and numerous secret agents were either in his pay, or devoted to his interests. His eminent services, his immense popularity, and his great talents, pointed him out as the only hope of the empire after Tilly's death, and Ferdinand saw himself forced almost to kneel to his haughty subject, and beseech him again to gird on his sword; but Wallenstein for a long time affected the utmost indifference to re-engaging in active service, and at last consented only on such conditions as made him the independent ruler of the empire in military affairs. With the Swedes on the Danube, the Saxons in Bohemia, and the army of the League almost annihilated, the emperor had no choice; and Wallenstein, three months afterward, was at the head of 40,000 men, well armed and disciplined. But commands and entreaties were in vain employed to induce him to save Bavaria from the Swedes; and he lay idle at Leitmeritz, gloating over the pangs of his enemy, till, on Austria being threatened, he advanced to Eger, and by menacing at once Saxony and Nuremberg, brought Gustavus to a stand-still. The two armies lay opposite each other for 10 weeks, each suffering the extremities of famine, hardship, and sickness, in the hope of wearying out the other. At last, when half their numbers had succumbed, Gustavus, who had made a fruitless attempt to storm Wallenstein's camp, retreated to the Danube, whence his skillful opponent soon drew him by marching on Saxony. The two again confronted each other at Lutzen (q.v.), and though Wallenstein was completely defeated, it was chiefly owing to the superior discipline and *morale* of his opponents. His army was recruited and reorganized in Bohemia; and, unable to make head against Saxons and Swedes combined, he found it advisable to gain time by amusing his antagonists with illusory negotiations, after repeated vain endeavors to persuade the emperor to come to terms with the Protestant princes. Meantime his old enemies of the league were in full activity at Vienna; and the emperor, chagrined at the humiliations to which he had subjected himself to gain Wallenstein's aid, was not slow to give credit, real or feigned, to their misrepresentations; his ill-concealed dislike was developed into hatred by the stubborn pertinacity with which Wallenstein insisted on the full observance of the terms of their agreement; and on Wallenstein, who was kept well informed of the state of matters at court, attempting to attach his officers permanently to himself by obtaining their signatures (Jan. 12) to an agreement to that effect, the emperor (Jan. 24, 1634) declared him a rebel, and ordered two of his old officers, Piccolomini and Gallas, who had for some time been acting as spies on his actions, to take him dead or alive. Wallenstein, with some devoted adherents, including a guard of 200 dragoons, took refuge in Eger, but was there assassinated, Feb. 25, 1634. Wallenstein was tall, thin, and wiry, with lively brilliant eyes, tawny-reddish hair, and an unhealthy-looking, yellow complexion. "He was far superior to his sovereign in true policy, liberality of sentiment, and religious toleration; but these qualities only rendered him more obnoxious to the bigoted emperor and his ministers. As a general, he holds the foremost rank, vigilance and presence of mind, great judgment and unflinching perseverance, being his prominent characteristics; and of him alone can it be said that he checked the progress and foiled the designs of the great hero of Sweden. After his death, it was seen that the treacherous murder of one who had twice saved the empire from destruction called for some justification; and accord-

* Wallenstein, during his attendance at the Italian universities, had deeply studied astrology; and although far too much has been made of this fact by his biographers, there is no doubt that the mystic doctrines of this pseudo-science had a strong hold on his mind, and at times much influenced his conduct.

ingly a paper was published by imperial authority, in which an attempt was made, by misrepresenting every overture he had made to his opponents, and every scheme he had employed to divide his numerous enemies at court, to prove that he had constantly meditated treason from the time of his first disgrace. This view and its opposite have found numerous and enthusiastic supporters; but without going further into detail, we may observe that the overtures made by him to the Swedes and Saxons while in command were undoubtedly *ruses de guerre*, and were invariably found to be such by his opponents; that when the Saxons invaded Bohemia, and took Prague, where he was residing in disgrace at the time, he took no part on either side, except such measures as an influential citizen would adopt for the safety of the inhabitants from insult and spoliation; and lastly, that when, after he had been declared a rebel, he *did* make "treasonable" overtures to Bernhard of Weimer, the latter, though Wallenstein's defection would at that time have been of the utmost importance, could not convince himself that this was not another artifice; a proof that the former overtures were as above stated.—See Coxe's *House of Austria;* Harte's *History of the Life of Gustavus Adolphus* (1759); Pelzel's *Geschichte der Böhmen* (Prague, 1774, 1779, and 1782); *Wallenstein's Briefe* (ed. by Forster, 1826); Ranke's *Geschichte Wallenstein's* (1869); Gindely, *Neues über Wallenstein.*

WALLER, a co. in s.e. Texas, bounded on the w. by the Brazos river; 500 sq.m.; pop. '90, 10,888. Co. seat, Hempstead.

WALLER, Edmund, celebrated as one of the refiners of English poetry, was b. at Coleshill, Herts, March 3, 1605 or 1606. He was of an ancient and opulent family, and having passed through Eton and King's college, Cambridge, was returned to parliament, at the early age of 18, as member for Amersham, Bucks. In 1631 he married a London heiress, who died shortly afterward; and the rich widower made suit to lady Dorothy Sidney, eldest daughter of the earl of Leicester, whom he poetically and perseveringly commemorated under the name of Saccharissa. Lady Dorothy, however, was inexorable: "she was not to be subdued," as Johnson says, "by the powers of verse." Meeting him in her old age, she asked the poet when he would again write verses upon her, and he ungallantly replied: "When you are as young, madam, and as handsome as you were then." In the long parliament, Waller joined the party of Hampden (who was his cousin), and he was one of the commissioners appointed to negotiate with king Charles I. at Oxford in 1642. He was soon gained over by the royalists, and entered into a conspiracy against the dominant party in the house of commons, for which he was fined £10,000, and banished the kingdom. His conduct on this occasion was mean and disgraceful. He not only confessed all he knew, but all that he suspected; attempted to criminate innocent persons, and humbled himself before the house of commons in language inexpressibly abject and humiliating. After eight years' exile, spent in France and Italy, he was suffered to return to England; and he then became a supporter of the commonwealth, and a panegyrist of Cromwell, to whom he was distantly related. When Charles II. was restored, Waller was equally ready with a poetical congratulation; but his loyal strains were much inferior to those with which he had hailed the protector; and it is said that when Charles reminded him of this fact, the poet wittily replied: "Poets, sir, succeed better in fiction than in truth." Up to his 80th year, Waller continued a member of the house of commons, delighting all parties by his wit and vivacity. He died at Beaconsfield, Oct. 21, 1687. Waller began early to write verses, and published two collections of his poems—one in 1645, and another in 1664. An edition appeared in 1711, edited by Atterbury; and one in 1729, with copious "Observations" by Fenton. Pope has eulogized the *sweetness* of Waller's verse.

WALLER, Edwin, b. Va., 1800; removed to Texas, where he was made alcalde. The *Sabine*, a vessel belonging to him, carrying cotton on which the Mexican government had laid a duty, evaded its payment; Waller was imprisoned. On his release he brought back 2 cannons, which were of use in the war that ensued, and in which Waller was active. He helped to frame the constitution of Texas, was the first mayor of Austin, and chief justice of Austin county. He selected Austin as the site for the capital.

WALLER, Thomas M. (Armstrong), b. New York, abt. 1840. He began life as an orphan newsboy in New York; drifted to Conn., where he was adopted by the late Robert K. Waller, of New London, whose surname he assumed. He attended the New London high school, studied law, and gained a high reputation in his profession; was a member of the state legislature for several terms; secretary of state, 1870; mayor of New London for six years; state attorney, 1876–83; democratic governor of Connecticut, 1882–85; and U. S. consul-general at London, 1885–89.

WALLETTE, a former co. in w. N. Dakota, having the Missouri river for its s. boundary; now included in Williams co.

WALLFLOWER, *Cheiranthus*, a genus of plants of the natural order *cruciferæ*, having the siliques quadrangular from the prominence of the nerves on the back of the valves, the seeds in a single row in each cell, the stigma deeply 2-lobed, the lobes bent back. The flowers are in racemes. The species are annual, biennial, or perennial herbaceous plants, some of them almost shrubs. The Common W. (*C. cheiri*) is found in rocky places and on old walls in the s. of Europe, and also, but less abundantly, in the middle of Europe and in Britain. In its wild state, its flowers are always yellow; but

in cultivation they exhibit a considerable diversity of colors, chiefly brown, purple, and variegated; and they attain a larger size. It is a universal favorite, on account of the delicious odor of its flowers. The varieties in cultivation are very numerous; but there are among them no marked distinctions. Double and semi-double flowers are not uncommon. The plant is perennial, but in gardens is generally treated as a biennial, although fine kinds are propagated by cuttings, which soon strike root under a hand-glass.

WALLING, George Washington, b. N. J., 1823, studied law, but in 1842 the death of his father changed his plans and he became a steamboat engineer. He served in that position on a revenue cutter during the Mexican war, and at its close became a police officer in New York city. In 1853 he was promoted to the grade of captain, and in 1866, inspector, in which capacity he greatly strengthened the efficiency of the force. In 1874 he became superintendent of the force, and in 1885 was retired on a pension. He d. in 1891.

WALLINGFORD, a town and borough in New Haven co., Conn.; on the Quinepiac river and the New York, New Haven, and Hartford railroad; borough 12 miles n. of New Haven. Besides the borough, the town contains the villages of East Wallingford, Yalesville, and Tracy. There are three high schools, nearly a dozen district schools, public and Simpson libraries, Rosemary hall (P. E.), the State Masonic home, national and savings banks, electric street railroad, a trotting park, and manufactories of silver-plated and light brass goods, rubber goods, wheels, etc. Pop. '90, town, 6584; borough, 4230.

WALLINGFORD, a small, but ancient and interesting, municipal borough of England, in the county of Berks, and on the right bank of the Thames, 13 m. n.n.w. of Reading. Pop. '91, 2989.

WALLIS, Rev. John, d.d., a very eminent English mathematician, was the eldest son of the Rev. John Wallis. incumbent of Ashford in Kent, and was born there, Nov. 23, 1616. He was brought up with a view to the church, and was educated for his profession, to the strict exclusion of all other branches of knowledge, in accordance with the prevailing practice of the time, which was in his case carried to such an extent that even ordinary arithmetic was wholly neglected. Wallis never saw a book of arithmetic till he was 15 years old, and then only by accident. At the age of 16, he was entered at Emmanuel college, Cambridge, where at that time mathematics found no place in the course of study, being esteemed merely mechanical. After a brilliant career, he took his degree, was chosen a fellow of queen's, and took orders in 1640. On the outbreak of the civil war, he sided with the parliament, and was of great use to his party in deciphering intercepted correspondence, an art in which like Vieta (q.v.) and Battista la Porta, he was eminent. In 1644, he was one of the secretaries of the assembly of divines at Westminster, holding at that time the living of St. Gabriel, Fenchurch street; and, in the following year, he joined with other eminent men in the establishment of the meetings for mutual instruction, which, 17 years afterward, developed into the royal society. It was not till 1647 that he commenced the study of mathematics; and, in 1648, he was chosen Savilian professor of geometry at Oxford. The rapid progress he had made in his mathematical studies was evidenced by the publication of his greatest work, the *Arithmetica Infinitorum*, with a treatise on conic sections prefixed, in 1655. In the same year commenced his well-known controversy with Hobbes—regarding a quadrature of the circle, which the latter believed he had effected—which was continued at intervals till 1663, and was marked by the usual quaint caustic satire of the time. Wallis had, of course, the right side of the dispute; but unfortunately for posterity, his manly feeling of forbearance toward a deceased antagonist (Hobbes died in 1679) prevented him from admitting his polemical treatises into the collection of his works, which was published 1693–99. Numerous other mathematical works, as the *Mathesis Universalis* (1657), *Commercium Epistolicum* (1658), *Cuno-Cuneus* (1663), *De Proportionibus* (1663), *De Æstu Maris* (1668), a treatise on mechanics (1669, 1670, 1671), editions of the works of Horrocks (1673), of the arenarius and quadrature of Archimedes (1676), and of Ptolemy's harmonics (1680), a treatise on algebra (1685), an edition of Aristarchus and of Pappus (1688), etc., were the products of his originality and industry. We have besides numerous minor theological works, polemical and expository, from his pen, none of which, however, are important enough to call for mention. Of his other works, the treatise on logic (1687) is of the highest excellence, and even at the present day is well worthy of perusal; and his English grammar (1653), written in Latin for the use of foreigners, has only of recent years, when the true principles of grammar are becoming better understood, received the attention it merits. About 1658, Wallis joined the party who were in favor of a restoration of kingly government, and his talent for deciphering was now put in practice against his former friends, an act for which he has been abused with virulent injustice. At the restoration he was confirmed in his professorship, was appointed keeper of the archives at Oxford, and royal chaplain. In 1692, he was consulted as to the adoption of the Gregorian calendar, and his strong disapproval decided the government to retain the old style. He died Oct. 28, 1703.

It is exclusively as a mathematician that Wallis's name has obtained permanently a niche in the temple of fame; though as an expositor of the cardinal doctrines of Christianity he was fully on a par with South and Sherlock; but his eminence in the former

character has thrown into shade even his services as a scholar, and few at the present time remember that it was he who first edited the musical works of Ptolemy, Porphyrius, Aristarchus of Samos, and the later work of Briennius, though the manner in which these labors were effected indicates unquestionably an immense expenditure of labor, and a high degree of scholarship. His *Arithmetica Infinitorum* is a successful attempt to solve, by means of the summation of series to infinity, a number of the more simple problems of the calculus, such as the evaluation of all cases of $\int x^m dx$; and, in extension, to discover the limit of $\int (a^2 - x^2)^n dx$, of which the quadrature of the circle is a particular case. There are numerous other results, which are, at the present time, considered to belong to the more advanced stages of the calculus; and, in fact, Wallis is another example of the strange blindness which, in full possession of a principle, neglects to suit it with a generalized form of expression. The best known of Wallis's results is his formula for π, which gives

$$\frac{\pi}{4} = \frac{2.4.4.6.6.8....}{3.3.5.5.7.7....} \text{ ad infinitum.}$$

WALLIS, Severn Teackle, b. Md., 1816; graduated at St. Mary's college, Baltimore, 1832; studied law and was admitted to the bar, 1837. Since 1870 he has been provost of the Maryland university, and is a trustee of the Peabody institute of Baltimore. He has published *Glimpses of Spain* (1849); and, *Spain, her Institutions, Politics and Public Men* (1853).

WALLON, Henri Alexandre, b. France, 1812; educated at the Paris normal school. In 1840 he was appointed professor at the Sorbonne, and gave lectures on geography and history. In 1871 he was elected to the national assembly as a moderate conservative. In 1875 he became minister of public instruction in the Buffet administration. He proposed the clause by which the republic was constitutionally established. In 1876 he was elected to the senate. Among his works are *La vie de Jésus et son nouvel historien* (1864), answering Renan; *La Terreur* (1872); and *Les Représentants du Peuple en l'An II.* (1888–90).

WALLOONS, the name given to a population belonging to the great Romanic family, more especially to the French stock, and occupying the tract along the frontiers of the German-speaking territory in the South Netherlands, from Dunkirk to Malmedy. They are located more particularly in the Ardennes, in parts of the departments of Pas-de-Calais, Nord, Aisne, and Ardennes in France, but chiefly in South Brabant, as well as in the provinces of Hainault, Namur, Liége in Belgium, and in the greater part of Luxemburg, and finally in some towns and villages in the neighborhood of Malmedy in Rhenish Prussia. The Walloons, whose numbers in Belgium, where they are principally established, are stated at 2 millions, are the descendants of the old Gallic Belgæ, who held their ground among the Ardennes mountains when the rest of Gaul was overrun by the German conquerors, but became eventually Romanized, especially in their language, which appears now as a patois or popular dialect of French; of all the French dialects, however, the greatest number of Gallic words have been preserved in it. See the unfinished work by Grandgagnage, *Dictionnaire Etymologique de la Langue Wallone* (Liége, 1845). The name Walloon, in Dutch, *Walen*, sufficiently shows their Gallo-Romanic origin, and their relationship, partly by race and partly by language, with the Galli, Gaels, Walese, Welsh, Walachians, etc. The Walloons of the present day resemble their French more than they do their German neighbors. They are squat and middle-sized, with powerful limbs, dark hair, deep sunk, fiery, dark-brown or blue eyes. They surpass their Flemish neighbors in adroitness, activity, and skill; and their French in earnestness, perseverance, and diligence. In impulsiveness, they resemble the latter more than the former, but their anger sooner cools than that of the more deeply feeling Fleming. It is worthy of notice that the Belgian revolution was pre-eminently the work of the Walloon districts, and the most eminent statesmen of modern Belgium are of Walloon descent. It was against the Walloon spirit and tendencies that the Flemish movement (see Flemish Language and Literature) was chiefly directed.

WALL-PAPER. See Paper-Hangings.

WALL-PIECE, a small cannon (or, in ancient times, an arquebus) mounted on a swivel, on the wall of a fortress, for the purpose of being fired at short-range on assailants in the ditch or on the covert-way. There are distinct evidences that the great wall of China was originally constructed for the reception of wall-pieces.

WALL-PLATE, a piece of wood laid along the top of the wall of a building to receive the feet of the rafters of the roof (q.v.).

WALLSEND, a t. in the co. of Northumberland, England, 4 m. e.n.e. from Newcastle, celebrated for its collieries. Pop. 91, 11,620.

WALL-TREES, in horticulture, are fruit-trees trained on walls for better exposure of the fruit to sunshine, and for the heat radiated from the wall. Brick walls are generally preferred, and have a great advantage in the regularity with which the nailing can be

accomplished, but trees are often also trained on stone walls, and the walls of houses are sometimes used for this purpose. Trees are trained on walls in hot-houses as well as in the open air. Flued walls are often used, the fruit being thus partially forced by artificial heat; and screens of various kinds, as of reeds, canvas, and oiled paper, are sometimes employed to protect blossoms in spring. Woollen nets are also much used for this purpose, and a net even with wide meshes affords much protection from spring frosts. Wall-trees, intended permanently to occupy the wall, are generally trained in the nursery with a dwarf stem only 5 or 6 in. in length, so that the branches may cover the whole wall, and no available part of it may be lost. It is usual, however, in planting to introduce *riders* alternately with the permanent wall-trees, which are grafted or budded on tall stocks, and occupy part of the wall till the other trees have become large enough to require it all for themselves. Garden-walls are generally 12 or 14 ft. in height. Different modes of training wall-trees are practiced, of which the principal are known as *fan training* and *horizontal training*. In the former, the branches are arranged like the spokes of a fan; in the latter, a main stem is led up, from which they are spread out horizontally on both sides. Different modes are preferred for different kinds of trees, and the art of the gardener is dispayed in keeping to his plan of training, and *laying in* branches so as completely to fill up the space, and make every part of the wall productive. There is a Dutch mode of training, which consists in leading two chief branches horizontally to right and left, and training shoots from them straight up to the top of the wall. It is seldom employed in America, except for white currants. Riders are not unfrequently trained in a star-like form, some branches being led downward, in order to fill the wall as quickly as possible. It is necessary for the gardener in training wall-trees, to consider the habit of each kind, particularly whether fruit is chiefly to be expected on young branches or on the *spurs* of older branches. Superfluous branches must in all cases be carefully removed, and among these are to be reckoned all *fore-right shoots*, or branches which project straight from the wall. The use of small strands of cloth along with nails, to fasten branches to walls, is familiar to every one. These strands are renewed from year to year, so that they may not cause disease by interfering with the growth of the branches.

WALNUT, *Juglans*, a genus of beautiful trees of the natural order *juglandaceæ*. This order is nearly allied to *amentaceæ* (q.v.), and particularly to the sub-order *cupuliferæ* (q.v.) or *corylaceæ*, but differs in having the ovary one-celled, with a solitary erect ovule. The flowers are unisexual, the male flowers in catkins, the female in terminal clusters. The species, of which not quite thirty are known, are mostly natives of North America; a few are found in Asia. All are trees with alternate pinnated leaves. The genus *juglans* is distinguished by monœcious flowers, with 18 to 24 stamens; and a drupe with a deciduous fleshy husk, which bursts irregularly, and a deeply wrinkled shell (*putamen*) of two valves, within which is the seed, curiously lobed and wrinkled, with a membranaceous *testa* and partial dissepiments. The species of hickory (q.v.) were formerly included in this genus.—The Common Walnut (*J. regia*) is a native of Persia and the Himalaya, but has long been cultivated in all parts of the s. of Europe. The date of its introduction is unknown, but it was certainly cultivated by the Romans in the reign of Tiberius. It is a lofty tree of 60 to 90 ft., with large spreading branches. Its foliage resembles that of the ash. The leaves have 2 to 4 pair of leaflets and a terminal one. They have a fine balsamic odor when bruised; this quality, however, being much more marked in some trees than in others. An infusion of them has been found useful in scrofula; and when bruised and rubbed on the skin they are efficacious in curing itch. Placed in wardrobes, they prevent the ravages of moths. The sap is limpid like water, but contains much sugar, so that the tree is sometimes tapped for it like the sugar-maple, and the sugar is procured by evaporation. A pleasant kind of wine is also made from it. An excellent pickle and a kind of ketchup are made of the unripe fruit. The ripe fruit is one of the best of nuts, and is an important article of export from many parts of the s. of Europe. Walnuts are also exported in large quantities from Cashmere and other Himalayan regions to supply the markets of India. The outer husk is removed before the nuts are brought to market. In the s. of Europe walnuts are a very considerable article of food, and when perfectly fresh they are wholesome and nutritious, although in the state in which they are imported into Britain they are not easily digestible. Just before they are ripe they are much used in France with vinegar, salt, pepper, and shallots. Among the varieties of walnut in cultivation is one with a very thin shell, which is much esteemed. Walnuts yield by expression a bland fixed oil, which under the names of *walnut oil* and *nut oil*, is much used by painters, and in the countries in which it is produced is a common article of food. The *cake* left after the expression of the oil is sometimes used as an article of food, and is also used for feeding cattle and poultry. The timber of the walnut is of great value, and is much used by cabinet-makers. Gun-stocks are made of it. It is light, although hard and fine-grained. The wood of young trees is white and little esteemed; that of old trees is brown, veined and shaded with darker brown and black. The wood of the roots is beautifully veined. Both the root and the husks of the walnut yield a dye, which is used for staining light-colored woods brown. The walnut, when meant to become a timber-tree, is best sown where it is to remain, as the roots are much injured by transplanting. The best kinds of

walnut for fruit are generally grafted. The walnut succeeds well in Britain as an ornamental tree, even in the n. of Scotland, although it seldom quite ripens its fruit except in the warmest parts of England. It was probably brought to England by the Romans. It takes its name from being foreign (A.-S. *wealh* or *walh*).—Very similar to the common walnut is the BLACK WALNUT (*J. nigra*) of North America, found in most parts of the United States except the most northern. It is a very large and beautiful tree, the trunk sometimes 6 or 7 ft. in diameter. The leaves have more numerous leaflets than those of the common walnut. The timber is even more valuable than that of the common walnut, and is used for the same purposes. The fruit, however, is very inferior, although it is sold in the markets of American cities. The partial dissepiments of the kernel are thick and woody.—The BUTTER NUT (*J. cinerea*) is abundant in the northern and northwestern states of North America, and in Canada. It is a tree only about 50 ft. high, with trunk about a foot in diameter; leaves with 15 to 17 leaflets; the fruit elongated, and externally covered with a viscid substance. The nut is hard and rough, with prominent ridges, of good quality, and sometimes brought to market in America. The wood is not apt to split or warp, and is useful for many purposes. Sugar is obtained from the sap, as from that of the maple, but is of inferior quality. The inner bark is a mild cathartic resembling rhubarb in its properties. The leaves reduced to powder are used for blistering, like cantharides.—To the natural order *juglandaceæ* belongs the genus *engelhardtia*, found in the Malayan archipelago and the Himalaya. The wood of *E. Roxburghiana*, a Himalayan species, is much valued by turners.

WALPOLE, HORACE, third son of sir Robert Walpole, fourth earl of Orford, was born in 1717. He was educated at Eton and Cambridge. After finishing his education, he traveled abroad for some years, principally in Italy, where he seems to have acquired those tastes for which he afterward became so well known. In 1741 he returned to England, and took his seat in parliament. But he had no taste for politics, and never took any active part in public life. In 1747 he purchased a piece of ground near Twickenham. Here he built his famous mansion—Strawberry Hill. Its erection and decoration may almost be said to have formed the principal occupation of his long life. In 1758 he published his *Catalogue of Royal and Noble Authors*. This was followed by *The Castle of Otranto; The Mysterious Mother;* and the *Historic Doubts on the Life and Reign of Richard III.* The works, however, to which he owes the preservation of his name are his *Letters*. These will always be interesting as pictures and records of the society and fashionable gossip of his day. Their interest is, however, considerably marred by their palpable want of truthfulness. On the death of his nephew in 1791 he became fourth earl of Orford. He died in his 80th year on March 2, 1797. "The faults of Horace Walpole's head and heart," says Macaulay, "are indeed sufficiently glaring. His writings, it is true, rank as high among the delicacies of intellectual epicures as the Strasburg pie among the dishes described in *Almanach des Gourmands*. But as the *pâté de foie gras* owes its excellence to the diseases of the wretched animal which furnishes it, and would be good for nothing if it were not made of livers preternaturally swollen, so none but an unhealthy and disorganized mind could have produced such literary luxuries as the works of Walpole. . . . . The conformation of his mind was such that whatever was little seemed to him great, and whatever was great seemed to him little. Serious business was a trifle to him, and trifles were his serious business."—See *Letters*, edited by Cunningham (8 vols., 1857); Macaulay's Essay on *Letters of Horace Walpole;* Seeley's *Horace W. and his World*, 1883. ; Dobson, *Horace Walpole* (1890).

WALPOLE, Sir ROBERT, third son of Robert Walpole, M.P., by Mary, daughter of sir Jeffrey Burwell, was born Aug. 26, 1676, at Houghton, in Norfolk. He received his education at Eton and at King's college, Cambridge. On July 30, 1700, he married Catharine, daughter of sir John Shorter, lord mayor of London. On Nov. 28 following, he succeeded to the family estates on the death of his father. In 1702 he was elected member of parliament for King's Lynn; and in 1705 he was nominated one of the council to prince George of Denmark. In this latter capacity he appears to have won the esteem of Godolphin, Marlborough, and other whig leaders. In 1707 he was appointed secretary at war; and in 1709 treasurer of the navy. Shortly after this, however, his fortunes suffered a temporary eclipse. He was found guilty by the house of commons of "a high breach of trust and notorious corruption," and accordingly, on Jan. 17, 1712, he was expelled the house, and sent to the tower. There can be little doubt that he had all his life a profound faith in bribery, and never scrupled to exercise it; but his punishment on this occasion seems rather to have been the result of party animosity than of virtuous indignation on the part of the house. He had all along been a strong Hanoverian, and on the accession of George I. he was restored to fortune. He was made a privy councilor, and had various other high offices conferred upon him. On the impeachment of Bolingbroke and others by his means, he became, in 1715, chancellor of the exchequer, and first lord of the treasury. A disunion of the cabinet having arisen in 1717, he resigned office, bringing in a sinking-fund bill on the day of his resignation. In opposition, he was the determined enemy of the South sea scheme. He was recalled to office on the retirement of the earl of Sunderland in 1721; and from this time to his final retirement in 1742, the life of Walpole may be said to be the history of England. In 1723 his son was created baron Walpole

In 1737 his power was a good deal shaken by the disputes which had arisen between the king and the prince of Wales; the latter siding with the opposition, which began to grow very formidable in the questions which arose about this time between England and Spain. Walpole was opposed to war; the grand principle of his action being, according to archdeacon Coxe, "the love of peace;" according to Macaulay, however, his aim was not the peace of his country, but of his own administration. In 1740 a motion was made in the house to petition the king to remove sir Robert Walpole "from his majesty's presence and counsels forever." This motion was negatived by a large majority; but the power of the great minister was evidently shaken. He resigned on Feb. 2, 1742, when he was created earl of Orford, with a pension of £4,000 a year. Charges of bribery were now brought against him, and a committee of investigation was ultimately appointed by the house of commons. It consisted of 21 members, of whom only two were of his own party. The report was against him, but it was unsupported by evidence, and proceedings were ultimately dropped. The rest of Walpole's life was spent in tranquillity and retirement. He died in 1745, aged 68. In private life he was amiable and good-tempered. Love of power appears to have been his ruling motive of action. He had strong common sense, with clearness of political vision, and next to his own interest he had at heart the interest of his country. Doubtless he bribed largely, but as Macaulay says: "We might as well accuse the poor Lowland farmers who paid black-mail to Rob Roy, of corrupting the virtue of the Highlanders, as accuse sir Robert Walpole of corrupting the virtue of parliament."—See Coxe, *Memoir of Life and Administration of Sir Robert Walpole*

WALPUR'GA, or **WALPURGIS,** SAINT (otherwise *Walburga*), followed her brothers St. Wilibald and St. Wunnibald (sons of a king of the West Saxons), in the time of St. Boniface, from her native country, England, to Germany, to help them in extending Christianity. Wilibald established the bishopric of Eichstadt about 741; and Wunnibald, the neighboring convent of Heidenheim about 745, the direction of which last Walpurga undertook, after his death (about 763), as the first abbess, and continued till the end of her own life (778). Her bones, from which, according to the oldest biography, a miraculous healing oil flowed, were transferred to Eichstadt, where a convent was erected in her honor. That old biography was written toward the end of the 9th c. by a monk, Wolfhart, in the monastery of Hasenried, and contained, like all the later legends, which are based solely upon it, only a multitude of marvelous stories of the usual stamp. A somewhat more special significance lies in the trait that Walpurga was not molested by biting dogs, and was in consequence invoked for protection against them and other ferocious animals. The veneration of Walpurga became wide-spread. Throughout all Germany, and even in France, the Netherlands, and England, churches and chapels were dedicated to her, relics of her were shown, and festivals celebrated in her honor. The feast of Walpurga falls properly on Feb. 25; but as in some German calendars it is assigned to May 1, the name of Walpurga has become associated, in a quite accidental way, with some of the most noted popular superstitions. May 1 had been one of the most sacred days of all paganism; it was the time of a great sacrificial festival, and of the old May assembly of the people. For centuries on May 1, informal courts of justice continued to be held, the joyful May procession took place, and the kindling of the sacred May-fire. See BELTEIN. When afterward the old heathen gods had been completely degraded into devils by the Christian missionaries, and when the belief in witchcraft had come in vogue, the Walpurgis-night obtained naturally a notorious significance, inasmuch as, during the night between April 30 and May 1, the witches were held to ride on broomsticks and he-goats to the old places of judgment and sacrifice, in order to enjoy themselves there with their master the devil. Such witch-hills were tolerably numerous in Germany and the neighboring countries. The best-known, however, was the highest point of the Harz, the Brocken, Brocks, or Brocksberg, which has obtained a wide celebrity as the scene of the witches' Sabbath in Goethe's *Faust.*

WALRUS. See MORSE.

WALSH, a co. in n.e. N. Dakota, on Red river; 1584 sq.m.; pop. '90, 16,587. Co. seat, Grafton.

WALSH, ROBERT, LL.D., 1784–1859; b. Baltimore; educated at the Jesuit college of Georgetown; studied law, but practised only a short time. He adopted literature as a profession, and in 1811 published the first American quarterly, the *American Review.* This meeting no great success was discontinued until 1827, when it was revived and edited by Walsh for 10 years. In the mean time he was editor of the *American Register,* the *National Gazette,* and the *American Magazine of Foreign Literature.* From 1845 to 1851 he was U. S. consul at Paris and correspondent of several American papers.

WALSH, The Most Rev. William J., R.C. archbishop of Dublin, Ireland; b. in Dublin in 1841; was educated at Maynooth college, Ireland. Completing his academic course in 1864, he spent three years in special ecclesiastical studies. In 1867, he became professor of theology at the college; in 1878, its vice-president, and on the death of Dr. Russell was unanimously chosen its president by the Irish bishops. He had great influence in framing the Land Act of 1881. By his exertions, a committee was appointed

to inquire into the Queen's college of Ireland. He was a senator in the Royal university of Ireland, and commissioner of national education in Ireland (1895). He was appointed to the see of Dublin (1885). He is the author of *Officium Defunctorum et Ordo Exsequiarum* (1884); *Bimetallism and Monometallism* (1893–6); *The Irish University Question* (1897).

WALSINGHAM, Sir Francis; English statesman, of an ancient Kentish family, third and youngest son of William Walsingham of Scadbury, was born at Chiselhurst, Kent, in 1536. He studied at King's college, Cambridge, and afterward traveled on the continent, where he remained until the accession of queen Elizabeth. Burleigh, with his usual discernment in selecting men of talent, discovered his abilities, brought him into office, and sent him on an embassy to France in August, 1570. He remained in Paris until April, 1573, and discharged diplomatic duties with such consummate skill that he was, on the recommendation of his great patron, appointed one of the principal secretaries of state to Elizabeth. He was also sworn of the privy council, and knighted. In 1578 he was sent on an important embassy to the Netherlands; in 1581 to France; and in 1583 to Scotland. He was, with some reason, regarded by the adherents of Mary, queen of Scots, as the most insidious of her enemies in the English council. He contrived to intercept most of her letters, and after having deciphered them, sent them to their destination, in order to obtain fresh intelligence from their answers. Some of these deciphered letters are preserved in the British museum. Walsingham soon held Mary secure in the toils. Some time previous to Sept., 1583, he had bribed to his service Cherelles, the secretary to the French ambassador Castelnau, in whom Mary placed implicit confidence. Walsingham also won over Gray, the envoy of the duke of Guise and other friends of Mary to James VI. (James I. of England), who employed him to manage his correspondence with his mother and his friends in France. The most secret letters of Mary and of James thus came into the hands of Walsingham. Up to Babington's conspiracy, or, as some have called it, Walsingham's conspiracy, there was no evidence for charging Mary with being accessory to any of the plots formed against the life of Elizabeth. The real fountain-head of this conspiracy, and the chief confederates, were spies in the pay of Walsingham, and all the correspondence of Mary and her friends passed into the hands of Elizabeth's dexterous minister. After the discovery and execution of Babington, etc., Walsingham went to Fotheringay as one of the commission to try queen Mary. She charged him with having forged the correspondence produced against her, when Walsingham rose in his place and solemnly called God to witness that he had not done anything unworthy of an honest man, and that he was wholly free from malice. Elizabeth signed her death-warrant with a jest on Walsingham's hatred of the queen of Scots. She had ordered Davison to bring her the warrant, and when she had signed it she said, "Go; tell all this to Walsingham, who is now sick; though I fear he will die for sorrow when he hears it." Walsingham was distinguished even among the ministers of Elizabeth for acuteness of penetration, extensive knowledge of public affairs, and profound acquaintance with human nature. His administration of foreign affairs was founded on the system of bribery, espionage, and deception. He is said to have had in his pay 53 agents and 18 spies, in various countries; and no minister was better informed of the intrigues of foreign courts. Notwithstanding this diplomatic duplicity, which was then universal among public men, Walsingham's personal integrity and disinterested patriotism are undoubted. He was of strict morals, favored the puritan party, and in his later days gave himself up to religious meditation. He retired from public affairs some time before his death, and resided at his house in Barn Elms, where he died April 6, 1590. Elizabeth was ready enough to acknowledge his diligence, genius, and important services, yet she kept him poor. There remain in the British museum (Harleian MSS.) various letters from Walsingham complaining of his being wholly unable, on his scanty appointments, to support his establishment, though very inadequate to his dignity of ambassador in France. Camden says he died so far in debt that he was buried privately by night in St. Paul's church, without any funeral solemnity. The queen was chary even in conferring honors upon him, for he received nothing but his knighthood, and held no offices when he resigned the charge of foreign affairs. He was married, and his daughter Frances became successively the wife of sir Philip Sidney, of the brilliant and unfortunate earl of Essex, and of the brave soldier, Richard de Burgh, 4th earl of Clanricarde.

WALTER, John, 1739–1812; b. England; was by trade a printer, and in 1780 obtained possession of two patents which Henry Johnson had received for an invention called logography, a method of printing with types containing whole words or syllables and various combinations, instead of single letters. He published, Jan. 18, 1785, the first number of the *London Daily Universal Register, printed logographically*, which, on Jan. 1, 1788, was issued as *The Times* or *Daily Universal Register*. The invention had no great success; but this paper, *The Times*, became the leading English daily journal.

WALTER, John, 1784–1847; b. London; son of John, the founder of the London *Times*. That paper, when he became its manager, in 1803, had a circulation of only 1000 copies. By 1813 it had increased to 5,000. In 1814 the *Times* began to be printed by steam. Walter was returned to parliament for Berkshire in 1832, resigned in 1837, and was elected for Nottingham in 1841.

WALTER, John, b. London, 1818; son of John. He was educated at Eton and Oxford, and called to the bar in 1847. He represented his father's borough of Notting

ham as a liberal-conservative, 1847–59; then was elected for Berkshire. He was defeated in 1865, but returned in 1868, 1874, and by a narrow majority in 1880. The *Times*, under his proprietorship, though successful, has scarcely maintained its former influence. He was a large land-holder. He died in 1894.

WALTER, Thomas Ustick, ll.d., b. Philadelphia, 1804; studied architecture. Among his designs are the Philadelphia co. prison, Girard college, the U. S. capitol extension, and the new treasury building. He long held the chair of architecture in the Philadelphia Franklin institute. He died in 1887.

WALTHAM, a city in Middlesex co., Mass.; on the Charles river and the Fitchburg and the Boston and Maine railroads; 10 miles w. of Boston. It was incorporated as a town in 1738, and as a city in 1884, and contains a public library, hospital, home for the feeble-minded, Leland home for aged women, high and graded public schools, Prospect Hill park, electric light and street railroad plants, water-works owned by the city, national and savings banks, and daily and weekly newspapers. The city is particularly noted for its extensive watch-making industries, also for its cotton mills, bleachery, and manufactories of electric clocks, hosiery, and crayons. Pop. '90, 18,707.

WALTHAM ABBEY, a market t. in the county of Essex, on the banks of the Lea, 12 m. n. of the e. part of London, on the Great Eastern railway. It contains a spacious Norman church, originally belonging to an abbey. The river Lea here divides into several branches, which are made to turn a number of gunpowder and flour mills belonging to government. Enfield Lock, at which is situated the celebrated government factory for rifles, etc. (see Small-arms, Factories, Royal), is about a mile distant; and many of the hands there employed live in and around Waltham Abbey. Pop. '81, 5368; '91, 6066.

WALTHER VON DER VOGELWEIDE, the greatest and most famous minnesinger (q.v.) of the Middle Ages, was b. 1165–70 in Franconia or in Austria. Although his family was noble, he had no possessions, and became a minstrel as much, perhaps, from necessity as from impulse. His master and early model was the elder Reinmar. It is thought that his first public performances in "singing and saying" date from about 1187; soon after which, he found a warm patron in Friedrich the Catholic, duke of Austria. But this prince having died in 1198, Walther began the life of a wandering minstrel, in the course of which he visited the courts of most of the German sovereigns. A few details of his career are known. He twice (1199 and 1205) spent some time at the court of the emperor Philip; and then lived six years at Eisenach with a generous patron, Hermann landgraf of Thuringia. During 1214–15 he repeatedly visited the emperor Otho, by whom, as well as by Philipp, he seems to have been treated with unkingly parsimony. From 1217 to 1219 he lived with duke Bernhard in Carinthia, then returned to Austria, and in 1220 received from Friedrich II. a small estate at Würzburg. He died about the beginning of 1228. His grave has long been pointed out in the Laurence garden of the cathedral of Würzburg; but a new monument was erected to him in 1843. Walther far excelled his master Reinmar, whom he survived about 20 years, both in matter and style; while in richness and versatility of mind all the other minnesingers must stand far behind him; for, to his wide sympathies and matured art, all themes were alike: tenderness and depth, no less than cheerfulness and gayety, deep earnestness, as well as playful raillery. He did not confine himself, like Reinmar, to minnelays, but wrote also hymns, eulogies of his patrons, and didactic pieces. He sang of the duties and dignities of the emperor; of the obligations of princes and vassals; of the rights and wrongs of the question between the pope and the emperor; of the glory of the true church; and often his song conveyed earnest and cutting censure. But it was only on conviction that he gave praise or blame, never influenced by favor or prejudice; and his censures of the church were those of a candid but pious believer. From a decided patriotic feeling, he stood firmly by the empire and the emperor in opposing the pretensions and usurpations of the pope. His writings on this subject had a widespread and powerful effect; they alienated, according to the testimony of a contemporary, Thomasin, thousands from the pope, and determined the politics, so to speak, of the German poets for the whole century. Walther was soon recognized by his contemporaries as the master of lyric poetry; and the traditions of the later minnesinger schools place him among the twelve who, in the emperor Otho the great's time, originated and established the noble art of minstrelsy. Lachmann brought out a masterly critical edition of Walther's writings (Berl. 1827, 3d ed. 1853); and Simrock an excellent translation (with explanations by Simrock and Wackernagel, 2 vols. Berl. 1833; 2d ed. Leip. 1853); Uhland wrote a beautiful account of his life and writings (*Walther von der Vogelweide, ein altdeutscher Dichter*, Stuttg. and Tüb. 1822); and Hornig, a complete *Glossarium* to his poems (Quedlinb. 1844).—See Reuss, *Walther von der Vogelweide* (1843); Daffis (1854), Opel (1860), Rieger (1863), Kurz (1863), and Menzel (1865).

WALTON, a co. in n.w. Florida, having the gulf of Mexico and Choctawhatchee bay on the s.; about 1360 sq.m.; pop. '90, 4816, chiefly of American birth, with colored. Co. seat, De Funiak Springs.

WALTON, a co. in n. Georgia; 389 sq.m.; pop. '90, 17,467, chiefly of American birth, inclu. colored. Co. seat, Monroe.

WALTON, Brian, d.d., 1600–61; b. England; graduated at Cambridge, 1619; rector of St. Martin's Orgar, London, 1626; and of Sandon in Essex, 1636. Being involved in

the troubles of the times he was deprived of his rectories; but undismayed, he planned the famous polyglot Bible for which £9,000 was subscribed. He had various learned helpers, but the editorship devolved on himself. The great work was finished in 4 years. It employs in all 9 languages. The four gospels are in six, and the rest of the New Testament in five. At the restoration he regained his preferments, and was consecrated bishop of Chester in 1660.

WALTON, George, 1740–1804; b. Va.; studied law, and was admitted to the Georgia bar, 1774. He took an active part in the events which led to the revolution; 1775–81, a delegate to congress; at the defense of Savannah was wounded and made prisoner. He was twice governor of Georgia; chief-justice of the state, 1783; judge of the U. S. supreme court, 1793; and U. S. senator, 1795–96. He was one of the signers of the declaration of independence.

WALTON, Izaak, author of the *Complete Angler*, was the son of one Jervis Walton, a yeoman, and was born at Stafford on Aug. 9, 1593. Of his earlier life not much is certainly known. In the year 1624 we find him settled in Fleet street, London, and carrying on business there as a hosier. In the end of 1626 he married Rachel Floud, a descendant of Archbishop Cranmer. From George Cranmer, her uncle, who had been a pupil and friend of Hooker, it is thought likely that Walton derived much of the material for his life of that eminent man. In Aug., 1640, she died in giving birth to a daughter, having before had two sons, neither of whom survived her. In 1643 Walton retired from business with such a modest competence as sufficed for the simple way of life he affected; and in 1647 he married a second time. The lady was Anne Kenn, half-sister of the well-known bishop of that name. She bore to him a daughter and two sons, only one of whom lived, and died in 1662, to the great grief of her husband, who survived her many years. He died on Dec. 15, 1683, at the great age of 90, in the house of Dr. Hawkins, his son-in-law, prebendary of Winchester cathedral, and was buried in the vault of that sanctuary.

With the celebrated Dr. John Donne, who died in 1631, Walton, who attended his ministry, had been on terms of affectionate intimacy; and on the publication of his sermons in 1640 he was induced to preface them with a life of the author. This, his first publication, was followed by lives of Hooker, Sir Henry Wotton, and George Herbert, in succession; the whole four being reissued in a collected edition in 1670. In 1678 the life of his friend, Bishop Sanderson, was added. *The Complete Angler, or Contemplative Man's Recreation*, was published in 1653. A fac-simile of the original edition was published in 1876, and since the first, nearly a hundred editions have appeared. To the edition of 1676 a little treatise on fly-fishing was added by Walton's friend, Charles Cotton, in a fishing-house built by whom, on the banks of the river Dove, many of the later days of his happy and blameless life lapsed peacefully in the pursuit of his favorite recreation. *The Complete Angler*, as a treatise on the art of angling, may be regarded as in good part obsolete, but it continues and will continue to be read for its charming simplicity of manner, its pastoral freshness and poetry, and the pure, peaceful, and pious spirit which is breathed from its quaint old pages. The *Lives*, though somewhat less widely known, are in their kind not less exquisite and unique. Wordsworth has dedicated to them a beautiful sonnet. Up to 1883 there had been issued ninety-seven editions of *The Complete Angler*. Among the best are those of Hawkins (1760), Nicolas (1836), Bethune (N. Y. 1847), Dowling (1857), and the fac-simile of the original edition. See the Life of Walton by Dowling (1884), and an article in *Scribner's Magazine* for September, 1893.

WALTZ (Ger. *Wälzer*, literally, roller), a national German dance, said to have originally come from Bohemia. It first became a fashionable dance in the other countries in the early part of the 19th century. It is danced to music of $\frac{3}{4}$ time by any number of couples, who, with the gentleman's right arm round his partner's waist, wheel rapidly round on an axis of their own, advancing at the same time round the room. Some time ago the *valse à deux temps* was generally adopted—a form of the waltz not so graceful as the older one, because not so correspondent to the rhythm of the music—but this has now given place to the *valse à trois temps*.

WALWORTH, a co. in n. S. Dakota, having the Missouri river for its w. boundary; about 740 sq.m.; pop. 1890, 2153, chiefly of American birth. Co. seat, Bangor.

WALWORTH, a co. in s. Wisconsin, containing Geneva lake, 9 m. long; 570 sq.m.; pop. '90, 27,860, chiefly of American birth, with colored. Co. seat, Elkhorn.

WALWORTH, Reuben Hyde, ll.d., 1789–1867; b. Conn.; lived on a farm, taught school, and in 1809 was admitted to the bar. He began to practice at Plattsburg, and soon rose to a high rank in his profession. During the war of 1812 he was adjt.gen. of the state militia, and took part in the operations about Plattsburg. He was a master of chancery, and served in congress, 1821–23. He became a justice of the circuit court in 1823, and was chancellor of the state, 1828–48. His decisions are reported in Hill, Wendell, Denio, Barbour, and Page. His rank as an equity judge was high. He published *Rules and Orders of the New York Court of Chancery* (1829); and *Hyde Genealogy* (1864).

WAMPUM, a name given to shells and shell-beads, used as money, and worn for ornaments in strings and belts by the North American Indians.

WANAMAKER. John, b. Philadelphia co., Penn., 1838; received a common school education; entered mercantile life in Philadelphia, and built up the largest retail business in the U. S. He originated the Wanamaker system of retail business, one notable feature of which is the return of money for goods purchased upon the return of the goods by a dissatisfied purchaser. He was a member of the Centennial exhibition board, and chairman of the Bureau of Revenue. He is very active in Christian and philanthropic work, and is pres. of the Young Men's Christian assoc. in Philadelphia. He declined the nomination for congressman-at-large, 1883. In 1889 he became postmaster-general in Pres. Harrison's cabinet. In 1896 he opened in N. Y. city the store built by A. T. Stewart.

WANDERING JEW, The. The legend of the wandering Jew, who cannot die, but, as the punishment of his sin, is obliged to wander over the face of the earth till Christ shall pronounce his doom at the last day, seems to have originated in that passage of the gospel of St. John (xxi. 22) where Jesus says of John: "If I will that he tarry till I come, what is that to thee? follow thou me. Then went this saying abroad among the brethren, that that disciple should not die." It arose, probably, in the 13th c., when it is first related by Matthew Paris, and may be supposed to indicate the Jewish people, scattered throughout the world, and nowhere finding a home. According to the current legend, the wandering Jew is Ahasuerus, the shoemaker at Jerusalem, who, when the Saviour wished to rest before his house, on his way to Golgotha, drove him away. Another legend states him to be Pilate's door-keeper, Kartaphilus, who struck Jesus on the back as he led him out of his master's judgment-hall. So recently as the last century impostors took advantage of the belief in this legend, and gave themselves out for the wandering Jew; and people were not wanting who, from time to time, maintained that he had appeared to them under different forms. A popular book relating in detail the history of the wandering Jew has been repeatedly printed in the German, French, Dutch, and Latin languages. The legend has likewise been frequently worked up in a poetical form, as by A. W. von Schlegel in the romance entitled *Die Warnung;* by Schubert in his poem of *Ahasuer;* by Goethe in *Aus meinem Leben;* by Mrs. Norton in *The Undying One* (Lond. 1842); and by Eugène Sue in his *Le Juif errant.* Compare Grässe, *Die Sage vom Ewigen Juden.*

WANDEROO', a name which has been given to several species of monkey. The species commonly described under the name is *macacus silenus* or *silenus veter*, a native of the coast of Malabar, a monkey of rather large size, deep black throughout, except a ruff of long gray or white hair, from the midst of which the face looks forth, and which descends over the chest, giving the animal a very peculiar aspect. This monkey exhibits considerable intelligence and docility, and performs its tricks with an absurd air of gravity.—The name wanderoo, however, more properly belongs to monkeys of the genus *presbytes*, natives of Ceylon, to which it is given by the Singhalese, and appears to have been transferred by mistake to the species just described, which is not found in Ceylon. The wanderoos of Ceylon are all small monkeys. The best-known species is *presbytes cephalopterus*, found in the low parts of the island. It feeds chiefly on the berries and buds of trees, and is seldom seen on the ground. Twenty or thirty are generally found together in a troop. When alarmed, they display marvelous agility in leaping, or rather swinging from branch to branch, using their powerful arms alternately, often flinging themselves obliquely so as to catch the lower bough of an opposite tree, and taking advantage of its rebound to carry them up again till they can reach a higher branch; the females, all the while, being often encumbered by their young, which cling to them. This monkey is far from being so mischievous as monkeys in general. "In captivity it is remarkable for the gravity of its demeanor, and for an air of melancholy in its expression and movements which is completely in character with its snowy beard and venerable aspect."—Tennent's *Ceylon.* Its disposition is extremely gentle and affectionate; it is intelligent and docile, and very cleanly in its habits.—Several other species of wanderoo or *presbytes* are found in Ceylon, some of them in the more elevated parts of the island.

WANTAGE, a market-t. in Berkshire, in the vale of the White Horse, 13 m. s. w. of London, and 60 w. of London. It manufactures agricultural implements, and has an extensive trade in corn. It was the birthplace of Alfred the Great and of Bishop Butler. Pop. '81, 3488; '91, 3669.

WAPELLO, a co. in s.e. Iowa, drained by the Des Moines river; 432 sq.m.; pop. '90. 30,426. Co. seat, Ottumwa.

WAP'ENSHAW (Sax. *wæpen*, weapon, and *sceawan*, to show), a periodical gathering of the people, instituted by various Scots statutes, for the purpose of exhibiting their arms, these statutes directing each individual to be armed on a scale proportioned to his property. There are numerous Scots acts of the 15th and 16th centuries, regulating the subject of wapenshaws. In the time of war or rebellion, proclamations were issued charging all sheriffs and magistrates of burghs to direct the attendants of the respective wapenshawings to join the king's host. During the reign of the later Stuarts, atten-

dance on the wapenshaws was enforced with considerable strictness; and in addition to military exercises, sports and pastimes were carried on by authority at these gatherings.

WAP'ENTAKE (Sax. *wæpen*, arms, and *tac*, touch), a name given in Yorkshire to the territorial divisions of the county, similar to what, in most of the other counties of England, are called *hundreds*, and, in the more northern counties, *wards*. The term has come down from Anglo-Saxon times, where it, in the first instance, signified the assemblies of each district held for the administration of justice and like purposes, at which each vassal attended armed, and "touched" the spear of his overlord, in homage.

WAPITI, *Cervus Canadensis*, a species of deer, nearly allied to the stag, but considerably exceeding it in size, being 4½ feet in height at the shoulder. It is a native of North America, found as far s. as Carolina, and as far n. as 56° or 57° n. lat. It is yellowish brown on the upper parts; the sides gray; a pale yellowish patch on each buttock, bounded by a black line on the thigh; the neck, a mixture of red and black, with long, coarse, black hair, falling down from it in front like a dewlap; a black mark at each angle of the mouth. The hair is crisp and hard, but there is a soft down beneath it. The antlers are large, much like those of the stag, but the first branch bends down almost over the face. The wapiti is called *elk* and *gray moose* in some parts of America, although very different from the true elk, or moose deer.

WAPPERS, Gustave; 1803–74; b. Antwerp; studied art in Flanders and at Paris, and became a historical painter of the romantic style. By Leopold I. he was made a baron and director of the Antwerp academy. In 1855 he removed to Paris, where the rest of his life was spent. His best works are, "Christ at the Sepulcher," "Charles IX. on the night of St. Bartholomew," "Execution of Anne Boleyn," and "The Great Fishery of Antwerp."

WAPPINGER, a town in Dutchess co., N. Y.; on Wappinger's creek and the Poughkeepsie and Wappinger's Falls electric railroad; 8 miles s. of Poughkeepsie. The village of Wappinger's Falls is partly in each of the towns of Poughkeepsie and Wappinger, and has Union school No. 1, a graded school, the Grinnell public library, public park, savings bank, print works, various manufactories, and a weekly newspaper. The creek here falls 94 feet to tidewater, and besides beautiful scenery provides excellent power for manufacturing. Pop. '90, town, 4575; village, 3718.

WAR between states or nations, or between parties in the same state (*civil war*), is analagous to club-law (Ger. *faustrecht*), or the law of the strongest, among the individuals of a community, which is the normal state of things where no legal or fixed rights are established, or where there is no authority to enforce them. The prevalence of war among nations is thus an indication of the imperfection, or the total want, of international law. If the sentiment of brotherhood were universally diffused, and a system of international morality established and generally accepted, together with an organization for putting it in force, we can conceive the necessity for war to cease. And although the full realization of this state of things may never be attained, it is nevertheless the ideal goal to which all real progress tends. But it by no means follows that in the present condition of the world, while the sentiment of international justice is yet in embryo, peace at any price is to be preferred to war. When a community is in a state of anarchy, the individual man must take the law into his own hands, and defend his life and his rights with violence if need be; and nations in similar circumstances must do the same. The balance of power (q.v.), the shape in which the sentiment of political morality in Europe seemed at one time trying to crystallize itself, has gone again apparently into chaos.

Wars are various in their occasions and objects, sometimes breaking out in consequence of disputes about territorial possessions or material interests; at other times, having reference to the establishment of some important point of civil or religious liberty. In all cases, the aim of each contending party is to weaken and overthrow the opposing party. At one time the art of war was supposed to consist very much in wearing out the enemy by a slow process of exhaustion, and thus wars were much protracted; but more recently the greatest generals have adopted the method of rather endeavoring to strike sudden and terrible blows, by which the war is sooner brought to a termination; and this method, although it may often have been adopted without regard to considerations of humanity, is, in all probability, less productive of suffering to mankind than the other.

Among rude nations, wars are conducted by tumultuary hosts, suddenly congregated, and in general, either after defeat or victory, soon dispersed. But the wars of the more civilized and powerful nations have long been conducted by armies carefully trained and disciplined; and in the case of maritime powers, by means of fleets at sea as well as of armies on land. Preparation for war among such nations requires not only the forming and training of the army, but vast provision in many various ways of the means and *matériel* of war. Much science and skill are also applied to the conduct of military operations, and the principles upon which they ought to be conducted have been carefully investigated, and theories tested by an examination of the history of the most important campaigns. See Strategy, Tactics.

In the progress of society, certain *usages of war* have come to be generally recognized. These, of course, have varied at different times, and in different parts of the world, according to the state of civilization and the prevalent feelings of the time; they are also subject to modification from causes less general. But the changes which have taken

place in them during the lapse of ages have been in general favorable to the interests of humanity. Prisoners of war are no longer put to death, nor are they reduced to slavery, as was once very frequently the case, but their treatment has become generally more and more mild and kind. It is a well-understood rule, however, that a prisoner of war obtaining his liberty by exchange or otherwise, with the condition of not serving again during a fixed period against the same power, forfeits his life if he is found so serving and is again taken prisoner. Amongst all civilized nations, quarter is granted in battle whenever it is sought; and there are certain usages universally prevalent with regard to the capitulation of fortified places, and of bodies of troops hopelessly hemmed in by superior forces, etc.

War-cries for mutual recognition and encouragement in battle have always been common, each rude nation or tribe having its own. The ancient war-cry of the English was *Saint George!* that of the Spaniards, *San Jago!* and that of the French, *Mountjoie Saint Denis!* In the feuds of the middle ages, each party, or the retainers of each noble family, had a distinctive war-cry. Sometimes the war-cry was the name of the family. Thus, in Scotland, the retainers of the noble houses of Douglas and of Home rushed into battle with the cry of *A Douglas! a Douglas!* or *A Home! a Home!* The French armies under Napoleon were accustomed to charge with shouts of *Vive l'Empereur!*

The invention of gunpowder has effected great changes in the whole art of war; but the introduction of fire-arms has rendered battles less sanguinary and ferocious than they previously were. While fire-arms were yet unknown, warlike engines of various kinds were employed; but close combat was more general, and often more protracted, and the passions of the combatants had thus in ordinary battle more of that exasperation which fearfully characterizes the storming of a town. See INTERNATIONAL LAW.

In the United States, the war department is an executive department of the government, having charge of all the military affairs of the country, and was established by act of Aug. 7, 1789. The secretary of war is its head, and the first to fill the office was Henry Knox. The secretary of war has custody of all records, etc., relating to the army, superintends purchases of military supplies, directs army transportation, distributes stores, etc., has charge of the signal service and meteorological records, disburses appropriations for rivers and harbors and for their survey and improvement, and superintends and supplies arms and munitions of war. An annual report of all contracts, appropriations, disbursements, etc., is submitted to congress by the secretary of war. The correspondence and accounts are in charge of the chief-clerk of the war department. Ten military bureaus compose the department, each having at its head an officer of the regular army, who receives a salary of $5000 while thus employed. The bureaus are those of the adjutant general, the inspector general, the quarter-master general, the commissary general, the surgeon general, the paymaster general, the chief of engineers, the chief of ordnance, the chief signal officer, and the judge advocate general. More than 1400 clerks and other assistants are employed. The expenses of the department in 1890, including appropriations for rivers and harbors, were $44,582,838.08.

WARASDIN', capital of a co. in the Austrian kingdom of Croatia, upon the right bank of the Drave, and 28 m. n.n.e. of Agram. It is to some extent fortified, is surrounded by straggling suburbs, and contains several Catholic churches, two convents, and a gymnasium. Silk-spinning is carried on; and stoneware, wine, and tobacco are manufactured. Pop. '90, 11,055.

WARBECK, PERKIN. See HENRY VII.

WARBLER, a popular name often applied to all the birds of the family *sylviadæ* (q.v.), many of which, however, commonly receive other popular names, as the black cap, nightingale, hedge-sparrow, redbreast, redstart, stone-chat, wheat-ear, white-throat, etc. (q.v.), while many receive the name warbler with some adjunct. Several British species, commonly thus designated, belong to the genus *salicaria*, others to the genus *sylvia*. The species of the former genus have the tail rounded; in the latter, it is almost square or a little forked. The *salicariæ* are also inhabitants of moist situations, whence they are known as *sedge warblers* and *reed warblers;* the *sylviæ* are inhabitants of woods. Of the former genus is the GRASSHOPPER WARBLER (*salicaria locustella*), not unfrequent in many parts of England, and found also in the s. of Scotland and in Ireland. It is found in most parts of the center and s. of Europe, at least during summer, being partially a bird of passage. It is of a greenish-brown color, the centers of the feathers dark brown, producing a spotted appearance; the lower parts pale brown. It is a shy bird, hiding itself in hedges and bushes, but very active, often darting out like a mouse from the bottom of the hedge, and receives its name from its chirping, grasshopper-like note.—The SEDGE WARBLER (*salicaria phragmitis*) is the most common British species of *salicaria*, and is generally found in thick patches of reeds or willows in marshes, or in other situations close to water, and where the aquatic herbage is thick and strong. It abounds on the marshy banks of the Thames. It is of a brown color, exhibiting various shades, finely intermixed; the chin and throat white; the under parts buff color.—The REED WARBLER (*salicaria arundinacea*) is found in summer in marshy situations in the s. of England; it abounds in Holland and in many parts of Europe, and its range extends to the n. of India. It is of a uniform pale brown, with a tinge of chestnut; the chin and throat white; the under parts pale buff color. Its nest is

remarkable; it is attached to the stems of three or four reeds, and formed by winding the branches of their panicles together with a little wool; and is conical and deep, so that the eggs or young may not be shaken out when the reeds are shaken by the wind. —The WOOD WARBLER, also known as WOOD WREN (*sylvia sylvicola*), is common in the wooded districts of England in summer, particularly in old plantations of oak and beech. It is olive green, tinged with yellow, the wings brown, the primaries and secondaries edged with bright yellow, the tertials with a broader edge of yellowish white; the lower parts yellow and white.—The WILLOW WARBLER (*sylvia trochilus*), is very common in the s. of England in summer, but more rare in northern parts of Britain. It frequents woods, shrubberies, thick hedgerows, and bushes; but builds its nest on the ground. It is of a dull olive-green color, the wing and tail feathers dark brown, the wing-feathers edged with green; the under parts whitish, slightly tinged with yellow. The tail is slightly notched. There are other British species of more rare occurrence.—Numerous species of warblers are found in North America, migratory birds, which spend the winter in more southern regions. Not a few of the same species are therefore reckoned among the birds of the West Indies. Some of the European species are in like manner found in Africa; and Asia has many species of warblers, among which some of the European species are included. Australia has many species of warblers, some of which are of very beautiful plumage.

WARBURTON, ELIOT BARTHOLOMEW GEORGE, 1810–52; b. Ireland; educated at Cambridge; admitted to the bar, but devoted himself to the care of his estates in Ireland, to travel and literary pursuits; traveled in the east, 1843, and published on his return, *The Crescent and the Cross, or Romance and Realities of Eastern Travel.* He settled in London, and published: *Reginald Hasting*, a romance; *Memoir of Horace Walpole and his Contemporaries; Hochelaga; Darien, or the Merchant Prince*, a historical romance. While on a voyage to the West Indies in 1852 he perished in the burning of the steamer *Amazon* off Land's End.

WARBURTON, WILLIAM, a distinguished English divine, commonly known as bishop Warburton, was born at Newark, in the county of Nottingham, on Dec. 24, 1698. He was the eldest son of George Warburton, an attorney of that place, who claimed descent from an old Cheshire family. Young Warburton received his education at the school of his native town, and afterward at Oakham in Rutlandshire, which he left in the year 1714, returning home to pursue the profession of his father, who had died some years before. Having served the necessary apprenticeship, he practiced as an attorney at Newark for some years, but with no distinguished success. His natural bent was toward literature; and he had all along expressed a desire to take orders in the church of England. Finally, he quitted the legal profession with this object in view; and having gone through the necessary course of study, he was presented by sir Robert Sutton, in 1728, to the rectory of Brand-Broughton, in the diocese of Lincoln, where he remained for many years. After publishing some comparatively unimportant pieces, he issued, in 1736, a treatise, entitled *The Alliance between Church and State, or the Necessity and Equity of an Established Religion and a Test Law.* This work, which is still recognized as one of the most masterly statements of the subject from the point of view of the writer, drew great and immediate attention; and in January, 1737–38, it was followed by the first volume of the *opus magnum*, on which his fame as a theologian must mainly continue to rest. This celebrated work, *The Divine Legation of Moses, demonstrated on the Principles of a Religious Deist, from the Omission of the Doctrine of a Future State of Rewards and Punishments in the Jewish Dispensation*, though it encountered a storm of adverse criticism, to which the writer thought it necessary to reply in *A Vindication*, etc., at once established the position of Warburton as one of the most potent intellects of the period; and though its main argument has since been extensively discredited as more or less "precarious," not the less the book, in virtue of its vast learning, its vigor, and originality, will always maintain its reputation as one of the masterpieces of the great period of our English theology. In 1739, a new and revised edition of the first part of the work appeared. This was followed, in 1741, by the publication of the second part; and the third and concluding section, rather supplementary to the argument than essential to it, was only given to the world after the death of the writer.

Becoming involved in the controversy which followed the appearance of Pope's *Essay on Man*, Warburton undertook the defense of the poet, and, in 1739–40, issued a series of seven letters, entitled *A Vindication of Mr. Pope's Essay on Man, by the Author of the Divine Legation.* The poet was much gratified; and between him and his vindicator a warm friendship was the result, which only terminated with the death of Pope, in 1744. He died, bequeathing to Warburton one-half of his library, and such profit as might accrue from any edition of his works published after his death. To Pope, Warburton was indebted for opportunities of cultivating the friendship of some of the most distinguished men of the time—among others, of the well-known Ralph Allen, of Prior park, near Bath, to whose niece, Miss Gertrude Tucker, he was married in 1745.

Though Warburton's important services to literature and religion were admitted, they did not for a long time bring him any very great recognition in the way of substantial preferment. On the appearance of *The Divine Legation*, indeed, he had been appointed

chaplain to the prince of Wales; and in 1746, nearly ten years later, the society of Lincoln's inn unanimously elected him to be their preacher. In 1757, he was promoted to the deanery of Bristol; and finally, in 1760, Mr. Pitt, afterward earl of Chatham, bestowed on him the bishopric of Gloucester, declaring that "nothing of a private nature, since he had been in office, had given him so much pleasure" as this exercise of his patronage. In the later years of his life his mind became seriously impaired; and he was utterly prostrated by the loss of his only son, whom he did not long survive. He died on June 7, 1779.

Warburton was a keen polemic, and deeply engaged in all the intellectual warfare of his time. In nearly everything he wrote, there is the impress of a vigorous and fertile mind, with an arrogance of tone, which tends, in his treatment of adversaries, to degenerate into truculence and scurrility. In addition to those already mentioned, it seems sufficient to give the titles of a few of his more notable performances. In 1750 appeared his *Julian, or a Discourse concerning the Earthquake and Fiery Eruption which defeated that Emperor's Attempt to rebuild the Temple at Jerusalem, apropos* of Dr. Middleton's *Inquiry concerning the Miraculous Powers of the Christian Church.* Shortly after came two volumes entitled *The Principles of Natural and Revealed Religion occasionally Opened and Explained;* and in 1755, *A View of Bolingbroke's Philosophy, in a Series of Letters to a Friend,* which was held to be much the ablest of all the answers to Bolingbroke which appeared. In 1757, he attacked Hume, in a publication entitled *Remarks on Mr. David Hume's Natural History of Religion by a Gentleman of Cambridge, in a Letter to the Rev. Dr. Warburton.* The blind deceived no one; and if we may estimate the success of the attack by the annoyance it gave the philosopher, his allusion to "that low fellow Warburton" may be held to indicate success. In 1747, he went somewhat out of his way to issue an edition of Shakespeare, with notes critical and emendatory, which last, though ingenious, and occasionally happy, did not greatly add to his reputation. A complete and splendid edition of his works was published in 1788, at the expense of his widow, by his friend, bishop Hurd, who prefaced it with a biography.

WARD, in law, in the feudal system, the minor heir of a tenant *in capite* of the king. The expression was extended to all minors under guardianship. A ward under guardianship can bind himself by contract only for necessaries. The guardian stands *in loco parentis* to his ward. The ward is entitled to an account by the guardian of the latter's administration of the estate. See GUARDIAN.

WARD, a co. in N. Dakota, incorporated 1885; 1512 sq.m.; pop. '90, 1681. Co. seat, Minot.

WARD, a co. in w. Texas; 1160 sq. m.; pop. '90, 77. Co. seat, Barstow.

WARD, ARTEMAS, 1727–1800; b. Mass.; American gen. He was graduated at Harvard in 1748, was a member of the colonial legislature and council, and was justice of the court of common pleas in Worcester co. He served in the French and Indian war as lieut.-col. under Abercrombie, and when the revolutionary war broke out, was appointed first maj.-gen. by congress, and as such commanded the army at the siege of Boston, until Washington was elected commander-in-chief, when he was made second in command. He resigned in Apr., 1776. He was 16 years in the Mass. legislature, and in congress from 1791–95.

WARD, ARTEMUS. See BROWNE, CHARLES FARRAR.

WARD, EDWARD MATTHEW, R.A., an eminent painter of the present century, was b. in the year 1816, in London. He early displayed a taste for art, and was educated in a way to develop it. In 1834 he was sent to study at the Royal academy; and two years after, he went to Rome, where he remained for some time, gaining, in 1838, a silver medal, given by the academy of St. Luke. He returned to England in 1839, making on the way a short visit to Munich, where he studied under Cornelius. He was a royal academician in 1856 and died, 1879.

WARD, ELIZABETH STUART PHELPS. See PHELPS, ELIZABETH STUART.

WARD, GENEVIEVE (Countess Guerbel), b. New York, in 1833. She studied music in New York and Italy; married Count Constantine Guerbel, a Russian officer, and made her first appearance in public under the name of Guerrabella at Milan, 1859. She sang with great success in various operas in Italy, France, and England; and came to America, 1862. Shortly afterwards she lost her voice through illness. Compelled to earn her living, she for a while gave music lessons, and then studied for the stage, making her début with success as "Lady Macbeth" at the Theatre Royal, Manchester, England, 1873. Her most famous part was that of "Stephanie" in *Forget-Me-Not.* She went to England in 1888 and later joined Irving's company.

WARD, HENRY AUGUSTUS, b. N. Y., 1834; educated at Williams college and at the Lawrence scientific school, Cambridge, where he was for some time Prof. Agassiz's assistant in zoölogy. He subsequently studied in Paris and Freiberg; traveled extensively in the east and in Africa, exploring the river Niger. As a mining engineer he was employed in the far western states, and visited South America and the West Indies; he was also naturalist to the Santo Domingo expedition of 1871. From 1861 to 1866 he was professor of natural sciences at Rochester university, where he established extensive collections of fossils and geological specimens.

WARD, JAMES, 1769–1859; b. London; began life as an engraver; became a painter of the school to which Morland belonged, whom he is said to have copied; member of the academy, 1811. "The Alderney Bull, Cow, and Calf," in the National Gallery, is considered a masterpiece. He excelled as a painter of rural subjects.

WARD, JOHN QUINCY ADAMS, b. Ohio, 1830; studied medicine, but in 1850 entered the studio of H. K. Brown, the sculptor, and after studying art there for six years, went to Washington, and in 1861 opened a studio in New York. Among his works are the bronze statues in Central park, "Shakespeare," "Private of the Seventh Regiment," "Fitz-Greene Halleck," "The Pilgrim," the "Indian Hunter," "Poetry," etc.; statues of Horace Greeley, H. W. Beecher, etc.; bust of A. W. Holley. In 1872 he was made president of the National Academy of Design. In 1893 he was one of the founders of the National sculpture society and became its first president.

WARD, MARY AUGUSTA ARNOLD (Mrs. HUMPHRY W.), b. Hobart, Tasmania, 1851; the eldest daughter of Thomas Arnold, M.A., of University coll., Oxford, and granddaughter of Thomas Arnold, D.D., of Rugby. She was married in 1872 to Thomas Humphry Ward, fellow of Brasenose coll., Oxford, author, and editor of a standard edition of *The English Poets*. She now resides in London. Her first work, *Milly and Olly*, a book for children, appeared in 1881. In 1884 she pub. *Miss Bretherton*, a novel; in 1885 a translation, with introduction, of Amiel's *Journal Intime*, and in 1888, the powerful novel, *Robert Elsmere*. She has contributed to the leading English quarterlies on the literature, politics, and art of European countries; to *The English Poets*, above mentioned, etc. In 1892 appeared *David Grieve*, in 1894 *Marcella*, and in 1895 *The Story of Bessie Costrell*.

WARD, NATHANIEL, 1578–1652; b. England; graduated, Cambridge, 1603; bred a lawyer; traveled on the continent; studied theology; rector of Standon Massye, Essex, 1626; suspended by Laud for non-conformity, 1633; came to America, 1634; colleague pastor of Thomas Parker, and afterward of John Norton, at Ipswich, 1634–37; published *Body of Liberties*, the first code of laws enacted in New England, adopted, 1641; took part in the settlement of Haverhill, Mass., 1640; returned to England, 1646; pastor of Shenfield, 1648. He published *The Simple Cobbler of Agawam*, a politico-religious satire; *Mercurius Anti-mechanicus, or the Simple Cobbler's Boy with his Lap-full of Caveats*. He was a famous wit, and something of a poet.

WARD, SAMUEL, 1725–76; b. R. I.; son of Richard, governor of Rhode Island. He served in the assembly of the colony, 1756–59; was chief-justice, 1761; governor, 1762 and 1765–67. He was a member of the committee of correspondence, and of the congress at Philadelphia in 1774–75. He was one of the founders of Brown university.

WARD, SAMUEL, 1756–1832; b. R. I.; educated at Rhode Island college. He accompanied Arnold's expedition against Quebec in 1775; was captured, and remained a prisoner till 1776. He afterward served in New Jersey and elsewhere. Settling in New York, he became a merchant and acquired a considerable fortune. He was a member of the Hartford convention.

WARD, WILLIAM, 1769–1823; b. England; was a printer, studied theology; became a Baptist preacher; was sent by the Baptist missionary society as a missionary and printer to India, 1799; forbidden by the East India company to remain at Calcutta, he settled at Serampore; printed the Bengalee New Testament and other translations of Dr. Carey; visited England, Holland, and the United States, 1819; returned to Serampore, 1821. He published, besides other books, *An Account of the Writings, Religion, and Manners of the Hindus, including Translations from their Principal Works*.

WARD, WILLIAM HAYES, D.D., LL.D., b. Mass., 1835; graduated at Amherst coll., 1856, and Andover theological seminary, 1859; ordained a Congregational minister, 1859; supplied two churches in Kansas; teacher of natural science, Beloit college, 1857–58; and in Utica free academy, 1862; professor of Latin, Ripon college, Wis., 1865; became a member of the editorial staff of the New York *Independent*, 1868; superintending editor, 1870, which position he still occupies. Dr. Ward has given special attention to oriental studies, has read valuable papers before the American oriental society, and contributed articles in the *Bibliotheca Sacra* on Assyriology: in these departments he has made extensive research, and holds high rank among scholars.

WARDEN, an officer appointed for the naval or military protection of some particular district of country. In order to keep the districts of England adjoining to Scotland and Wales in an attitude of defense, great officers, called lords wardens of the marches, were appointed, to whom the duty of protecting the frontier was committed. From this source originated the name *ward*, applied to the subdivisions of the counties of Cumberland, Westmoreland, and Durham—a term afterward extended to divisions of a city, town, or burgh adopted for municipal purposes. The custodier of Dover castle was created by William the Conqueror warden of the Cinque ports (q.v.), and guardian of the adjacent coast; an office comprising extensive jurisdiction, civil, naval, and military, the greater part of which was taken away by 18 and 19 Vict. c. 48.

WARDEN. See CHURCH WARDEN.

WARDHOLDING, the military tenure of land in Scotland under the feudal system, by which the vassal was bound to serve the superior in war whenever called on to do so. As the military duties of the vassal could not be performed when he was under age, the

superior had a right both to the guardianship of his person and to the possession of his fee during his minority. An arrangement, however, was frequently made by which this right was commuted into an annual payment, in which case the fee was said to be held in *taxed ward.* When an unmarried vassal succeeded, the superior was entitled to a sum proportionate to the value of the estate, called the *avail of marriage;* and a larger sum, called the *double avail of marriage,* was due when the superior named a wife for his vassal, and the vassal, rejecting her, married another woman. If a vassal alienated his lands or the larger portion of them without consent of his superior, the fee fell to the superior by what was called the casualty of *recognition,* which was a check on vassals impoverishing themselves to such an extent as would render them unfit to perform feudal services. Wardholding was abolished by 20 Geo. II. c. 50, as a system hazardous to the public tranquillity.

WARDIAN CASES, close glass cases placed upon a trough containing soil, and accurately fitted to it, intended for the growth of plants in the windows of apartments.

WARDLAW, Ralph, d.d., b. 1779, a celebrated preacher and theologian in the roll of Scotch Independents, was a seceder by extraction, and studied in connection with the Associate Secession church. Before he had completed his curriculum, however, he had convinced himself that congregational independency was the scriptural system of church government. In 1800 he began to preach, and after some time settled in Glasgow as pastor of an Independent church. In 1811 he was appointed professor of theology to the Congregational body in Scotland, in conjunction with the Rev. Greville Ewing; an office he retained, along with his pastorate, to the period of his death, which happened on Dec. 17, 1853. Wardlaw's life was a very laborious and earnest one. Besides discharging faithfully and ably the duties of the pulpit and the professor's chair, he was a voluminous author, often involved in theological controversy, and a prominent actor in the public religious and philanthropical movements of the day. His intellect was acute, his understanding sound, and his style remarkable for its perspicacity, vigor, and grace. The most important of Wardlaw's works are: *Discourses on the Socinian Controversy* (1813); *Lectures on Ecclesiastes* (2 vols. 1821); *Essays on Assurance of Faith, and on the Extent of the Atonement and Universal Pardon* (1830); *Discourses on the Sabbath* (1832); *Christian Ethics* (1833); *Discourses on the Nature and Extent of the Atonement of Christ* (1843); *The Life of Joseph and the Last Years of Jacob* (1845); *Congregational Independency* (1848); *On Miracles* (1852), *Lectures on Systematic Theology* (1856).—See *Life and Correspondence of Ralph Wardlaw*, by Dr. Alexander (1856).

WARDSHIP, in English feudal law, was the guardianship which the feudal lord had of the land of his vassal while the latter was an infant or minor. Until the majority of the infant, the lord, out of the profits, provided a fit person to render the services incumbent on the vassal. See Tenure, Wardholding.

WARD'S ISLAND, a nearly circular island within the corporate limits of New York city, in the East river near its junction with Harlem river. It forms the n. boundary of Hell Gate. It contains about 200 acres, much of which is finely wooded. An extensive insane asylum for males is under the control of the New York commissioners of public charities and correction, while the commissioners of emigration have charge of the state emigrant hospital, lunatic asylum, houses of refuge and nursery or home for children. There is also on the island a home for invalid soldiers who served in the city regiments.

WARE, a co. in s. Georgia, containing Okefinokee swamp in the s. portion; 893 sq. m.; pop. '90, 8811. Co. seat, Waycross.

WARE, a town in Hampshire co., Mass.; on the Ware river and the Boston and Albany and the Boston and Maine railroads; 21 miles n.e. of Springfield. It was incorporated in 1761; contains the villages of Ware and West Ware; and has high and graded schools, free public library, electric lights, national and savings banks, weekly newspaper, and manufactories of cotton and woolen goods, hosiery, boots and shoes, wrought stone, etc. Pop. '90, 7329.

WARE, a small market t. in Herts, 2½ m. n.e. of Hertford. Malting, for which there are several establishments, most of them engaged in supplying the London breweries, is the principal employment. There is a silk-mill here and two large paper-mills, and there is a trade in malt, grain and coal. In one of the inns of the town is still to be seen the famous bed of Ware, for a notice of which, see Bed. Pop. '81, 5276; '91, 5121.

WARE, Henry, d.d., 1764–1845; b. Mass.; graduated at Harvard in 1785. He was pastor of the First church in Hingham, Mass., 1787–1805, when he was called to the Hollis professorship of divinity at Harvard college, where he remained till his death. During his residence at Cambridge the Congregational churches were divided into the groups known as Unitarian and Evangelical. Dr. Ware, with Drs. Norton and Channing, was one of the leaders of the former. He carried on a controversy with Dr. Woods, whom he answered in *Letters addressed to Trinitarians and Calvinists* (1820). He also published *Evidences, etc., of Christianity* (1842).

WARE, Henry, d.d., 1794–1843; b. Mass.; son of Henry. He was graduated at Harvard in 1812; was for a time an instructor in Phillips Exeter academy, and in 1817 was settled over the Second church (Unitarian) in Boston. He was professor of pulpit eloquence and pastoral care in the Harvard divinity school, 1830–42. He was one of the editors of the *Christian Disciple*, afterward the *Christian Examiner*, a Unitarian newspaper. Among his works are *Hints on Extemporaneous Preaching* (1824); and *Life of the Saviour* (1832).

WARE, William, 1797–1852; b. Mass.; son of the elder Henry. He was educated at Harvard college and the Harvard divinity school; was settled over Unitarian churches in Brooklyn, Conn., Burlington, Vt., New York, and Waltham, Mass., and retired from the ministry on account of ill-health. His historical novels, *Zenobia*, originally published in the *Knickerbocker Magazine* for 1837, as *Letters from Palmyra; Aurelian* (1838); and *Julian* (1841), had considerable reputation. He was for some years editor of the *Christian Examiner*.

WAREHAM, an exceedingly ancient though small t. of Dorsetshire, stands between the rivers Piddle and Frome, 15 m. nearly due e. from Dorchester. It was a British town, and afterward a Roman station, and is surrounded by a British vallum or rampart of earth, which, although extremely ancient, is still about 30 ft. high, and is perfect on three sides. The chief trade is the export of potter's clay; there are also breweries, malt-houses, and brick-fields. The borough comprises the parishes of Holy Trinity, Lady Saint Mary, Saint Martin Arne, Bere Regis, Corfe Castle, and parts of the parishes of East Stoke and Morden. Pop. '91, 2141.

WAREHOUSEMAN, in law, any person receiving goods and merchandise for storage only. As a bailee he is held only to use ordinary care, as the contract is one of mutual benefit. But he may assume full responsibility by special agreement. The same party may be a warehouseman in certain relations and a common carrier in others. Thus, if a railroad makes a contract to store certain merchandise until a fixed day and then to transport it, it becomes a common carrier (and practically, an insurer) upon that day, whether the goods are then moved or not. The warehouseman's lien is for storage of the particular goods only and not for a balance of accounts. It has been held that his liability begins when the crane is attached to goods which are yet outside the storehouse.

WAREHOUSING SYSTEM is a plan for lessening the pressure of excise or customs duties by postponing payment of them until the goods they are laid on pass to the consumer, or, at all events, to the retail dealer. A merchant who might import a thousand pounds' worth of wine or tobacco, if he only paid duty on it by installments as it went out to the dealer, would be quite unable to import so much if he had to pay somewhere from one to five thousand pounds of duty on its arrival. The system of bonded warehouses was hence adopted. The taxable commodity thus came to be locked up in a government warehouse, and the duty to be paid on its removal, along with a proportional fee or rent for the custody of the article, or its accommodation in government premises. Bonding in this manner was part of the scheme of sir Robert Walpole, in 1733, generally known as the excise scheme, which was defeated from its unpopularity. The system was first authorized by an act of George III. in 1802. When the customs laws were from time to time consolidated, the warehousing act formed a portion of the consolidation. In the consolidation of 1846 there was a separate "act for the warehousing of goods." In the latest consolidation of 1853 the warehousing system is embodied in clauses 41 to 113 inclusive of the general "customs consolidation act" (16 and 17 Vict. c. 107). This process, by which the crown holds in custody the goods of private persons, has produced some curious effects on mercantile law and trading practices. When transactions have taken place about bonded goods, should they be injured or destroyed, it may come to be a question of nice adjustment who is to bear the loss, seeing there is not possession to show ownership; and still nicer questions sometimes arise as to whether such goods are or are not part of a bankrupt estate. There is a difficulty in securing money upon goods without transferring their absolute possession, as in the case of pledging or pawning. The warehousing system, however, by retaining the goods for the owner, whoever he may be, has created a complete system of paper money in the transference of the title-deeds, as they may be called, of such goods—the dock-warrants or other documents—the possession of which is equivalent to possession of the goods.

WARFIELD, Catharine Anne (Ware), 1816–77; b. Washington, Miss.; daughter of Nath. A. Ware, secretary Mississippi territory (an author and writer on political economy), granddaughter of Capt. Charles Percy, of the British navy; educated at Philadelphia; married Elisha Warfield of Lexington, Ky., in 1833, and removed to a farm near Louisville. With her sister, Mrs. Eleanor Lee (d. 1850), she published *The Wife of Leon, and other Poems* (1843), under the *nom de plume* of "Two Sisters of the West." She was sole author of *The Household of Bouverie* (1860), new ed. 1875); other romances following annually; among them *Hester Howard's Temptation* (1875).

WARHAM, John, 1590–1670; b. England; was a distinguished Puritan minister at Exeter; came to Massachusetts in 1630; was with the Plymouth church, and was co-pastor with John Maverick; was settled at Dorchester; the church removed to Windsor, Conn., and the following year Mr. Warham followed and joined them.

WARING, George E., b. N. Y., 1833; for a time agricultural engineer of Central park, New York. He was col. of the 4th Missouri cavalry during the late civil conflict. Among his works are: *Whip and Spur; A Farmer's Vacation; The Bride of the Rhine;* and *Tyrol and the Spirit of the Alps.* He is a sanitary engineer of wide reputation, and has published *Sanitary Drainage of Houses and Towns.* In 1895 he was appointed by Mayor Strong commissioner of street cleaning in New York, and during his three years' term of office managed the department with great efficiency.

WARLOCK (written also warluck, from A. S. *wärloga*, "a breaker of his word or agreement"), denotes a male witch ; a wizard ; or sprite. See Witchcraft.

WARM-BLOODED ANIMALS. Under this title are included those vertebrates which possess a four-chambered heart and spongy lungs; the heart and lungs being so arranged that the whole of the venous or impure blood is propelled over the large but closely-packed capillary area of the lungs, by successive contractions of a special ventricle, receiving it from a distinct auricle (these being called the right or pulmonary ventricle and auricle), while the blood thus purified by the action of the air in the lungs is conveyed to another auricle, and propelled over the whole system by a second distinct ventricle (these being known as the left or somatic auricle and ventricle). The only animals which exhibit these structural peculiarities are mammals and birds. In man and in the ox the mean temperature of the interior of the body is 100°; in the mouse it is 99°; while in the whale it is 103°. In birds it ranges, in different species, from 106° to 112°. The warm-blooded animals present, however, gradations of their heat-making power. In the hibernating animals there is commonly a loss of heat of from 10° to 20° during their winter-sleep; and in the bat the temperature falls to 40°. In the cold-blooded animals, the fishes, amphibians, and reptiles, the temperature of the blood rarely exceeds that of the surrounding medium. See Birds and Mammalia.

WARMING and VENTILATION. Warming.—A certain temperature, constant within narrow limits, is essential for the life of warm-blooded animals, and the heat by which this temperature is maintained is produced by the vital actions of the body itself. See Animal Heat, Temperature of the Body. In the case of man, however, at least in ordinary climates, and in the civilized condition, the heat of the body, if allowed freely to escape, would be dissipated faster than it is produced; and hence arises the necessity of clothing, houses, and other means of retarding its escape. To allow the body to continue depressed in temperature beyond the natural state, instead of hardening, infallibly weakens its vitality, and sows the seeds of disease; and that this error is committed on a vast scale, in Britain more especially, is apparent enough. The reports of the registrar-general show that exactly as the thermometer sinks, the rate of mortality rises and certain diseases of the most fatal kind become more prevalent; the vitality, in short, of the community decreases as the warmth of the atmosphere decreases. Could this be if the means taken to arrest the waste of heat from our bodies, or to supplement it, were not, for the majority of men and women, insufficient, or injudiciously managed? This is a matter of literally "vital" moment to one and all. The economy of heat is a primary element in the art of living in health and comfort; and "no knowledge of common things" that we can think of can surpass in importance a right understanding of the principles and facts on which that art rests.

Where fuel is scarce the resource against the cold of winter is thick clothing indoors as well as out. This is said to be the regular practice in China; and even in the south of Europe fires are dispensed with in weather when we should think them absolutely necessary, and additional wrappings are considered as appropriate while sitting in the house as in the open air. But wherever fuel can be had, it is always preferred to wear within doors much the same clothing in winter as in summer, and to keep the apartments nearly at summer temperature by artificial heat. It is this special branch of the subject, viz., the artificial warming of apartments, that we are at present to consider; and in doing so, we presume the reader to be acquainted with the more general facts regarding the generation of heat by combustion, and its diffusion, as stated in the articles Combustion, Flame, Fuel, Heat.

The great aim, it may be premised, in all plans of warming is, as it is expressed by Dr. Arnott, "*to obtain everywhere on earth at will, the temperature most congenial to the human constitution, and air as pure as blows on a hill-top.*" The obtaining of the desired temperature would be comparatively easy by itself; the difficulty lies in combining warmth with pure air. Warming and ventilation are thus in some degree antagonistic operations, and are therefore best treated in one article. The various plans of warming hitherto tried may be classed under the four heads of the open fire, stoves, gas, steam and hot-water.

The Open Fire.—The first application of artificial warmth consisted, most likely, in lighting a fire of dried sticks and leaves in a grove, a cave, or other natural shelter. When tents or wigwams came to be erected, the fire would be lighted on the middle of the floor, with perhaps a hole in the roof for the smoke to escape by. This primitive arrangement may still be seen in some of the cabins of Ireland and the Scottish highlands. The Romans warmed their apartments chiefly by portable stoves or chafing-dishes, without any regular exit for the smoke and fumes; and a brasier of charcoal is still the chief means of heating sitting-rooms in Spain and Italy, which are in general without chimneys. The chimney (q.v.) is a modern invention.

The open coal-fire glowing in a grate, which is the prevalent mode of warming dwelling-houses in Britain, has an air of cheerfulness and comfort, and a power of concentrating the whole family in one social circle, that make it almost an object of worship; but it is not without serious drawbacks, the most serious of which is the waste of fuel it occasions. About one-half of the heat produced by a common fire ascends with the smoke—the black part of the smoke itself being an unconsumed part of the fuel—while about a fourth of the heat which is radiated into the apartment is, in ordinary circumstances, carried into the chimney between the fire and the mantel-piece, and thus lost. It was calculated by Dr. Arnott that only about one-eighth part of the heat-producing power of the fuel used in common fires is realized, all the rest being dissipated into the surrounding atmosphere. A common fire gives also a partial kind of warmth, heating the side of the body next to it, but leaving the rest cold; and it produces draughts into our rooms which are anything but safe or agreeable. Notwithstanding these and other acknowledged evils, the open fire continues to hold its place, partly perhaps from prejudice, partly from real points of superiority over other methods as yet practiced; and the object of late has been not so much to do it away, as to improve it.

Grates.—One improvement consists in diminishing the quantity of metal in immediate contact with the fuel, and forming the back and sides of the grate of fire-bricks. The bricks act like clothing, and keep in the heat of the coals, thus rendering the combustion more complete, and the fire far hotter; while iron, being a good conductor, runs away with the heat as fast as it is generated, and passes it into the wall, making the coals that touch it dull and black. The same quantity of fuel, therefore, burned in a brick-lined grate, not only produces more heat, but throws a greater proportion of that heat out into the room, and less up the flue and through the wall, than when it is surrounded by a mass of iron; for radiation depends more upon the intensity of heat than upon its quantity.

Another point deserving attention is the shape given to the chimney-mouth, or recess above the grate. When the sides are square with the back none of the heat falling on them is given out again into the room. With a view, therefore, to throw out the heat better, the sides, or *covins*, as they are called, are inclined to the back at an angle of about 130°; and sometimes they are made curved and of polished metal, in order that they may reflect the heat without absorbing it. It is questionable if simple brick slabs, placed at the proper angle, do not throw out more heat than the most splendid polished metal plates; for though the bricks do not reflect the rays of the fire, they become heated themselves, and then radiate their heat into the room. Plates of rough metal absorb the heat that falls upon them as the brick does; but being good conductors, the heat passes through them into the wall, and thus they never become hot enough to radiate sensibly.

Much also depends upon the shape of the fire-box, or grate itself. To see the importance of this, it is necessary to attend carefully to the exact way in which an open fire heats a room. It does so almost entirely by the rays of heat that it throws out; and these rays do not warm the air directly; they pass through it like light through glass, just as the hottest rays of the sun pass through the upper atmosphere, leaving it cold enough to freeze mercury. It is only when the rays of the fire fall on the floor, furniture, and walls of the room that they gave out their heat; and it is by coming in contact with these solid heated bodies that the air is gradually warmed. We may thus see the necessity of having a fire lighted and burning brightly for a considerable time before the hour when the apartment is expected to be comfortable.

The law that radiant heat neither affects nor is affected by the surrounding air, also explains the fact that an apartment may feel very cold, though the air in it be at high summer heat. A church or other massive stone building in frosty weather may be filled with artificially-heated air and yet retain its chilling effect for many hours. The warmth of the living body is lost in two ways: the film of colder air that touches it receives part of its heat by conduction, and, rising up, makes room for another film to do the same; a moderately heated body in cooling is robbed of about half its heat in this way. The other half is given off in rays, which pass through the air, and impinge upon the objects around. These objects are radiating back heat in return; but their temperature being low, the return is small, and the warmer body is colder by the difference. Hence we are chilled by a cold wall or a cold window without touching it, and though the air between us and it may be at 70°.—To return to the shape of the grate:

The chief object is to present as large a surface as possible of glowing fire to the front. With this view, the grate is made long and deep, in proportion to its width from front to back. This principle, however, is carried too far in many grates. The stratum of fuel is too thin to burn perfectly, especially in the narrow angles at the sides, where the coals seldom get to a red heat, and are only warm enough to distil away in smoke. Such fires are constantly going out, and are further from being economical than a square box.

The practice recently come into vogue of placing grates almost on a level with the floor, is also a mistake. The floor and the lower part of the person receive no share of the radiant heat.

The chimney-throat, instead of a gulf drawing in a constant wide current of the warm air of the room, and causing draughts from windows and doors toward the fireplace, should just be sufficient to admit the burned gases and smoke that come directly

from the fire, and no more. See CHIMNEY. This is the object of the movable plate in what are called *register-grates.*

It would be endless to attempt to enumerate the various forms of grate constructed with more or less success on the above principles. We shall content ourselves with a notice of the recent invention of the late Dr. Arnott, to whom the subject of warming apartments is more indebted than to any individual since the days of count Rumford. It comes nearer to the idea of perfection in an open fire-place than any previous contrivance. Its peculiar advantages will be understood from the following description:

Arnott's Smokeless Grate.—ab, ef (fig. 1), represent the front bars of a grate in a chimney of the usual construction, *rswu.* The grate has no bottom, and below it is an iron box, open only at top, into which the charge of coal for the day—from 20 to 30 lbs.—is put. Any kind of coke or coal may be used. To light the fire the usual quantity of wood is laid on the surface of the fresh coal at *ef,* and a thickness of 3 or 4 in. of cinders or coked coal, left from the fire of the preceding day, is laid over all. "The wood being then lighted, very rapidly ignites the cinder above, and at the same time the pitchy vapor from the fresh coal below rises through the wood-flame and cinders, and becomes heated sufficiently itself to become flame and so to augment the blaze. When the cinder is once fairly ignited, all the bitumen rising through it afterward burns, and the fire remains smokeless."

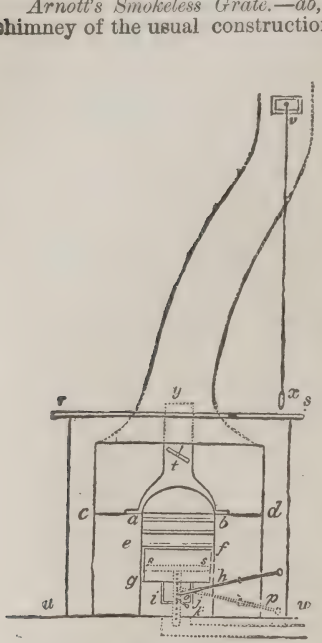

FIG. 1.

As there is no supply of air but through the bars in front, the box being close underneath, the fire must be gradually raised up as the combustion goes on; and this is effected by having a false bottom, *ss,* in the box, which can be moved like a piston by means of a rod. The rod has notches in it, and by means of the poker used as a lever can be raised up and then retained at any height by a ratchet-catch. When the piston comes level with the bottom bar of the grate, the coals may be replenished while the fire is burning by pushing in a flat shovel over the piston, so as to form a temporary bottom to the grate and support the fire, while the piston is allowed to descend to the bottom. The shovel is then raised up a little in front, or a part of the upper edge of the box is made to fold down, and fresh coals are shot into the box; on which the shovel is withdrawn and the combustion goes on as before.

"A remarkable and very valuable quality of this fire is its tenacity of life, so to speak, or its little tendency to be extinguished." Even after it sinks below the level of the box it does not go out, but continues to smolder slowly for a whole day or night, and is ready to burn up actively when the piston is raised.

Another peculiarity of the Arnott grate is the means taken to diminish the proportion of the heat usually carried up the chimney. Of the thick column of smoke that issues from a common chimney-can, only a small fraction is true smoke or burned air; the rest consists of the warmest air of the room, which becomes mixed with the true smoke in the large space usually left between the top of the fire and the throat of the chimney. "The whole of the air so contaminated, and which may be in volume twenty, fifty, or even a hundred times greater than that of the true smoke or burned air, is then all called smoke, and must all be allowed to ascend away from the room that none of the true smoke may remain. It is evident, then, that if a cover or hood of metal be placed over a fire, as represented by the letters *yab* in the diagram—or if, which is better, the space over the fire be equally contracted by brickwork, so as to prevent the diffusion of the true smoke or the entrance of pure air from around to mix with it, except just what is necessary to burn the inflammable gases which rise with the true smoke—there will be a great economy. This is done in the new fire-place with a saving of from one-third to one-half of the fuel required to maintain a desired temperature. In a room, the three dimensions of which are 15 ft., 13½ ft., and 12 ft., with two large windows, the coal burned to maintain a temperature of 65° in cold winter days has been 18 lbs. for 19 hours, or less than a pound per hour."—Arnott's *Warming and Ventilation.*

The hood is furnished with a throttle-valve or damper, *t,* having an external index showing its position, so as to give complete control over the current. The provision made for ventilation in this fire-place is considered further on.

Even in this, perhaps the most economical form of open fire yet contrived, there is still great waste of the heat actually produced by the combustion. To say nothing of what passes by conduction from the fire itself into the wall and is mostly lost, the quantity carried off in combination with the hot gases, though no more air is allowed to enter

than is necessary for complete combustion, is still great. It deserves being noticed that the proportion thus carried off is greatest in the case of fuel that burns with flame. Experiment shows that a fire of wood radiates one-quarter of its heat, the rest flying up; while the radiation from wood-charcoal is one-half of the whole heat produced. Every one has felt that a *blazing* fire has far less warming effect than a glowing one. Not that flame has not intense heat in it—more intense even than a glowing fire, but it gives it out only by contact and not by radiation. It thus appears that any mode of heating that depends upon direct radiation, as the open fireplace chiefly does, necessarily involves great waste of fuel. This can be avoided only by applying the heat on a different principle, which consists in first making the fire heat certain apparatus with considerable surface, which then by radiation and contact with the air of the apartment diffuses its heat throughout it. This is the principle of the other methods of warming, which we now proceed to describe. The consideration of methods that combine the two principles will come most conveniently last.

Warming by Stoves.—A *close stove* is simply an inclosure of metal, brick, or earthenware, which is heated by burning a fire within it, and then gives out its heat to the air by contact, and to surrounding objects by radiation. The simplest, and, so far as mere temperature is concerned, the most effective and economical of all warming arrangements, is what is called the Dutch stove; which is simply a hollow cylinder or other form of iron standing on the floor, close at top, and having bars near the bottom on which the fire rests. The door by which the coals are put in being kept shut, the air for combustion enters below the grate, and a pipe issuing from near the top carries the smoke into a flue in the wall. If this pipe is made long enough by giving it, if necessary, one or more bends, the heated gases from the fire may be made to give out nearly all their heat into the metal before they enter the wall; and thus the whole heat of the combustion remains in the room.

The great objection to this form of stove is that the metal is apt to become overheated, which not only gives rise to accidents, but has a hurtful effect upon the air. The exact nature of the change that highly heated metal produces upon air is not very well understood. It cannot be said to burn it, in the proper sense of the word, for none of its oxygen is abstracted, but it gives it a peculiar odor, which is both unpleasant and unwholesome. This is thought to arise in some measure at least from the hot iron burning the particles of dust that light on it, which particles consist of organic matter, such as wool, wood, etc.

Part at least of the unwholesomeness of air so heated arises from its excessive dryness; it parches and withers everything it touches, like the African simoom. It must not, however, be supposed that this is peculiar to air heated by contact with metal; *air suddenly heated is always unwholesomely dry.* This is an important point in regard to the subject of warming, and requires consideration. A cubic foot of air, say at 32°, can contain a certain quantity of moisture and no more; but if heated to 80°, it is capable of containing *five* times as much, and has thus become *thirsty*, and drinks up moisture from everything that contains any. The heating of air, therefore, does not dry it, in the sense of taking moisture from it, it only renders it greedier of more; and this is equally true whether it is heated by a stove or an open fire. The chief difference is that in the latter case the warming is more gradual, and no part of the air becomes very highly heated; while the air that touches a metal plate near redness is all at once rendered intensely thirsty, and, before its fierceness is tempered by thoroughly mixing with the rest of the atmosphere of the room, must be highly pernicious. But whenever the temperature within doors is much higher than without, the air is in a too thirsty state, and parches the skin and lungs, unless means be taken to supply the necessary moisture. *An evaporating pan or other contrivance is an essential part of warming apparatus;* it is specially necessary to attend to this during e. winds, which are generally too dry even at their natural temperature.

All improvements on this simple and rude form of stove aim at avoiding a high heat in the warming surface, and this chiefly by lining the fire-box with brick, and inclosing it in several casings, so as to enlarge the heated surface. In the kind of stove called a *cockle*, the fire is burned in a small furnace within the inner case, and the air is warmed by circulating between the inner and outer cases. When placed in the apartment or hall to be warmed, the outer casing has perforations about the top for the issue of the warm air. For heating churches and similar buildings, the stove is placed in a separate furnace-room, and the warm air is conveyed to the different parts of the building in pipes or flues, while fresh air is drawn to the stove through a channel or culvert leading from outside the building to the openings in the outer casing.

The stove invented by Dr. Arnott is upon the same principle of an extensive and moderately warm heating surface. Under a sense of professional honor, Dr. Arnott did not take out a patent for his stove; it was therefore made by many furnishing ironmongers in the metropolis and elsewhere, some of whom took out patents for what they considered as improvements upon it. No fewer than 12 patents were taken out in one year for modifications of this stove, *all of which Dr. Arnott considered to be upon false principles.* The consequence has been that many Arnott stoves, which had been introduced into houses, have been given up on account of the inconvenience felt from the species of heat which they generated. It is also, however, to be observed that the stove,

made even upon the most approved principles, requires certain adjuncts and conditions in order to operate healthfully and agreeably.

The accompanying figure represents the Arnott stove in the most improved form given to it by the inventor. We give the description in his own words: "The complete self-regulating stove may indeed be considered as a close stove, with an external case, and certain additions and modifications now to be described. The dotted lines and small letters mark the internal stove, and the entire lines, the external case or covering. The letters ABCD mark the external case, which prevents the intense heat of the inner stove, *abcd*, from damaging the air of the room. F is the regulating-valve, for admitting the air to feed the fire. It may be placed near the ash-pit door, or wherever more convenient. The letters *ff* mark the fire-brick lining of the fire-box or grate, which prevents such cooling of the ignited mass as might interfere with the steady combustion. H is a hopper, or receptacle with open mouth below, suspended above the fire like a bell, to hold a sufficient charge of coal for 24 hours or more, which coal always falls down of itself, as that below it in the fire-box is consumed. The hopper may at any time be refilled with coal from above, through the lid, *k*, of the hopper, and the other lid, K, of the outer case. These lids are rendered nearly air-tight by sand-joints; that is, by their outer edges or circumference being turned down, and made to dip into grooves filled with sand, as at *e*, *e*. The burned air or smoke from the fire, M, rises up in the space between the hopper and the inner stove-case, to pass away by the internal flue, *x*, into the other flue, X, of the outer case. L is the ash-pit under the fire-bars. G is the ash-pit door, which must be carefully fitted to shut in an air-tight manner, by grinding its face or otherwise. M is the coal intensely ignited below where the fresh air maintains combustion, but colder gradually as it is further up. Only the coal in the fire-grate below, where the fresh air has access to it through the fire-bars, can be in a state of active combustion." The self-regulating valve above mentioned is an ingenious contrivance by which the passage for the air is rendered narrower according to the force of the draught. Dr. Arnott describes various other plans of effecting the self-regulation of the combustion.

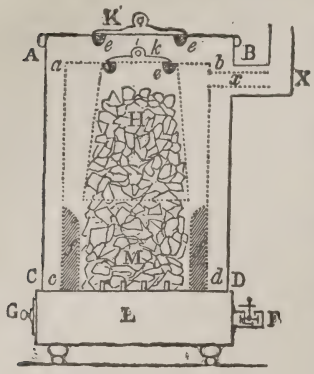

Fig. 2.

A drawer inserted into the heated chamber of the stove would serve for cooking meat, and a pot for boiling might be placed upon the fire box; it is, therefore, as the inventor remarks, peculiarly the *poor man's* stove. Or, by making the space between the two casings water-tight, a *water-stove* is produced, which, besides securing a regulated heat, offers many other conveniences.

In Russia, many parts of Germany, and other northern countries of Europe, the stoves are usually built of brick, covered with porcelain. They are of the size of a large and very high chest of drawers, and usually stand in a corner of the room. The fire is burned in a furnace near the bottom, and the heated smoke is made repeatedly to traverse the structure from side to side, along a winding passage, before it reaches the top, where a pipe conveys it, now comparatively cold, into a flue in the wall. The heated mass of brick continues to warm the room long after the fuel is burned. It is generally sufficient to warm the stove once a day. The same quantity of wood burned in an open grate would be consumed in an hour, and would hardly be felt.

Open-fire Stoves.—As a specimen of the numerous plans for combining the advantages of the stove and the open fire, we may take Sylvester's stove or grate, which is thus described in Ronalds and Richardson's *Technology:* "The fuel is placed upon a grate, the bars of which are even with the floor of the room. The sides and top of these stoves are constructed of double casings of iron, and in the sides a series of vertical plates, parallel with the front facing, are included in the interior, which collect, by conduction, a great portion of the heat generated from the fire—the mass of metal of which these are composed being so proportioned to the fuel consumed that the whole can never rise above the temperature of 212° Fahr. under any circumstances. The sides and top of the stove are thus converted into a hot chamber, offering an extensive surface of heated metal; at the bottom, by an opening in the ornamental part, the air is allowed to enter, and rises as it becomes warmed, traversing in its ascent the different compartments formed by the hot parallel plates, and is allowed to escape at the top by some similar opening into the room." The Sylvester stove can either be placed in an ordinary chimney recess or be made to stand ornamentally forward into the room. The feeding-draught may be either taken directly from the apartment or brought by flues from the outside of the building.

The idea of having an air-chamber behind and around the fire-place, from which warm air would issue into the room, thus saving part at least of the vast amount of heat that is lost by passing through the wall, is not new, having been put in practice by the

cardinal Polignac in the beginning of last century. But the way to carry the principle out to the full would be to have the open fire-place in a pier of masonry standing isolated from the wall, like a German porcelain stove. A very small fire would keep the whole mass mildly heated. The pier could receive any shape, so as to give it architectural effect; and it might either terminate in the room—the smoke, after parting with most of its heat, being conducted by a pipe into the wall—or it might be continued into the story above, where its heat would still be sufficient to warm a bedroom. An Arnott smokeless grate, set in the pedestal of an ornamental column, which might either stand in front of the wall or in a niche in its depth, might be made the *beau-ideal* of comfort, economy, and elegance.

Warming by Gas.—A prejudice arose against gas as a medium of heat, from the first attempts to employ it being made in an unskillful way. But when care is taken to carry off the products of combustion by a pipe, and to prevent overheating, gas-stoves will be found economical and pleasant, and capable of being used in situations where a common stove is inadmissible.

In stoves gas should always be burned with the Bunsen burner, which is generally employed by chemists when they make use of gas for heating purposes. It consists of a small brass cylinder, or chimney, set over the gas-jet, like the glass of an argand lamp, with openings near the bottom to allow air to enter. The gas being admitted into this before lighting, mixes with the air, and when lighted at the top, which is usually covered with wire-gauze or perforated metal, burns with a pale-blue flame. The most complete combustion and the greatest heat are obtained in this way. Smoke, properly so called, there is none. Still, it must not be forgot that there is burned air—a cubic foot of carbonic acid, besides a quantity of watery vapor, for every cubic foot of gas used; and, therefore, even with the Bunsen burner, these gaseous products should, wherever it is possible, be conducted away.

A pleasant and very serviceable gas-stove might be constructed by making the casing double, to contain water. It has been ascertained that a gallon of water may be brought to the boiling point in 20 minutes by burning 4 cubic ft. of gas, which, at 4s. 6d. per 1000 ft., costs less than a farthing. The cost of doing the same by a newly-lighted coal-fire is more than threefold.

Steam and Hot Water.—The immediate warming agent in these two methods is the same as in Arnott's and other low-temperature stoves—viz., an extensive metallic surface moderately heated; but instead of heating these surfaces by direct contact with the fire, the heat is first communicated to water or steam, and thence to the metal of a system of pipes. This affords great facility in distributing the heat at will over all parts of a building; and these methods are peculiarly adapted to factories, workshops, and other large establishments. Other advantages are—freedom from dust, and from all risk of overheating and ignition.

Steam.—Steam-warming is generally adopted in establishments where steam-power is used, as the same boiler and furnace serve both purposes. When steam enters a cold vessel it is condensed into water, and at the same time gives out its latent heat till the vessel is raised to 212°, when the condensation ceases. The condensing vessel is usually a cast-iron pipe placed round the wall of the apartment near the floor. In admitting fresh air into the room it may be made to pass over this pipe, and thus be warmed. The steam is conducted from the boiler by a smaller tube, which may be covered with list or other material, to prevent all condensation by the way; and the admission of the steam is regulated by a cock within the apartment, means being provided for allowing the air to escape. Where a pipe cannot be laid round the room, a coil of pipe may be formed, or the steam may be admitted into a large vessel or into a hollow statue, forming a steam-stove. Allowance must be made for the expansion of the tubes by heat; and they are so arranged that the condensed water is conveyed back to the boiler.

There can be no proper comparison between this plan of heating and that of common fire-places. Coal-fires cannot warm the air in large workshops; the heat is confined to their own immediate neighborhood; hence the workmen are often obliged to draw near the grate to warm themselves. According to the plan here adopted every part of the house is equally heated, and the whole of the workmen are as comfortable during the hardest frosts as if they were working in a pleasant summer day. It is difficult to estimate the expense of supplying the heat, seeing that the steam happens to be drawn from a boiler which is always in operation for other purposes. Excellent, however, as the process is, it is for many reasons unsuited to private dwelling-houses.

In calculating how much surface of steam-pipe will be sufficient to warm a room, it is customary to allow about 1 foot square for every 6 ft. of single glass window, of usual thickness; as much for every 120 ft. of wall, roof, and ceiling, of ordinary material and thickness; and as much for every 6 cubic ft. of hot air escaping per minute as ventilation, and replaced by cold air.

Hot Water.—Hot-water apparatus was applied as early as 1777 by M. Bonnemain, in Paris, to warm the hot-houses at the Jardin des Plantes, as well as for the artificial hatching of chickens. It was first introduced into England by the Marquis de Chabannes in 1816, and is now used in many large buildings. It is more economical than steam, except where a steam-boiler is required for machinery; and from this and other

advantages it is generally preferred to steam-apparatus. One of these advantages is that the heat begins to be distributed, in some degree, as soon as the fire is lighted, while with steam-apparatus the whole of the water must be at boiling-heat before any steam enters the pipes.

There are two kinds of hot-water apparatus—high-pressure and low pressure. In the first the water is confined, and can be heated to any degree; in the other it is open to the air, and cannot be heated above 212°. Fig. 3 will explain the way in which water is made to carry the heat of a furnace to any part of a building by the low-pressure method. *a* is a boiler, from the top of which a tube issues, and after circulating through the building, re-enters near the bottom. At the top of the circuit there is a funnel, or a small cistern, *c*, by which the tubes and boiler may be kept full. When the fire is lighted at the bottom of the boiler, the heated portion of water, being lighter than the rest, rises toward the top through the tube *bb*, while the colder water from *dd* flows in to take its place. The tube is made to traverse the apartments to be warmed, where it gives out its heat to the air; the returning portion of the pipe is thus always colder and therefore heavier than the other, so that the circulation is constantly kept up. The warming surface is increased, wherever it is necessary, by coiling the pipe, or by making expansions upon it of various forms, so as to constitute water-stoves.

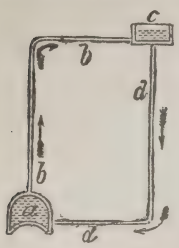

Fig. 3.

To avoid the necessity of so large a surface, and such a mass of water as is required at the low-temperature the water attains in the pipes of this kind of apparatus, Mr. Perkins introduced the high-pressure system. In this the pipe is made comparatively small, but very strong, and is formed into an endless circuit cut off from the atmosphere. The water is heated by making a number of coils of the pipe itself pass through the furnace; and as the whole circuit forms a shut vessel, as it were, the temperature may be raised to 300° and upward, according to the strength of the pipes. This high temperature causes a rapid circulation. In filling the tube with water care is taken to expel all the air; and at the top of the system there is an expansion of the tube, equal to 15 or 20 per cent of the capacity of the whole, which is left empty both of water and air, to allow for the expansion of the water when heated. The arrangement of the pipe may be various: the plan generally followed is to place a considerable coil of it within a pedestal or bunker, with open trellis-work in front, in a convenient part of the room. It may also be made to wind round the room, behind the skirting-board, which, being perforated with holes, will allow of the entrance of the warmed air.

Electricity.—The method of heating by electricity, although not as yet very generally adopted, except in special cases, has attracted great attention during the last few years, in which time it has been largely experimented upon and reduced to a thoroughly practical system. Electric heaters are simply a number of wires of high electrical resistance which become heated on the passage of a current through them. These are incased in fire clay, asbestos, or other similar materials, which retain their heat for some time. (See Electric Heating.) Heaters of this character are very generally used on electric railway cars, and their use is gradually extending in other directions.

Conservation of Warmth.—The art of warming embraces not only the production and distribution of heat, but the construction of apartments with a view to prevent its escape. The way to effect this—setting aside in the meantime the necessity of renewing the air—is, in the first place, to make the walls, floor, windows, doors, etc., as impervious to air as possible, to prevent the heat from being carried off by currents; and in the next place, to make them bad conductors of heat. For this last purpose, the walls ought to be sufficiently thick, and, if possible, built of non-conducting materials. Solid iron would make a cold wall; wood, a warm one; and in this respect brick or porous stone is preferable to hard stone. But the chief element in a warm wall is that it be *double*, which every wall in effect is when it is lined by a coating of plaster, kept apart from the wall itself by the laths. The plate of confined air between the two is the most effectual barrier to the passage of heat outward that could be contrived. By making iron walls double or cellular, with a lining of plaster, they might be rendered as warm as wished. Windows are a great source of cold, not merely by admitting cold air, but by allowing the heat to pass by conduction through the thin glass. The air of the room that touches the window is robbed of its warmth, and is constantly descending in a cold stream toward the floor. There is thus a cold influence felt from a window, however close it is. This is partly arrested by window-blinds, shutters, and curtains, which check the flow of the air, and retard its carrrying power. But a far more effectual plan is to have double windows: either two frames, or double panes in the same frame. The loss of heat by a double window is said to be only one-fourth of that by a single. Double windows are considered essential in countries where the winters are rigorous.

By carrying those principles far enough, we might succeed in well-nigh imprisoning the heat, and thus produce a house of ideal perfection, so far as mere temperature is concerned. But for the habitation of living beings another condition, seemingly antagonistic to the former, is no less requisite—"air as free as that on a mountain-top."

In general practice the two hostile conditions are not so much sought to be reconciled as compromised; and then, as usual, neither object is well attained. Circulation of air is got accidentally, through the imperfections of structure in our rooms—through the chinks and bad fittings of the windows, doors, floors, and the uneconomical fashion of our fire-places. Were houses much better constructed than they are, the inmates would in many cases be suffocated outright, as they often partially are with the degree of perfection we have already attained. Neither the airing of our houses, nor the art of building them solid and warm, can advance to perfection until the former be no longer left to chance, but be in every case secured by special apparatus capable of direct control. We now proceed to consider how this is sought to be attained; confining ourselves still to the leading principles, and only noticing a few of the specific plans that have been put in practice.

Ventilation.—The necessity of constantly renewing the air wherever living beings are breathing, arises chiefly from the effects produced upon air in the lungs (see Respiration). The average quantity of carbonic acid in expired air or breath is found to be 4.3 per cent by measure. Now this gas, when taken into the lungs, is a poison, and tends to arrest the vital processes. Like other poisons, however, it can be rendered harmless by *dilution*. The small proportion naturally existing in the atmosphere is perfectly innocuous, and may be considerably increased without sensible effect. But it is decidedly prejudicial to breathe for a long time air containing 1 measure in 100 of carbonic acid; and it is considered desirable that the proportion should never exceed 1 in 500. We may assume, then, what is near the truth, that 20 cubic ft. of air pass through the lungs of a man in an hour. To reduce the poison of this to 1 per cent, at which point it is barely respirable, it requires to mingle with as much fresh air as will make a mixture of nearly 100 cubic feet; and to make the dilution at all safe, it must be carried five times as far. In other words, the respiration of one human being vitiates hourly about 500 cubic ft. of air.

In addition to carbonic acid, expired air contains an undue amount of watery vapor. Minute quantities of animal matters are also exhaled with the breath, which in close, ill-ventilated apartments form a clammy deposit on the furniture and walls, and, by putrefying, become organic poisons.

A further necessity for the constant renewal of fresh air arises wherever lights are burned. The deteriorated air of a fire goes off by the flue, but lights are generally burned where the product must mingle with the atmosphere of the apartment. Now, a pound of oil in burning consumes the oxygen of 13 ft. of air, and produces a large amount of water in vapor, and also of carbonic acid. Every cubic foot of gas consumes the oxygen of 10 ft. of air, and forms at least 1 foot of carbonic acid, besides watery vapor, sometimes mixed with sulphurous fumes.

To counteract these various sources of pollution, and keep the air sufficiently fresh and wholesome, in rooms where many persons are breathing, it is found in practice that on an average about 20 cubic ft. of fresh air per minute for each individual must be supplied.

Ventilation consists of two operations—the removal of the foul air, and the introduction of fresh. Though neither operation can go on without the other going on at the same time, it is convenient to consider the two separately.

The agents employed in removing the air from apartments are chiefly two: that by which nature effects the ventilation of the earth on a grand scale, viz., the draught of ascending currents produced by difference of temperature; and mechanical force, such as pumping. The former is the more common, and is the only one applicable to private houses.

The column of air in the chimney of a lighted fire-place being expanded and comparatively light, exerts less than the prevailing pressure on the air immediately under and about its base. The air, therefore, below and around it pushes it up, and flows in to take its place; the velocity of the movement being in proportion to the height of the chimney and the degree of heat. Thus, although it is often convenient to speak of the air being *drawn* or *sucked* into the chimney, the force does not lie in the chimney, but in the greater pressure of the air behind.

Wherever, then, there is a heated chimney, there is a means of removing the foul air. And in rooms moderately lofty and spacious, with windows and other fittings not closer than usual, and a chimney mouth of the usual width, there is little risk, when there are only a few inmates, of any serious vitiation of the air. The heated breath that ascends to the ceiling has time to diffuse itself gradually, and be drawn in a diluted state into the currents that are setting from all quarters toward the chimney. These currents, however, are one great objection to this mode of ventilation, as they consist in great part of cold air that has just entered by the doors and windows, and are strongest where the inmates sit to enjoy the fire.

The ascent of foul air to the top of the room dictates its exit in that direction, rather than low down at the mouth of the chimney. It is conceived by some that the carbonic acid of the breath, from its greater weight, must be chiefly at the bottom of the room; but this is a mistake. The heated breath ascends instantly, because it is, as a whole, lighter than the air around it; and the carbonic acid in it does not tend to separate from it and fall down by its superior weight, but, by the law of the diffusion of gases, seeks

to spread itself equally all over the room, and would do so though it were lying at first on the floor. It is on the principle of the foul air ascending at first to the top of a room, that Dr. Arnott's ventilating-valve is contrived. The valve may be used to supplement the open-fire draught in small and crowded apartments, and is essential where the fire is burned in a close stove or in the smokeless grate. The valve is represented at *v*, fig. 1. An aperture is cut in the wall over the chimney, as near to the ceiling of the apartment as may be convenient. In this is suspended a valve, capable of opening inward to the chimney, but not in the other direction, by which means a return of smoke is prevented. The valve is so balanced on its center of motion, that it settles in the closed position, but is easily opened. A flap of 36 sq.in. is sufficient, where there is good chimney-draught, for a full-sized room with company. This simple apparatus may be painted or otherwise made ornamental. It operates by virtue of the draught in the chimney. Whenever that is active from the presence of a fire, the valve is seen to open inward, and a stream of air from the top of the apartment passes through into the chimney, and is carried off. The operation is precisely equivalent to the stream of air always passing into a chimney between the fire and the mantel-piece, but has the great superiority of draining off the most impure air in the room. A wire descends to a screw or peg fixed in the wall, by which the opening of the valve may be limited or altogether prevented. This is a far more efficient plan of ventilation than an open window, or an opening in the wall near the roof, leading merely to the outer air; where there is an open fire in the room, such openings rather admit a rush of cold air than let out the foul.

There is generally more or less draught in a chimney, even without a fire, from the air within being slightly warmer than that without; and this action might be strengthened by burning a jet of gas within the ventilating aperture at *v*. Where a house is to be built new, some recommend having special ventilating-flues in the walls, separate from but close to the fire-flues, so that the air may be heated, and an ascending current produced. In weather when fires are not required, the draught can be maintained by gas-jets at the entrances to the vents. This plan of causing a draught by gas is applicable to churches and apartments without fire-places.

Where a fire is burned for the express purpose of producing a current of air, it is called ventilation by *fire-draught*. The plan has been exemplified with success in mines, where a fire being lighted at the bottom of a shaft, air is drawn off in all directions around, and sent up the shaft; to replace which, fresh air is constantly pouring down other shafts.

Many of our large buildings are ventilated by fire-draught. A school or church may be ventilated by having the flooring perforated with holes, through which air, warmed by hot-water pipes, passes to the interior. The ceiling is perforated, leading to a chamber which communicates with a vertical flue which leads to the fireplace of the warming-apparatus, situated at the foot of a flue. As the only air which reaches this must pass from the vertical flue, a constant current is maintained therein, and also through the apertures in the ceiling. Dr. Reid exemplified this method, first in his own class-room in Edinburgh, and afterward in various public buildings, among others, in the temporary house of commons, erected after the burning of the old house in 1834. The plan was attended with some inconveniences—in fact, no plan can meet every contingency—but, notwithstanding the storm of hostile criticism that was raised at the time, Prof. Tomlinson (*Treatise on Warming and Ventilation*, 1864) gives it as his opinion that "in the case of the temporary house of commons, where all the arrangements were left in his own hands, he succeeded in the proposed object of removing the vitiated air, and keeping up a constant supply of warm or of cool air to fill its place." The arrangements for warming and ventilating the English house of commons are a modification of Dr. Reid's plan.

In other cases, as at the prison in Millbank, warm air is admitted at the ceiling, and carried off by the draught of a chimney in connection with the sides or lower part of the rooms.

In these last-mentioned instances, the apparatus provides as well for the admission as for the removal of air. In ordinary dwellings no special provision is in general made as to admission. It is, in fact, not absolutely necessary; for the removal of a portion of the air of a room never fails to secure the entrance of a fresh supply somewhere. Whenever the chimney-draught or other means removes a little of the pressure inside the room, the pressure without forces air through every opening and chink; and even, were there no actual openings, would force it through the porous substance of the structure—such as mortar, and even wood itself. But this irregular source of supply has various inconveniences. It often requires more force to strain the air in this manner than the draught is possessed of, and then the chimney smokes; it is smoke produced by this cause that is curable by opening the door or window. Another objection is that impure air is often thus drawn into rooms from the lower parts of the building and from drains about the foundation. For these and other reasons there ought, in all cases, to be a free and legitimate entrance provided for fresh air, so as to give a control over it; and this entrance should be independent of the windows. It is a much disputed point whereabout in a room the air should be made to enter—some advocating openings for it near the floor, others near the ceiling; and it must be confessed that neither method has yet been rendered unobjectionable. One essential thing is to prevent the air from rushing

in with a strong current, by passing it through minute holes spread over a large space. A tube, for instance, leads from the outer air to a channel behind the skirting, or behind the cornice, and the air is allowed to issue into the room through minute holes, or through a long, narrow, and concealed opening covered with perforated zinc or wire gauze. The passage or tube leading from outside the wall can be more or less closed by a valve regulated from the inside.

But the great difficulty lies in the coldness of the air directly introduced from the outside, whether by the doors and windows, or through channels in the walls, and all such plans of ventilation must be considered as imperfect makeshifts. The fresh air ought in every case to be warmed before being admitted, or, at least, before being allowed to circulate in a sitting-room. In the smokeless grate (fig. 1) the air is led directly from the outer atmosphere into a channel underneath the hearth, and escaping below the fender and about the fire, is warmed before spreading through the apartment. With stoves and heated pipes, the air should enter about the heated surface; in stoves on the cockle principle, the fresh air, as it enters, is made to pass between the casings of the stove. With an open fire a very feasible plan is to make the fresh-air channel pass behind the fire-place, and allow the warmed air to escape from concealed openings about the chimney-piece and jambs, or from behind the skirting. In Condy's ventilating-grate, the fire-box is constructed of hollow pieces of fire-brick communicating with the external atmosphere and with the room.

For a house with fire-places of the usual construction, perhaps the simplest and most effective expedient is to admit the fresh air into the entrance-hall, and there warm it by means of a low-temperature stove or by hot-water pipes: its passage into the several rooms can then be provided for by regular channels, behind the skirting or otherwise. In America perforations are frequently made in certain parts of the doors, before which silk curtains are disposed, so as to temper the currents. It is almost unaccountable that in this country the plan of warming the lobby and staircase is so seldom resorted to. To say nothing of the comfort thus diffused through the whole house, and the benefit in point of health, especially to weakly constitutions, the economy of the arrangement is beyond dispute. In the sitting-rooms, not more than one-half the usual quantity of fuel requires to be burned in the open fires; and in the bedrooms, as a rule, fires are rendered altogether unnecessary in the coldest weather. It ought to be observed that when air is admitted by a regular and free channel, comparatively little is strained in by the windows and other byways.

Ventilation by Fans and Pumps.—The fan-wheel has been for many years used in factories, to which it is particularly applicable, from the readiness with which it can be kept in motion by the engine. It is essentially the same as the barn-fanners; the air is drawn in at the center of the wheel, and flies off at the circumference by centrifugal force. The fan is placed at the top of a flue, into which branches from all parts of the establishment proceed; and when it is set in motion, it draws off the air from every apartment communicating with it. Dr. Arnott observed that in the fan-wheel as well as in the air-pump or bellows invented by Dr. Hales, a great deal of power was wasted by "wire-drawing" the air—that is, making it squirt through small valves or other narrow openings. To obviate this, he invented a ventilating-pump, which supplied a hospital with fresh air, requiring no other motive power than the descent of the water used in the establishment from a high reservoir to the lower parts of the building. It is described in his work on *Warming and Ventilation.*

Transference of heat from the used air to the fresh.—This is the kind of economy which is put in practice in the respirator (q.v.) and in the caloric engine (q.v.). Whatever difficulties—or impossibilities, as some maintain—there may be in the way of turning this transferred heat into a fresh source of power, nothing seems simpler, in theory at least, than to economize heat in this manner for the warming of dwellings and similar purposes. The idea originated with Dr. Arnott, many years ago, who thus illustrates it in the case of water: Suppose a vessel of boiling water, with a thin metallic tube issuing from the bottom, and having a stop-cock at its extremity; and a similar vessel of water at freezing, the tube of which is larger, and envelopes the other. When both are flowing simultaneously, the hot water, if the tube is long enough, will have lost all its excess of heat before getting to the end of the tube, while the counter-current will have gained all that the other lost. In an experiment with tubes 6 ft. long, the boiling water from the first vessel issued from the pipe at 34°, and the freezing water from the second vessel issued from the pipe at 210°. It is clear that if the first vessel were a bath, the warm water in it, after being used, might in flowing out be made to heat the cold water from a reservoir, flowing into another bath below. We are not aware that the principle has ever been acted upon; but the possible economy of heat is obvious, and it only requires mechanical ingenuity to realize it.

It will at once strike the reader how desirable it would be to do the same with the impure heated air which we are obliged to eject from our dwellings. Where the ventilation depends upon the draught of a common chimney, it would seem impossible to bring the entering air in contact with that which is escaping; but where the mechanical force of a pump or a fan is employed, nothing seems simpler than to make the two currents run counter to one another for a certain distance in close contact through a system of tubes. The smoke even, which, with the most economical arrangements, still issues

from the flues at a temperature considerably above that of the building, might be drawn into the current along with the foul air of the apartments, and the whole reduced nearly to the temperature of the atmosphere before being allowed to escape. Of course there must be loss in the transference; but a large percentage would be saved, and the consumption of fuel would be reduced by that amount. Were this "double-current ventilation" applied to churches, ball-rooms, theaters, etc., where thousands of persons are assembled, Dr. Arnott believed that "no other heating apparatus would be required but the lungs of the company."

Notwithstanding all the improvements recently effected, it is beyond doubt that this important branch of the art of living is still in a very rude and imperfect condition. A writer in the *Quarterly Review* for April, 1866, in a very suggestive article on *Coal and Smoke*, points to the radical error of the existing system, when he remarks that "in a household fire heat is, as it were, manufactured on a very small scale; and experience has proved that the cost of production of an article has always been inversely proportionate to the scale of its manufacture." He accordingly suggests that "it seems practicable, in a great measure, to supersede domestic fires, and to lay on heat (heated air), or the means of generating heat (low-priced gaseous fuel), to our houses pretty much as we now lay on gas." The abatement of the smoke nuisance, and systematic and thorough ventilation, ought to be effected on a similar joint-plan, "by connecting the chimneys of all the houses with underground culverts, provided at intervals with high shafts, in which, if necessary, the draught upward might be increased by furnaces. We have long been familiar with extensive manufactories, covering large areas, in which are very numerous fires, all in communication with a single lofty chimney. With such an arrangement, no visible smoke should be produced, and with due attention a smoky chimney should be impossible." Regarding the subject in its aspect as to health, it may be assumed that no system of heating is advisable which does not provide for a constant renewal of the air in the locality warmed. All heating apparatus depends upon the transference of heat from the fire to the various parts of the building which it is intended to warm, and this transfer may be effected by radiation, by conduction, or by convection. Radiant heat is emitted and absorbed in an accelerating ratio in proportion as the difference of temperature between the radiant and the recipient increases; and, with the same difference of temperature between the recipient and the radiant, the effect of the radiant will be greater according to the increased temperature of the recipient. In other words, the ratio of the emission of heat increases with the temperature. It is thus easier to effect the warming of a given space by means of a highly-heated surface than by a surface emitting a lower temperature. An open fire acts by radiation; it warms the air in a room by first warming the walls, floor, ceiling, and articles in the room, and these in their turn warm the air. Therefore, in a room with an open fire the air of the room is, as a rule, less heated than the walls. In this case the warming of the air depends on the capacity of the surfaces to absorb or emit heat; except that the heat received by the wall may be divided into two parts, one heating the air in contact with the wall, and the other passing through the wall to the outer surfaces, where it is finally dissipated and wasted. Fire-places are sometimes constructed to assist the warming of the air of a room. For instance, in Sylvester's grate, iron bars, of which one end terminates under the fire, are laid so as to form a projecting radiating hearth. The ventilating fire-place warms the fresh air before its admission into the room by means of gills cast on the back of the grate. In a close stove, heated to a moderate temperature, the heat as it passes from the fire warms the surface of the materials which inclose and are in contact with the fire and the heated gases. The materials next transfer the heat to the outer surface in contact with the air, and the air is warmed by the agency of this outer surface. If heated to a high temperature a stove gives out radiant heat, which passes through the air to warm the objects on which the rays impinge. With hot-water pipes, the heat from the water heats the inner surface of the pipe, and this surface transfers its heat to the outer surface through the material of the pipes. The rate at which the heat can pass from the inner to the outer surface, and be thus utilized instead of passing away straight into the chimney, depends on the heat evolved by the fire, on the extent of surfaces exposed to the heat and their capacity to absorb and emit heat, and on the quality of the material between the inner and outer surfaces as a good or bad conductor of heat. This passage of heat through a body by conduction varies directly with the quality of material, and with the difference between the temperature of the inner surface exposed to the heat and the outer surface exposed to a cooling influence, and inversely as the thickness between the surfaces. Other things being equal, copper is a better material than iron for conveying the heat from the fire to water or air; and coverings of brick-work, wood, or woolen fabrics are better adapted than iron for retaining the heat. The property which appears more than any other to make materials good non-conductors of heat is their porosity to air, and the retention of the air in their pores.

Furnaces are largely used for heating. A pipe conveys the air from the outside of the building to the furnace; it is there heated and carried by distributing flues to the various rooms. From leakage or bad joints, carbonic oxide and sulphur gases often escape, and mingling with the heated air, are conveyed to the rooms. Care should be taken that the air brought to the furnace be not mixed with the stale air of the cellar. The opening of the air flue should be where there are no sources of contamination.

Great care should be taken in the construction of the furnace, and in its management; the water basin needs to be frequently replenished, to prevent the disagreeable dryness of the hot air. A system of heating from a central station, by steam or hot water, has recently been introduced in some cities. One of the central stations of such a system in New York has 64 boilers; from these the steam is discharged into vertical pipes or separators; it then passes into the street mains, which are from 10 to 24 in. in diam., and covered with mineral wool to prevent loss of heat; by the side of these is laid a return pipe, which carries the condensed water back to the boilers. Metres are employed, controlling and measuring the amount of steam used. Buildings along the line of the mains are furnished with steam for manufacturing or heating purposes. The system, though so recent as to be still in the stage of experiment, seems growing in public favor. See SANITARY SCIENCE.

WARMINSTER, a small ancient t. of Wiltshire, on the w. border of Salisbury plain, and 19 m. n.w. of Salisbury. The parish church dates from the reign of Henry III.; and the interesting edifices in the town and neighborhood are numerous. An important corn-market is held every week. Pop. '71, 5786; '81, 5460. '91, 5562.

WARNER, CHARLES DUDLEY, American author, was born at Plainfield, Hampshire co., Mass., Sept. 12, 1829; graduated at Hamilton College in 1851, and after spending a short time in surveying on the Missouri frontier, returned to the East in 1854, studied law in New York, and was admitted to the bar in Philadelphia in 1856. He practised in Chicago until 1860, when he removed to Hartford, Conn., to become assistant editor and afterwards editor-in-chief of the *Hartford Press*. In 1867 he became assistant editor of the *Hartford Courant*, with which he is still connected. In 1886 he took charge of that department of Harper's Magazine called the "Editor's Drawer." He has several times visited Europe and the East as correspondent for American newspapers, and has traveled extensively through the United States, contributing papers descriptive of social life and scenery to *Harper's Magazine*. He received the degree of A.M. from Yale in 1882, and from Dartmouth in 1884. He edited the *American Men of Letters* series, and has published *My Summer in a Garden* (1871) and *Back-Log Studies* (1872); *Saunterings* (1872); *Baddeck and That Sort of Thing* (1874); *In the Levant* (1876); *Mummies and Moslems* (1876); *Being a Boy* (1877); *A Roundabout Journey* (1883); *Their Pilgrimage* (1886); *On Horseback* (1888); *Studies in the South and West* (1889); *Our Italy* (1891); also the biographies, *Captain John Smith* (1881) and *Washington Irving* (1881); *A Little Journey in the World* (1890); and, in collaboration with Mark Twain, the novel, *The Gilded Age* (1873). In 1896–7 he edited the *Library of the World's Best Literature*.

WARNER, OLIN LEVI, b. Suffield, Ct., 1844. He studied sculpture in Paris at l'École des Beaux-Arts under Jouffroy, and in the studio of Carpeaux. Among his works are a bust of Rutherford B. Hayes, a medallion of Edwin Forrest, the statuettes "May" and "Night," and the heroic statues of Gov. Buckingham, Wm. L. Garrison, and Gen. Devens. At the time of his death (1896) he was engaged upon reliefs for the doors of the congressional library at Washington.

WARNER, SETH, 1743–84; b. Conn.; a leader of the "Green Mountain boys" in the disputes between New York and Vermont, where he had settled in 1765. At the capture of Ticonderoga and Crown Point in 1775 by Ethan Allen, he was second in command. As col. of Vermont forces, he participated in Montgomery's expedition to Canada; and he was commander at the action at Hubbardton in 1777. He was also at the battle of Bennington, and remained in the service till 1782, when ill health forced him to retire.

WARNER, SUSAN, b. New York, 1819; daughter of Henry W., lawyer, of New York. She was the author of *The Wide, Wide World*, published 1850, under the *nom de plume* of Elizabeth Wetherell, immensely popular in this country and in Europe, translated into French, German, and Spanish, in the first 10 years the sale numbering 500,000 copies. *Queechy*, 2 vols. (1852), was almost as well received. She wrote also *The Law and the Testimony* (1853), a compilation of scriptural texts proving the doctrines of Christianity; *The Old Helmet* (1863); and other works, secular and religious, including *Books of Blessing*, and *Wych Hazel* (1876). Her sister, Anna Warner, writing over the signature of Amy Lothrop, has published a number of popular books, among them *The Fourth Watch* (1872); and *The Other Shore* (1873). Susan W. d. 1885.

WARPING, a mode of improving land, practiced where rivers bring down large quantities of mud, or where mud is brought up from estuaries by the tide. It is practiced in some of the valleys of the Alps; and the rich soil brought down from the mountains is thus arrested, and made to increase the fertility of fields. It is practiced also in England, on the tidal waters of the Ouse, Trent, and other rivers falling into the Humber. There are not many places in Britain where the process of warping is capable of profitable application.

WARRANTY, in law, is an assurance of a fact, coupled with an agreement to make the assurance good, or render just compensation if it prove not to be good. In a common law sale of chattels, if the vendor expressly warrant the title, he is, of course, bound by the terms of his agreement; but, even when no such stipulation is entered into, if the vendor have the article in his possession and sell it as his own, he is bound by an implied warranty that the vendee shall obtain a good title and have peaceable

possession, and that there are no liens or incumbrances against it except such as are specially designated when the sale is made. If a seller of goods expressly warrant their quality, the stipulation thus made survives the receipt and acceptance of them by the vendee; and, if it be broken, it gives to the latter a right to sue for damages or defend on the ground of breach of warranty when sued for the purchase price. The ordinary measure of his damages, in either case, is the difference between the actual value of the articles and what they would have been worth if they had come up to the warranty. Where no special agreement is made as to the quality of personal property sold, the civil law rule is *caveat venditor*—let the seller beware—or that a sound price carries with it the seller's implied warranty of sound quality. But the ordinary common law rule of both England and America, in such cases, is *caveat emptor*—let the buyer beware—or that there is no implied warranty of quality. Exceptions to this rule arise, however, in instances in which the buyer has been unable to examine the goods before making the contract, and where he has not been able to exercise his own judgment as to their quality. Hence, when articles, which the vendee cannot examine, such as goods at sea, are contracted to be sold under a special description, the vendor impliedly warrants that they shall be merchantable under that description; when a manufacturer undertakes to manufacture an article ordered for a certain work or purpose, he impliedly warrants that it shall be reasonably fit for the accomplishment of that purpose; a victualer or dealer in provisions, who sells them for domestic consumption, impliedly warrants that they are wholesome, and when goods are sold by sample, the purchaser not inspecting the bulk, there is an implied warranty that they are like the sample, that they are merchantable under the description given, and that the buyer shall have a reasonable opportunity to inspect them before he shall be bound to complete the purchase. But when food stuffs are sold as merchandise, to be resold by the vendee, there is no implied warranty that they are wholesome. And, if one specifically describe an article to be manufactured for him, and it be made according to his description, the manufacturer does impliedly undertake that it shall be suitable for any undisclosed purpose, to which the buyer may have intended it should be applied. In real estate law, the word warranty now usually denotes a covenant in a deed or conveyance, to the effect that the vendor will defend the title in the vendee against paramount claimants, and any acts of himself or those who may claim under himself; and that, if he fail to do so, he will be liable in damages to an amount not exceeding the purchase price of the property. In the law of insurance, a warranty is distinguished from a representation, in that the former is a statement or promise relating to the risk, which is inserted in the policy and must be strictly true or complied with or the contract will be void, while the latter is a mere collateral inducement outside of the contract, and needs to be only substantially complied with or performed.

WARREN is a place kept for the purpose of breeding game or rabbits.

WARREN, a co. in n.e. Georgia, drained by the Ogeechee and other rivers; 264 sq.m.; pop. '90, 10,957. Co. seat, Warrenton.

WARREN, a co. in n.w. Illinois, drained by Henderson river and Swan creek; 540 sq.m.; pop. '90, 21,281, chiefly of American birth, with colored. Co. seat, Monmouth.

WARREN, a co. in w. Indiana, bounded on the s.e. by the Wabash river; 360 sq.m.; pop. '90, 10,955. Co. seat, Williamsport.

WARREN, a co. in s. Iowa, drained by affluents of the Des Moines; 576 sq.m.; pop. '90, 18,269. Co. seat, Indianola.

WARREN, a co. in s. Kentucky, bounded on the n. by Green river; 530 sq.m.; pop. '90, 30,158. Co. seat, Bowling Green.

WARREN, a co. in w. Mississippi, having the Mississippi river for its w. boundary; 590 sq.m.; pop. '90, 33,164, chiefly of American birth, inclu. colored. Co. seat, Vicksburg.

WARREN, a co. in e. Missouri, having the Missouri river for its s.w. boundary; 435 sq.m.; pop. '90, 9913. Co. seat, Warrenton.

WARREN, a co. in n.w. New Jersey, having the Delaware river for its w. and n.w. boundary; 360 sq.m.; pop. '90, 36,553, chiefly of American birth, with colored. It contains Blue mountain and Jenny Jump mountain, crossing it from n.e. to s.w.; and Delaware water gap in the n.w. Co. seat, Belvidere.

WARREN, a co. in e. New York, having lake George for its e. boundary; drained by the Hudson and Schroon rivers; 940 sq m.; pop. '90, 27,866, chiefly of American birth, with colored. Among its mineral products is black marble, found at Glens Falls. Co. seat, Lake George.

WARREN, a co. in n. North Carolina, drained by the Roanoke and other rivers; 454 sq.m., pop. '90, 19,360, chiefly of American birth, inclu. colored. Co. seat, Warrenton.

WARREN, a co. in s.w. Ohio, drained by the Great Miami and the Little Miami rivers; 428 sq.m.; pop. '90, 25,468. Co. seat, Lebanon.

WARREN, a co. in n.w. Pennsylvania, drained by the Allegheny and other rivers; containing valuable petroleum wells; 855 sq.m.; pop. '90, 37,585, chiefly of American birth, with colored. Co. seat, Warren.

WARREN, a co. in central Tennessee, bounded on the e. by the Caney forth of the Cumberland and Rock river; 446 sq. m.; pop. '90, 14,413, chiefly of American birth, with colored. Co. seat, McMinnville.

WARREN, a co. in n. Virginia, having the Blue Ridge mountains on the s.e. boundary; forms a part of the Great Valley of Virginia; 234 sq. m.; pop. '90, 8280, chiefly of American birth, with colored. Co. seat, Front Royal.

WARREN, city and co. seat of Trumbull co., O.; on the Mahoning river and the Erie, the Pennsylvania Co.'s, and the Pittsburg and Western railroads; 55 miles s.e. of Cleveland. It has union graded schools, musical institute, gas and electric lights, electric street railroad, waterworks on the standpipe system, national and state banks, and daily and weekly newspapers; there are rolling, flour, paint, saw, and planing mills, linseed oil, tube, sprinkler, evaporator, and boiler works, and electric lamp, steel bath tub, and other factories. Pop. '90, 5973.

WARREN, a town in Bristol co., R. I., on Narragansett bay and the New York, New Haven, and Hartford railroad; 10 miles s.e. of Providence. It was incorporated in 1747; formerly included territory in Massachusetts; and has a town hall, the Hall public library, electric lights, national and state banks, weekly newspaper, iron foundry, and manufactories of cotton goods, braid, and twine. Pop. '90, 4489.

WARREN, Fitz Henry, 1816–78; b. and d. Brimfield, Mass. He emigrated to Burlington, Iowa, 1844, where he entered journalism and interested himself in politics; was appointed asst. postmaster-gen.; was a state senator, 1866, and minister to Guatemala, 1867–8. He fought in the union army during the civil war, and was breveted major-gen. He edited for a time the *Burlington Hawkeye*, and was connected with the *New York Tribune*, and *Sun*.

WARREN, Gouverneur Kemble, b. N. Y., 1830; graduated at West Point, 1850, and was commissioned in the engineers. He was employed in topographical work in the Mississippi valley, in the Pacific railroad explorations, and in Dakota and Nebraska; from 1859 to 1861 was assistant prof. of mathematics at West Point, and then became lieut.col. of a New York zouave regiment. He had commands at Big Bethel in the peninsular campaign and at the battles of Manassas, Antietam, Fredericksburg, Chancellorsville, and Gettysburg; was Hooker's chief topographical engineer, and chief engineer of the army of the Potomac. At Five Forks he led the combined 1st and 5th corps, and in the last year of the war had charge of Petersburg, and later, the Mississippi department. He left the volunteer service with rank of brevet maj.gen. and maj. of engineers in the U. S. army. He has since had charge of the construction of many fortifications, bridges, and harbor and river improvements. He d. 1882.

WARREN, Henry, president of the institute of painters in water-colors, was b. in London, Sept. 24, 1798. Warren's father inherited considerable wealth, which, however, he contrived to dissipate, and his children were left to shift for themselves. The subject of this memoir at first got a situation in a counting-house; but afterwards, having an intense love for art, was placed in the studio of Nollekens, the celebrated sculptor of the day. At Nollekens's, he was associated with Bonomi and Gibson. Through Benjamin West, Warren obtained an introduction to the sculpture-room of the British museum, where he practiced both drawing and modeling, and where he used to meet Haydon's pupils, Bewick, Christmas, and the Landseers. In 1818 he became a student of the royal academy, where he attended regularly for many years in the company of Etty, the Landseers, F. R. Lee, Webster, and others less distinguished. Warren's first paintings were in oil. He exhibited several of these from time to time at the academy. One was a subject from Collins's *Ode to the Passions*. Etty thought very highly of this picture, and Warren repeated it in water-color, and sent it for exhibition to the "New Society of Painters in Water-colors," of which he became a member at its foundation in 1835. Of this society, now known as the "Institute of Painters in Water-colors," Warren was president for over thirty years. The first great picture in water-colors exhibited by Warren was "The Happy Valley," from *Rasselas*—a piece embodying both landscape and figures, and displaying great power both in its composition and coloring. A great many of his subsequent pictures are on eastern subjects, leading some persons to suppose erroneously that he had lived a long time in Egypt, the Holy Land, Arabia, etc. Warren died in 1879.

WARREN, Henry W., D.D., b. Mass., 1831; graduated at Wesleyan university, Middletown, Conn., 1853, and joined the New England conference; for two years prof. ancient languages in Wilbraham academy; 1871–7, pastor Arch St. M. E. church, Phila., and St. John's, Brooklyn; in 1877, transferred to the Phila. conference and to Arch st. church; then to Spring Garden church in the same city; elected bishop, May, 1881; resides at Denver, Col.; is a counselor of the Chautauqua literary and scientific circle; has published *Sights and Insights*, a book of travels; *Recreations in Astronomy;* the Chautauqua primers on astronomy, and contributes to the denominational periodicals.

WARREN, James, 1726–1808; b. Mass.; graduated at Harvard in 1745. He was a merchant, who succeeded to a handsome estate on the death of his father in 1757. He also succeeded his father as high-sheriff of Plymouth county. He was elected to the legislature in 1766, and warmly advocated the rights of the colonists. He became president of the provincial congress on the death of Gen. Joseph Warren, and was for a time paymaster-gen. of the continental army. He was afterward speaker of the Massachusetts house of representatives.

WARREN, JOHN, 1753–1815; b. Mass.; graduated at Harvard, 1771; studied medicine, and settled at Salem, Mass. He took part in the battle of Lexington, and in June became a hospital-surgeon, afterward going to the front. He was also with Gen. Greene in 1778, and in the forces sent against Shay in 1786. He was one of the founders of the Harvard medical school, in which he was professor of anatomy. He delivered, in 1783, the first of the Boston 4th of July orations.

WARREN, JOHN COLLINS, 1778–1856; b. Boston; graduated at Harvard in 1797. He studied medicine with his father (Dr. John), and in London and Paris. He began practice in Boston in 1802, and soon rose to eminence. He was assistant-professor of anatomy and surgery at Harvard university, 1806–15; full professor, 1815–47; and professor emeritus, 1847–56. He was one of the founders and long an editor of the *Boston Medical and Surgical Journal*. He was also one of the founders of the McLean asylum for the insane, and of the Massachusetts general hospital, of which he was long chief-surgeon. In 1846 he used ether in surgery for the first time. He made a fine collection of specimens in anatomy and paleontology, now known as the Warren museum. Among his works are *Diseases of the Heart* (1809); *Comparative View of the Sensorial System* (1820); *Etherization* (1848); and *Mastodon Giganteus* (1855).

WARREN, JOSIAH (b. 1799, d. in Boston, Mass., April, 1874); was the author of a book entitled *True Civilization*, the central doctrine of which is that labor ought to be paid for by labor, an hour of a carpenter's work, for instance, by an hour of a doctor's. He put his theory into practice by establishing a "time store" in Cincinnati. Here labor values were exchanged for two years with some degree of success. In his young manhood he was a member of Robert Dale Owen's community at New Harmony, Indiana. It was the failure of this communistic scheme that led him to adopt a system which recognized the individual.

WARREN, JOSEPH, 1741–75; b. Roxbury, Mass.; graduated at Harvard in 1759, and became a physician in Boston in 1762. He took the place of Samuel Adams as orator at the 2d anniversary of the Boston massacre, and delivered an excellent address. In 1772 he was a member of the committee of correspondence. He was a member of the Suffolk county convention, which was called to oppose gov. Gage's proposed fortification of the s. entrance to Boston harbor, and as chairman of the committee appointed to remonstrate with Gage on that subject, drew up two papers, which were afterward laid before congress. In 1774 he was a member and president of the Massachusetts congress, and chairman of the committee of public safety. In March of the next year he was again the orator at the anniversary of the massacre. He had much to do with the success at Lexington, and in June, 1775, was commissioned maj.gen. He opposed the occupation of Charlestown Heights, advocated by Putnam and Prescott, thinking the American supply of ammunition too small to repel an attack. Overruled by a majority of the council, which resolved to fortify Bunker Hill, he went there as a volunteer, refusing to take the chief command offered to him by both Prescott and Putnam. As he was leaving the field among the last, he was killed by a ball in the forehead.

WARREN, MERCY (OTIS), 1728–1814; b. Mass.; sister of James Otis; wife of Gen. James Warren. She was active in the revolutionary movement, and carried on a correspondence with the chief public men of her time. She wrote *The Adulator*, a tragedy (1773); *The Group* (1775), both satirizing the royalists; *Poems, Dramatic and Miscellaneous* (1790); and a valuable *History of the Rise, Progress, and Termination of the American Revolution* (1805).

WARREN, MINTON, was born in Providence, R. I., in 1850, graduated from Tufts College in 1870, studied at Yale College, 1871–2, and at Leipzig, Bonn, and Strassburg, taking his degree of Ph.D. in 1879. The same year he was appointed associate in Johns Hopkins university, and in 1892 was made professor of Latin, which position he still holds. His principal writings are: *On the Enclitic Ne in Early Latin* (Am. Journ. Phil., vol. 2, 1881); *On Latin Glossaries with Especial Reference to the Codex Sangallensis*, 912 (Trans. Am. Phil. Assoc., vol. 15, 1885); *On the Contribution of Latin Inscriptions to the Study of the Latin Language and Literature* (ib. 1895).

WARREN, SAMUEL, D.C.L., 1807–77; b. Racre, Denbighshire, Wales, son of Samuel, LL.D.; studied medicine at Edinburgh, taking the prize on comparative jurisprudence. In 1828 he began the study of law at the Inner temple, London; practiced as a special pleader, 1831–37; in the latter year was called to the bar. He was conservative in politics, a strong supporter of lord Derby, and published *Ten Thousand a Year* in *Blackwood's*, 1839, in the interest of that party. Other publications are *Now and Then*, a novel (1847); *The Lily and the Bee* (1851), a poem, on the opening of the Crystal palace. In the same year he became queen's counsel; recorder of Hull, 1854–74; member of parliament from Midhurst, 1856; re-elected, 1857; resigned, 1859, having been appointed master in lunacy by lord Chelmsford.

WARREN, WILLIAM, b. Philadelphia, 1812, made his first appearance on the stage at the Arch Street (Philadelphia) theater, as "Young Norval," in which his father had made his *début*. In 1847 he became a member of the company at the Boston museum, with

which he long retained connection. Though little known outside New England, W. was one of the best comedians on the American stage. He d. 1888.

WARREN, William Fairfield, d.d., b. Mass., 1833; graduated Wesleyan university, Middletown, Conn., 1853; ordained and joined the New England Methodist conference, 1855; studied at Andover theological seminary, Berlin, and Halle; traveled in the east; elected professor of theology in the Boston Methodist theological seminary, 1861; president of the Boston university, 1873. He has published works on logic and systematic theology and *The Quest of the Perfect Religion* (1887). As a scholar he holds high rank.

WARRENSBURG, city and co. seat of Johnson co., Mo.; on the Black river and the Missouri Pacific railroad; 65 miles s.e. of Kansas City. It is the seat of the State normal school of the second district; contains electric light and street railroad plants, waterworks, about a dozen churches, and several banks; and has valuable sandstone quarries and mineral springs, grain elevator, flour and woolen mills, foundry and machine shop, and daily, weekly, and monthly periodicals. Pop. '90, 4706.

WARRICK, a co. in s.w. Indiana, bounded on the s. by the Ohio river; 390 sq.m.; pop. '90, 21,161. Co. seat, Boonville.

WARRINGTON, Lewis, 1782–1851; b. Va.; graduated William and Mary college, 1798; midshipman in the navy, 1800; was lieut. on the *Chesapeake* in her encounter with the British frigate *Leopard*, 1807; as master of the sloop *Peacock*, captured the British sloop-of-war *Épervier*, off cape Canaveral, Fla., 1814; received for this a gold medal from congress; took 14 British merchantmen, mostly in the bay of Biscay, 1814; became capt.; went to India; captured the English cruiser *Nautilus* in the straits of Sunda, 1815; commanded a squadron in the West Indies; was a member of the navy commission board, 1827–30; chief of ordnance and hydrography, 1847, till his death.

WARSAW, village and co. seat of Wyoming co., N. Y.; on the Buffalo, Rochester, and Pittsburg, and the New York, Lake Erie, and Western railroads; 47 miles s.e. of Buffalo. It contains a union school, gas and electric light plants, national and private banks, and a school library; and has several extensive salt works, iron foundry, a sanitarium, several factories, and weekly newspapers. Pop. '90, 3120.

WARSAW, a government of Russian Poland, adjoining Prussia, watered by the Vistula, Bzura, and Pilica rivers; about 5623 sq.m.; pop. '94, 1,499,264. The surface is level, and generally fertile. Capital, Warsaw.

WARSAW, formerly the capital of Poland (q.v.), now capital of the Russian, or rather Russianized, government of Warsaw, stands on the left bank of the Vistula, about 95 m. e. of Berlin by railway. Lat. of observatory, 52° 13′ n., long. 21° 2′ east. It stands partly on a plain, partly on rising ground sloping upward from the left bank of the river, extends over a wide area, and consists of the city proper, and a number of suburbs, several of which are beautifully built. Two iron bridges connect Warsaw with the suburb of Praga, on the right bank of the Vistula. The streets are mostly narrow, though in several instances they are broad and handsome. The Vistula at Warsaw is broad, shallow, and ever-changing in its sandy course, and is navigable for large vessels only when, after thaw, rivers of melted snow pour down into it from the Carpathians, or when it is swelled by the autumn rains. Seen from Praga, on the right bank, the castle, standing on a steep ascent, has a most imposing effect. Attached to the Saxon palace are a spacious court and gardens, which are considered the finest promenade in the city. Among the other buildings there are many palaces; the cathedral of St. John (dating from 1250), a Gothic building of great beauty, containing statuettes and many interesting monuments, among which is one by Thorwaldsen; the Lutheran church, the loftiest building in Warsaw, and numerous other places of worship, including synagogues. There are several large and memorable squares, as the Sigismund square, containing the monument, erected by Ladislas IV., in honor of his father, Sigismund III. In this square, on April 8, 1861, 40 unarmed and unresisting Poles were massacred. The citadel, erected by the emperor Nicholas, for the express purpose of intimidating, and, if necessary, destroying the city, commands, from its situation, every part of Warsaw. The university, broken up by the emperor Nicholas after the insurrection of 1830, was re-established by decree, 1869, and is attended by about 1000 students; and besides this institution, there are several minor colleges, fine museums, gymnasia, etc. Woolen and linen fabrics, chemicals, sugar, and leather, and a vast number of other articles are manufactured. Pop. '97, 614,752.

WARTBURG, War of the, the name given both to a grave poetic contest, which is represented to have taken place on the Wartburg, and also to a poem in the Middle High-German dialect, which commemorates the event. At the time when the aforesaid dialect had attained its highest literary development, and its poets enjoyed a brilliant reputation, Hermann, the munificent Landgraf of Thuringia, had made his court a sort of refuge or home for the *irritable race*, as well as for many other people. It could hardly fail, under the circumstances, that quarrels and jealousies should abound; and, in fact, allusions to these are sufficiently distinct in several of the most distinguished writers who lived at the Thuringian court—e. g., in Wolfram von Eschenbach and Walther von der Vogelweide. But soon after the conception of these things underwent a sort of

mythical transformation, and the occasional temporary and natural rivalries of the poets were changed into a particular and premeditated contest for superiority in poetic skill; and to the list of those poets who actually had intercourse with each other at Eisenach were now added others partly historical, and in part purely fictitious characters—e.g., the virtuous Schreiber, Bitterolf, Reinmar (subsequently confounded with Reinmar von Zweter), the almost mythical Heinrich von Ofterdingen, and the wholly mythical Master Klingsor, the Transylvanian magician and astrologer. On the basis of this historico-mythical tradition, and under the formal influences of the then much admired songs of emulation, riddle-contests, and ecclesiastical plays, there was composed, about the year 1300, a strange, obscure, unharmonious poem in two parts, called *Kriec von Wartburg*. In the first of these, executed in a long and artistically managed measure, and entitled *Tone des Fürsten von Thuringia*, Heinrich von Ofterdingen challenges the other poets to a contest in verse—the fate of the vanquished to be death—and asserts the excellence of Leopold, duke of Austria, over all the other princes. Victory, however, inclining to the Eisenachers, Heinrich calls in Klingsor to his aid, who, on his part, fights his verse-battle against Wolfram by the assistance of evil spirits, with riddles and dark science. With distinct reference to Klingsor's "black art," the simpler and shorter measure of this second part is called *Schwarze Ton*. Throughout the whole poem, which may be regarded as the first attempt at a secular drama, but which is rather an intermediate link between the lyric contest and the drama, one may trace an unmistakable imitation of Wolfram's style of poetry. The author is unknown. From the inequality of the style one is disposed to conclude that several hands were employed in its composition. The poem, which has been much overrated in modern times, does not seem to have exercised any particular influence on literature. In a prose form the story of the Wartburg contest first appears—in the Thuringian chronicles—after the beginning of the 14th c., and probably owes its origin to the poem. The poem was printed in a separate edition by Ettmüller (Ilmenau, 1830), and is also to be found in Bodmer's and Von der Hagen's collection of the *Minnesinger*.—See Von Plotz, *Ueber den Sängerkrieg auf Wartburg* (Weimar, 1851).

WART-HOG, *Phacochœrus*, a genus of *suidæ*, closely resembling the true hogs in most of their characters, and particularly in their feet, but remarkably differing from them in their dentition; the molar teeth being much like those of the elephant, and replacing one another in the same manner. There are two triangular incisors in the upper jaw, and six small ones in the under; the tusks are lateral, very large, project far from the mouth, and are bent upward; there are six or eight molars in each jaw. The head is very large, and the muzzle very broad; the cheeks furnished with large wart-like excrescences, so that the appearance is altogether very remarkable and uncouth. The species are all natives of Africa. They feed very much on the roots of plants, which they dig up by means of their enormous tusks. The African Wart-hog, or Haruja (*P. Æliani*), a native of Abyssinia and of the central regions of Africa, from the coast of Guinea to that of Mozambique, is nearly 4 ft. long, with a naked slender tail of one foot, is scantily covered with long bristles of a light brown color, and has a mane sometimes 10 in. long, extending from between the ears along the neck and back. Another species is found in the s. of Africa (*P. Æthiopicus* or *pallasii*), the *valke vark* of the Dutch colonists at the cape of Good Hope. The incisors of the latter fall out at an early age, those of the former are persistent.—A closely allied genus is *potamochœrus*, of which there are several species, as the *bosch vark* of Cape Colony (*P. Africanus*), which is nearly black, with whitish cheeks having a central black spot; and the Painted Pig of West Africa (*P. penicillatus*), which is reddish, with black face, forehead, and ears. The species of *potamochœrus* frequent swampy grounds, and sometimes receive the name of Water-hog. They have longer ears than the true water-hogs, tapering and ending in a pencil of hairs; the face is elongated, and has a huge protuberance on each side. The flesh of all the wart-hog and water-hogs is in high esteem. They are hunted by dogs, which are often killed in the encounter with them. They are much addicted to fighting among themselves.

WARTON, Joseph, d.d., was born at Dunsfold, Surrey, in 1722. His earlier education he received from his father, the Rev. Thomas Warton, sometime professor of poetry at Oxford. At the age of 14 he was sent to the great school at Winchester, whence, in 1740, he was transferred to Oriel college, Oxford, where, four years afterward, he took his degree of b.a. After passing the intermediate years as a curate at Chelsea and elsewhere, in 1748 he was presented by the duke of Bolton to the rectory of Winsdale, near Basingstoke, a living of no great value, yet sufficient to determine his marriage with a Miss Damon, to whom he had been engaged. Previous to this he had become known as a writer of verse in the *Gentleman's Magazine*, Dodsley's *Museum*, etc., and as the author of a volume of *Odes and other Poems*. In 1751 he went abroad with the duke of Bolton; and after his return he issued, in 1753, an edition of Virgil, with a translation of the *Eclogues and Georgics*. This, with the critical notes and dissertations appended to the work, met with great approval, and subsequently procured him from the university of Oxford the degree of m.a. In 1756 appeared the first volume of his chief literary performance, the *Essay on the Writings and Genius of Pope*, the second and concluding volume of which was not given to the world till 1782. Venturing, as he did, to question the positive supremacy which it was then fashionable to attribute to Pope, Warton

did not by this work attain any very instant increase of popularity; but the value in relation to the literature of the time, of the critical principles announced in it, as also in his other more casual essays, has since been sufficiently recognized. In 1755 Warton was appointed second master of Winchester school, of which he became head in 1766. Soon after, he revisited Oxford, and had conferred on him the degrees of bachelor and doctor of divinity. Of preferment in the church, he had subsequently his full share. By the good offices of Dr. Lowth, bishop of London, he was made, in 1782, a prebendary of St. Paul's; and the living of Thorley, in Hertfordshire, was conferred on him. He obtained besides, in 1788, a prebend in Winchester cathedral, and the rectory of Easton, which he soon after exchanged for that of Upham. The mastership of Winchester he resigned in 1793, and devoted himself to the preparation of an annotated edition of Pope, which was completed in 9 vols. 8vo in 1797. At his death, Feb. 23, 1800, he was engaged on a similar edition of Dryden, of which he had published two volumes. Though Warton's reputation has not survived as a poet, yet it certainly has as a critic, along with that of his more distinguished brother.—See *Biographical Memoirs of Rev. Joseph Warton, D.D.*, by Rev. John Wooll, A.M. (1806).

WARTON, Thomas, the younger brother of the preceding, was born in 1728, at Basingstoke, in Hampshire, of which place his father had then become vicar. His earlier education he received chiefly at home from his father; and in 1743 he was entered at Trinity college, Oxford, where, in 1750, he took his degree of M.A. The year after, he obtained a fellowship. He remained at the university, employed as a tutor; and in 1757 he was made professor of poetry, in which capacity he was much esteemed as a lecturer. In 1767 he took his degree as bachelor of divinity, and was soon after presented to the living of Kiddington by the earl of Lichfield. In 1782 that of Hill Farrance, in Somersetshire, fell to him by favor of his college; and these two unimportant pieces of ecclesiastical preferment were the only ones he ever enjoyed. Very early he became known as a poet, and in 1754 he published a volume entitled, *Observations on the Fairie Queene of Spenser*, which established his reputation as one of the first critics of the day. In a second edition of the work, issued in 1762, it was expanded into two volumes. Of Warton's miscellaneous literary activity, no account need be given in detail. The work by which he is now chiefly remembered is his *History of English Poetry*, the first volume of which was published in 1774. Two other volumes followed in 1778 and 1781, but at his death the work remained unfinished. In its wealth of information regarding the earlier portion of our literature, the book remains to this day unrivaled. As a poet, also, Warton takes distinct, if not very high rank. In 1777 he published a collection of such of his scattered pieces as he deemed most worthy of being reprinted, and the acceptance it met with is shown in the successive editions of 1778, 1779, and 1789, as also in the fact, that on the death of Whitehead, the poet-laureate, Warton had the honor, such as it might be, of being selected to succeed him in the office. The last work on which he was engaged was an elaborately annotated edition of the minor poems of Milton. Of this, published in 1785, a carefully prepared re-impression was issued the year after his death, which took place suddenly on May 21, 1790. In 1802 a new edition of his poems was published, with a life of the author by Mr. Mant.

WARTS (sometimes known in surgery by their Latin name *verrucæ*) are collections of lengthened papillæ of the skin (q.v.), closely adherent and ensheathed by a thick covering of hard dry cuticle. From friction and exposure to the air, their surface presents a horny texture, and is rounded off into a small button-like shape. Such is the description of the simple wart, which is so commonly seen on the hands and fingers (and rarely on the face or elsewhere) of persons of all ages, but especially of children. Among other varieties of warts are: (1) One to which the term *verruca digitata* has been applied. It is more elongated in shape, and less protected by cuticle than the preceding. It is said to occur nowhere but on the scalp of women of adult age, and sometimes to occasion great annoyance in brushing and combing the hair. (2) *Subungual warts*, growing, as their specific name implies, beneath or at the side of the finger or toe-nails. They originate beneath the nail, and as they increase, they crop out either at the free extremity or the side of the nail, and are usually troublesome, and often very painful. They are generally of syphilitic origin. (3) *Venereal warts*, caused by the direct irritation of the discharges of gonorrhœa or syphilis, and occurring about the parts which are liable to be polluted with such discharges. They attain a larger size, and are more fleshy and vascular than other warts.

Nothing is known of the causes of warts further than the third variety is induced by an irritating discharge, that the malignant form of wart which is the beginning of chimney-sweepers' cancer is caused by the irritation of soot, and that persons engaged in dissection and *post-mortem* researches are especially liable to them; hence we may infer they are always due to some local irritation. Venereal warts are certainly contagious; with regard to others, we cannot speak positively. In some cases, but not invariably, blood from a wart is capable of producing similar warts when applied to the skin. In consequence of the capricious way in which warts often spontaneously disappear, there are numerous popular charms for their removal, several of which may be found recorded in the pages of *Notes and Queries*. Common warts are so apt to disappear, that

they may be often left to themselves. If it is desired to remove them, glacial acetic acid is perhaps the best remedy; it must be applied with a camel-hair pencil till the wart is pretty well sodden, care being taken not to blister the neighboring skin. One or at most two applications are usually sufficient. Nitrate of silver and tincture of iron are popular and general applications. Small warts hanging by a neck, may often be very simply removed by the moderately tight application of an elastic ligament (for example, a small broken elastic ring) to the base. The wart usually shrivels up, and falls off within a week. The other varieties of warts must be left to the surgeon.

WARWICK, a co. in s.e. Virginia, having the James river on the s.w.; 165 sq.m.; pop. '90, 6650, chiefly of American birth, with colored. Co. seat, Newport News.

WARWICK, a municipal and parliamentary borough, chief t. of the county of the same name, stands in the middle of the county, on the Avon, 21 m. s.e. of Birmingham. It is a very ancient town, and contains many ancient and interesting buildings and institutions. Of these the most notable is Warwick castle, the principal residence of the earls of Warwick, beautifully situated on a rocky elevation, 40 ft. high, on the banks of the Avon. Of this edifice, Guy's tower, 128 ft. high, was built in 1394; and Cæsar's tower, still more ancient, is 147 ft. high. The interior, before the castle was partly burned, Dec. 3, 1871, was remarkable for its splendor and elegance, and has been restored in similar style. There are numerous charities, with schools, libraries, etc. Agriculture and general trade afford employment to a large number of the inhabitants. Warwick returns one member to the house of commons. Pop. '91, of municipal borough, 11,905; of parliamentary borough, 39,102.

WARWICK, a town in Lancaster co., Pa., adjoining the borough of Lititz (q.v.). Pop. '90, 3153.

WARWICK, a town in Kent co., R. I.; on the Providence and Pawtucket rivers, Narragansett and Greenwich bays, and the New York, New Haven and Hartford railroad; containing a large number of villages, principally engaged in the manufacture of cotton, woolen, and print goods. It was settled in 1642, named after the earl of Warwick, and called by the Indians, Shawomet. There are national and savings banks in the village of Centreville, and the town is well supplied with churches, public schools, libraries, electric lights, and electric railroads. Drum Rock, a balanced rock of great size, can be moved by a child, and makes a sound which can be heard for miles. Pop. '90, 17,761.

WARWICK, Guy, Earl of, a hero of early English legend. He is said to have lived in Saxon times, during the reign of Athelstan in the 10th century. There is no reason to believe that he ever lived at all. The legend of Guy is of Anglo-Norman origin, but does not go back, so far as known, beyond 1300. Chaucer alludes to sir Guy in the *Canterbury Tales*, and Shakespeare in *Henry VIII.* (if that work be his), to sir Guy and Colbrand, a Danish giant, whom Guy fought.

WARWICK, Richard de **BEAUCHAMP**, 12th Earl of, 1381–1439; succeeded to the title in 1401. He participated in the war with Owen Glendower and the Percys, and was at the battle of Shrewsbury. In 1413 he went to France as a commissioner to treat for peace, and the next year attended the council of Constance. In 1415 he was capt. of Calais, and, 1418, ambassador to Burgundy. He was presently made earl of Aumerle. He was regent of France, 1425–28, and of France and Normandy, 1437–39.

WARWICK, Richard **NEVILLE**, Earl of, K.G., popularly named the king-maker, was eldest son of Richard, earl of Salisbury, and Alice, daughter and heiress of Thomas Montacute. He was born about 1420, shortly before the accession of Henry VI. Lord Richard Neville, as he was then styled, early manifested his distinguished bravery and brilliant personal qualities in a hostile incursion across the Scottish marches, in which he accompanied his father, the earl of Salisbury. He became the most powerful nobleman in the kingdom, by his marriage with Anne, daughter and heiress of Richard de Beauchamp, earl of Warwick. He not only acquired by this alliance the broad lands of the Warwick family, but was created earl of Warwick, with succession to the heirs of his wife. He is the most prominent figure in the civil war of the roses, one of the darkest periods of English history. The duke of York gained his support by his marriage with lady Cecille Neville; and when the barons declared the incapacity of Henry VI., and chose the duke to be protector of the kingdom, Warwick led into the field his well-tried borderers of Wales. The Yorkists and the Lancastrians first met at St. Albans in 1455, when Warwick, rushing suddenly into the town at the head of his men, mainly won the battle by his impetuous onset. He was rewarded with the government of Calais—"then," says Comines, "considered as the most advantageous appointment at the disposal of any Christian prince, and that which placed the most considerable force at the disposal of the governor." He also obtained command of the fleet for five years. In 1458 he sailed from Calais with five large and seven small vessels, and attacked a fleet of 28 ships, belonging to the free town of Lübeck. After a battle of 6 hours, he took 6 of the enemy's vessels. In 1460 he landed in Kent at the head of his troops, and entered London amid the acclamations of the people. He defeated the queen's army, near Northampton, with great slaughter, and obtained possession of the person of the king. Richard, duke of York, now advanced his claim to the throne. Queen Margaret raised an army to rescue the king; and the duke committed the idiotic monarch to the custody of the duke of Norfolk and Warwick, while he advanced to Wakefield to attack the Lancastrians. The duke was taken, and put to death; and Warwick's father, the earl of Salisbury, with twelve other Yorkist

chiefs, was beheaded at Pontefract. Another battle at St. Albans was won by the Lancastrians, but Edward, earl of March, now duke of York, accompanied by Warwick, marched boldly upon London, which was throughout Yorkist, and Edward was proclaimed king by the style of Edward IV. The next battle was that of Towton, near York. The Lancastrians had retaken the pass of Ferrybridge, on the river Aire, and Warwick, in despair at the loss of so good a position, rode up to Edward, and dismounting, shot his own horse through the head, as a signal for an attack from which there could be no retreat, exclaiming: "Sir! let him flee who will flee; but by this cross" (kissing the hilt of his sword) "I will stand by him who will stand by me!" The Lancastrians were defeated with immense loss; and Edward, returning to London in triumph, was crowned June 22, 1461. The battle of Hexham was followed by the capture of Henry; and Warwick, who had been left in command in London, placed the deposed king on a horse, under whose belly his feet were fastened, and thus led him through Cheapside to the tower. Warwick having been authorized to negotiate with Louis XI. of France for the marriage of his sister-in-law, the princess Bonne, of Savoy, to king Edward, could not brook the king's sudden marriage with Elizabeth Woodville, and seemed inclined to show that he could pull down as well as set up kings. He was now at the height of his power. To the earldoms of Warwick and Salisbury, with the estates of the Spencers, he added the offices of high-admiral and great-chamberlain, together with the lord-lieutenancy of Ireland and the government of Calais. Comines states the income of his offices at 80,000 crowns a year, besides the immense revenues accruing from his patrimony; yet he had the meanness to accept a secret pension and gratuities from Louis XI. After being sent into honorable banishment by means of embassies to France, Burgundy, and Brittany, he gave his daughter in marriage to George, duke of Clarence, without asking Edward's permission. He soon afterward broke out into revolt against Edward, and concluded a treaty with queen Margaret, by which it was agreed that her son, prince Edward, should espouse Anne Neville, Warwick's daughter, and that in failure of issue, the crown should devolve on Clarence. King Edward escaped to Holland, and Henry VI. resumed the sovereignty. Edward, however, raised a body of Flemings and Dutchmen, and, landing near Hull, advanced toward London. He gave battle to king Henry's army, commanded by Warwick, at Barnet, April 14, 1471. The battle was memorable and important. Warwick and his brother, Montague, were left dead on the field, and with them fell the greatness of the house of Neville. This fatal battle, followed by the decisive engagement of Tewkesbury, completed the defeat of the Lancastrians, and concluded the sanguinary war of the roses. It appears (Fenn's *Letters*) that every individual of two generations of the great families of Warwick and Somerset fell on the field or on the scaffold, a victim of these sanguinary contests. Warwick is the most conspicuous personage of these disturbed times. He kept open house wherever he resided, and daily fed at his various mansions 30,000. He loved turbulence for its own sake, and was ready to make or unmake any king, according to the caprice of the moment, and in order to show his power.

WARWICK, Robert **RICH**, Earl of, about 1590–1658; succeeded to the title, 1618, and was a descendant of lord-chancellor Rich. He joined himself to the Puritan movement, took great interest in the colonization of Rhode Island, and was a friend of Thomas Hooker, the founder of Hartford. In the parliamentary wars he was a supporter of the Puritan cause, in 1642 served under Northumberland as lieutenant of the fleet, and during the protectorship of Cromwell was chosen to bear the sword of state in the latter's presence.

WARWICKSHIRE, one of the midland counties of England, bounded on the w. by Worcestershire, on the n. by Stafford and Leicester shires, and on the s. mainly by that of Oxford. Area, 885 sq.m.; pop. '91, 805,070. The surface, though presenting no lofty hills, is marked by gentle eminences and vales. The n. districts of the county were formerly occupied by the forest of Arden, of which there are still remains; and the scenery, in general remarkably rich and charming, is varied by moor and heath. The principal rivers are the Avon, flowing from the n.e. to s.w., and the Tame in the north. The soil varies much in quality, being cold and heavy on the higher and more exposed positions; while in more favorable districts it is as a rule good. The chief manufacturing centers in Warwickshire are Birmingham and Coventry; the brass jewelry, iron, and steel-pen trades are carried on in the former, and ribbon-weaving and watchmaking in the latter. Of minerals, coal, chalk, lime, and marl are found. It contains four parliamentary boroughs, six municipal boroughs, and ten market towns. The county returns four members to the house of commons.

WASATCH, a co. in n.e. Utah, area, 3444 sq. m.; pop. '90, 3595, chiefly of American birth. In the n. portion are the Uinta mountains; the Wasatch mountains lie along the w. border, a long range extending from the n. border of Utah nearly to the Colorado river, the highest peaks of which are 11,500 ft. high, their sides broken by cañons varying in depth from 2000 to 5000 feet. The summits of this range rise from a plain varying from 4250 to 6000 ft. in height, and reach a further elevation of from 6000 to 7000 ft. above the valley. Silver is found. Co. seat, Heber.

WASCO, a co. in n. Oregon, having the Columbia river on the n. and on the w. the Cascade range of mountains, including Diamond Peak, and the Blue mountains on the s.e.; area, 3315 sq. m.; pop. '90, 9183. Co. seat, The Dalles.

WAS'ECA, a co. in s. Minnesota, 430 sq.m.; pop. '90, 13,313. Co. seat, Waseca.

WASH, a wide estuary on the e. coast of England, between the counties of Lincoln on the n.w. and Norfolk on the s.e., is about 22 m. in length, and 15 m. in average breadth. It is surrounded by low and marshy shores, and receives the rivers Witham, Welland, Ouse, Nen, and Nar. The estuary for the most part is occupied by sandbanks, dry at low water, and between these sandbanks are the channels through which the rivers mentioned flow into the North sea. On both sides of the channel by which the Ouse falls into the sea, considerable tracts of land have been reclaimed. Anchorage is afforded to vessels by two wide spaces or pools of water, called respectively Lynn deeps, opposite the coast of Norfolk, and Boston deeps, opposite the Lincolnshire coast.

WASHBURN, a co. in n. western Wis.; formed, 1883, from part of Burnett; 864 sq.m.; pop. '90, 2926. It is drained by branches of the St. Croix. Co. seat, Shell Lake.

WASHBURN, Cadwallader Colden, ll.d., b. Maine, 1818; brother of Elihu B. and Israel, jr. He removed to the west in 1839, and lived in Illinois and Wisconsin. He was elected to congress in 1856 and served three terms. He was a delegate to the peace conference of 1861, but soon after raised and became col. of a cavalry regiment, commanded an expedition into Mississippi, and later was at the head of divisions in the Vicksburg campaigns, held a command under Gen. Banks in Louisiana, and reached the rank of maj.gen. of volunteers. From 1867 to 1871 he was again a member of congress, and in the latter year was elected governor of Wisconsin by the republican party of that state. He was largely engaged in the manufacture of lumber and flour in Wisconsin and Minnesota. He d. 1882.

WASHBURN, Charles Ames, b. Maine, 1822; educated at Bowdoin college. He went to California in 1850, became editor and afterward proprietor of the *Alta California*. He was editor and proprietor of the San Francisco *Times*, 1858–61. He acted with the republican party from its foundation, was a presidential elector in 1860, and was minister to Paraguay, 1861–68. Violence was offered to his legation by Lopez, and Washburn saved them only by calling the aid of an American squadron. D. 1889.

WASHBURN, Edward Abiel, d.d., 1819–81; b. Boston; graduated, Harvard college, 1838; studied theology at Andover seminary, and at the divinity school of Yale college, graduating 1842; was licensed as a Congregational minister, but after preaching six months entered the Episcopal church, and was ordained by bishop Eastburn, 1844; was rector of St. Paul's, Newburyport, Mass., for seven years; spent six months in China, 1851, returning through India, Egypt, Palestine, and Europe, 1853; became rector of St. John's church, Hartford, and prof. of church polity at the divinity school, Middletown; rector of St. Mark's church, Philadelphia, 1862; of Calvary church, New York, 1865; visited Europe, 1871, as a delegate of the evangelical alliance. Dr. Washburn was a member of the committee on Bible revision, a translator of part of Lange's commentaries, a contributor to reviews and other periodicals, an eloquent speaker, and a broad churchman in his views, fraternizing cordially with ministers and Christians of other denominations. His intellectual power was great, and he was admired equally for a certain symmetry and nobleness of character.

WASHBURN, Emory, ll.d., 1800–77; b. Mass.; graduated at Williams college in 1817. He was admitted to the bar in 1821, and practiced his profession at Worcester, 1828–56, attaining a high rank. He was a justice of the court of common pleas, 1844–47, and governor of Massachusetts, 1854–55. He had previously served in both branches of the state legislature, and had declined a whig nomination for congress, though in a district surely whig. The overthrow of the whigs in Massachusetts by the "know-nothings" cut short his political career. He afterward acted with the republican party, and was in the Massachusetts legislature as chairman of the judiciary committee the last year of his life. He was prof. in the Harvard law school, 1856–76. His most important works are *Treatise on the American Law of Real Property* (1860–62) and *Law of Easements and Servitudes* (1863).

WASHBURN, Israel, 1784–1876; b. Mass.; in 1806 went to Maine, and two years later became a shipbuilder on the Kennebec river, near the site of Richmond. He afterwards settled in Livermore, Maine. He was the father of Samuel Benjamin, William Drew, Elihu Benjamin, Cadwallader Colden, Charles A., and Israel, jr.

WASHBURN, Israel, jr., ll.d., b. Maine, 1813; admitted to the bar, 1834. He continued to practice his profession with success till 1850, when he was elected to congress; and he was four times re-elected. He was governor of Maine, 1861–62, and in 1863 was appointed collector of Portland. He d. 1883.

WASHBURN, William Burritt, ll.d., b. Mass., 1820; graduated at Yale college, 1844. He became a manufacturer in Greenfield, Mass., and president of a bank. He was a member of the Massachusetts senate in 1850, and of the house in 1854. In 1862 he was unanimously elected to congress on the republican ticket, and was four

times re-elected. He was governor of Massachusetts, 1871–74, when he resigned, having been elected to fill the remainder of Charles Sumner's term in the U.S. senate. His term expired in 1875. He was a trustee of Yale and Smith colleges. He d. 1887.
